The two principal causes for the loss of energy from dynamite are, its disadvantageous application, and the escape of confined gases without performing any useful work. Incidentally there is a waste of energy in the jarring and loosening of the rock away from the point of breakage and in a useless comminution of a portion of the broken material. A practical miner might suggest that there was a further waste in a useless breaking of air-pipes and machines, the knocking out of stulls, and in the scattering of rock over the level. In spite of the imperfect utilization of the expended energy, which amounts from the above figures to less than 0.1%, and in spite of the many injurious effects of dynamite when used in confined workings, it still continues to hold first place as a means of breaking rock in mining operations.

The question that suggests itself from the above figures and which it is the purpose of this article to briefly discuss, is whether it is possible to improve upon the above conditions, or whether the use of dynamite presents inherent advantages that it is impossible to overcome.

Anyone who has had intimate experience with underground work will agree that the conditions arising from the explosion of dynamite underground are, to say the least, undesirable. They are the primary cause of the tramp miner, or, to put it differently, they are the cause of the practical miner being a tramp. Enticed by high wages offered as compared with other vocations, but finding the physical conditions unendurable, he migrates to new fields, only to find the conditions repeated. This is not a hypothetical condition. It is one which actually exists and one which I, though a college graduate, have been compelled to face and endure in the course of my training to become a mining engineer. A consideration of these conditions at once suggests that the proper place for the use of dynamite would be upon the surface in the generation of power where its injurious effects would be less pronounced. There has not been, as yet, any system devised whereby this program could be put into effect. So far as I know, no attempt has been made to utilize the power of dynamite in the running of machinery and few would care to experiment in this direction.

Many attempts have been made to excavate rock with machinery alone, particularly in the oft repeated attempt to produce a tunneling machine, which has invariably been a failure. I am not familiar with the exact causes assigned for the failure of such machines, but a consideration of the results obtained and power employed in the drilling of rock strongly suggests why any machine designed for the cutting of the entire face of a tunnel has been and will continue to be a failure. If we assume that a modern stoping machine having a 2 in. cylinder, weighing 75 lb., and consuming 40 cu. ft. of free air per minute at 90 lb. pressure, will drill a $1\frac{1}{2}$ in. hole at the rate of 5 in. per minute, and from this deduce the power and weight of a machine necessary to remove the entire face of a tunnel, we obtain the following results. To remove a 3 ft. round from a 4 by 7 ft. face in 6 hr. actual working time, there would be needed a machine weighing 4200 lb. and consuming 2400 cu. ft. of free air per minute. The cost for power alone, on a basis of $10 per horse-power month, would amount to $9 per foot of advance. If the items of labor, steel, and supplies be considered, it can readily be seen that the cost of any such method must be prohibitive without considering the difficulty of moving such a machine from one point to another in the mine.

The lesson that this argument and the results of actual trials teaches is that if a tunnel or similar opening in rock is made without the use of explosives, it must, for economical reasons, be by breaking rather than by cutting or grinding.

STUDENT.

Los Angeles, August 5.

Exports of Iron and Steel

An increase of over $51,000,000 in the exports of iron and steel manufactures and a decrease of over $4,000,000 in the imports of this class of merchandise are striking characteristics of the foreign commerce of the United States in the fiscal year just ended. Iron and steel manufactures exported aggregated $230,725,351 in value, against $179,133,186 in 1910 and $183,982,182 in the former high record year, 1908. The exports of iron and steel manufactures in the fiscal year 1911 were $51,592,165 in excess of those of the preceding year and $46,743,169 in excess of the highest record ever made prior to 1911. Ten years ago, in 1901, the exports of iron and steel manufactures amounted to but $117,000,000; twenty years ago, $29,000,000, and thirty years ago, $16,500,000, in round terms. The chief growth has occurred in the last dozen years, the total having never touched the $100,000,000 line prior to 1900, in which year it was $122,000,000. By 1905 it had risen to $135,000,000; by 1908, to $184,000,000; and in 1911, as already indicated, the total was $231,000,000.

A MAN may inhale with comfort air containing 3% of carbon dioxide and 16% of oxygen, if such air is not under any greater pressure than that of ordinary air at the surface of the ground.

Concentrates

Most of these are in reply to questions received by mail. Our readers are invited to ask questions and give information dealing with the practice of mining, milling, and smelting.

CLAY SLATE is not the only rock that swells upon exposure to the atmosphere, for decomposed granite and many other igneous rocks are known to do the same thing.

A CRADLE is not an economical apparatus for washing gravel, this is shown by the fact that where it is used the ground is often washed several times over, often times with almost as good results. It is the best device available in early work, and is still used in many places.

TITANIUM is being used with great success in making steel rails. The New York Central line has given rails treated with ferro-titanium a thorough test in the Grand Central terminal yards, and now requires that all rails made for its lines shall be treated with titanium alloy.

HIGH COSTS of mining are often due to poor management, particularly in the amount and distribution of the labor. One California gold mine recently examined had 78 men on the pay-roll, of which only 23 were in the ground. To supply 15 stamps, 8 machines were kept in service.

REALGAR is a soft, orange-red mineral, of a resinous lustre, and having the composition As_2S_2. It occurs with the arsenic minerals, the most notable localities being in Borneo and Hungary. The artificial sublimate is used in fireworks and in signaling, and also, to some extent, as a pigment.

FREE gold, when present in an ore even in quite small amount, is readily seen in the pan or horn-spoon, though as little as one ounce of ore be taken for the test. Ore worth no more than $2.50 per ton will show a decided 'prospect' in pan or spoon, when manipulated by experienced hands.

LEAD POISONING results from inhaling the dust or fumes of lead in mines or metallurgical works. A dilute solution of sulphuric acid, one drop of acid in 100 drops of water, is said to be an antidote for lead poisoning, the acid attacking the lead oxide in the system and forming lead sulphate, which is harmless.

ASBESTOS, as a material of engineering, is unique. Soapstone has great heat-resisting qualities and is a good electric insulator, but it can only be used where massiveness is permitted. Mica also withstands heat and provides excellent dielectric resistance. Its brittleness bars it from use as an insulator in many cases. Asbestos may be used much more widely than either.

DIAMONDS first came from India, the famous mines of Golconda being between Hyderabad and Masuhpatam: In 1728 diamonds were found in Brazil, having been for some time thrown away with the other gravel obtained in gold washing. For a time these mines were very famous, but are now completely obscured by the South African fields, which were discovered in 1867.

DEPTH of some of the main shafts in the Kalgoorlie, Australia, goldfield is as follows: Great Boulder Proprietary, 2800 ft.; Sons of Gwalia, 2440; Ivanhoe, 2270; Great Boulder Perseverance, 2100; Golden Horse Shoe, 2100; Chaffers, 2100; Associated, 2000; Lake View & Star, 2000; Kalgurli, 1850; South Kalgurli, 1800; Associated Northern, 1100; Hainault, 950; Golden Ridge, 500.

QUICKSILVER when fouled, by lead or other mineral substances, will not readily form into globules, but if disturbed shows a tendency to form in elongated drops. Retorting is the best method of cleaning foul mercury, but this must be done at as low a heat as possible or the base metal will pass over with the quicksilver, and its condition be little if at all, improved. The addition of dilute nitric acid to a bottle of impure quicksilver tends to purify it.

VALUE of an oil as fuel is in proportion to the combustible matter it contains as shown by its heating value. This value may be expressed in small calories per gram or B.t.u. per pound. Sulphur, moisture, and earthy matter lower the heating value of an oil and decrease the furnace capacity; they also may have a deleterious effect on boiler and furnace, and may impair the operation of burners.

THERMODYNAMIC efficiency of the vapors from distillate or gasoline in a gas-engine is low, on account of their high explosiveness, which causes pre-ignition, thus limiting compression to so low a value that it requires about 20,000 B.t.u. per brake horse-power, while the slow-burning producer-gas will use only 9000 or 10,000 B.t.u. per brake horse-power, or an increase in utility of 50 to 55 per cent.

AIR-HAMMER DRILLS have only been adapted as yet to drilling 'uppers' in which the drillings run out by gravity from the holes. The limiting angle is about 20° when ribbed steel is used; as the rotation of the steel helps to convey the drillings down the inclined sides of the hole. On this account ribbed steel should be used rather than hexagonal or round steel, especially as both these require shaping before use.

METALLURGY is the art of extracting metals from their ores, and of purifying or refining them to the quality required by the metal-working industries. It is a branch of applied chemistry. The metallurgical industries form a highly important part of the national resources; on them the nation depends for iron, steel, copper, brass, gold, silver, lead, zinc, aluminum, in fact for all the supply of metals used in arts and industry.

DIAMOND-DRILLING was not extensively carried on at Kalgoorlie during 1910. The largest amount was done in the Associated from the 1900-ft. level. In the Great Boulder an attempt was made to cut the main lode from each new plat; in the Ivanhoe from the 2000-ft. level out east to test some unknown country; and in the Kalgurli for prospecting ahead of cross-cuts. At Eyre, near the great Australian Bight, boring was performed for a water supply for the trans-Australian railroad. Fresh water was struck at 1270 feet.

DOUGLAS FIR is used as a mine timber, both in the square and round forms, in the western part of the United States. Squared mine timbers of Douglas fir also go to Pennsylvania and to foreign countries. It is frequently preferred to all other available species because of its durability and strength, and because of the desirable sizes in which it may be obtained. Where a supply of this timber is at hand, it also goes largely into temporary work such as lagging, sills, posts, and caps. When it cannot be conveniently procured, substitutes are frequently found in lodgepole pine and western yellow pine.

COPIES of monthly reports are often distributed to all the foremen in a large works. When the number desired is too great to be conveniently made by manifolding and yet not enough to print, any of the common types of duplicating machine will prove useful. When one of these is not available, a convenient method to follow is to take an unused sheet of carbon paper, back it with a wax sheet (soft blotting paper will do), and write on it with a typewriter just as though it were ordinary paper. This gives a negative which can be used to make as many blue-prints of the reports as are required. The report will be in blue letters on a white ground.

TORONTO, CANADA

Porcupine Reconstruction Progresses Rapidly.—No More Relief Funds Needed.—Two Months Extension for Assessment Work Granted.

The principal news from Porcupine at present is the progress in the work of reconstruction, which is going forward rapidly, though necessarily under difficulties owing to the congestion of freight and the shortage of timber. Much has been done lately by the T. & N. O. Commission to prevent undue delays and provide adequate siding accommodation, and material and supplies are now moving forward freely. A large number of buildings are in process of construction. The relief committee announces that no more funds are needed for the relief of the immediate requirements of the fire sufferers, the amount subscribed to date amounting to $52,294. The provincial government has extended the time for doing assessment work on claims in the Porcupine district for two months. A number of prospectors are now returning to work on their claims. The Dome Mines has a large force at work constructing a spur to connect its property with the railway. The Pearl Lake has ordered a plant, including a 12-drill compressor and a 200-hp. motor which will be run with power from the Mattagami river. In the Jupiter a 4-ft. vein rich in native gold was found in cross-cutting at 100 ft. A party representing Bewick, Moreing & Co., of England, including E. C. Moreing, Sir William Bell, Graham Prentice, J. L. Loring, and G. Lovell, visited the Porcupine camp last week. It is stated that the company has concluded negotiations with a syndicate represented by L. S. Collard, G. T. Hartt, and R. Howard, under which the exploitation of 52 Porcupine claims in Murphy and Wark townships will be undertaken by the company. The Vipond will put in a new mill and power-plant, including an 8-drill compressor. The main working shaft is to be sunk to the 200-ft. level, and cross-cuts run at this depth to tap No. 2 and 3 veins. A new vein of quartz found on the Dome property since the fire has been discovered to enter the Dome Extension. At the Hollinger reconstruction is progressing well. The company is manufacturing its own lumber, the mill on Miller lake turning out between 15,000 and 20,000 ft. per day. The foundations for the compressor and boiler are about finished. At the Crown Reserve claim some rich ore has been found at 50 ft. on No. 2 vein. The shaft will be put down to 100 ft. Another shaft is going down on a vein which shows 12 ft. of quartz on the surface. Some important sales have lately been made. The North Thompson claim has been bought by John C. Hicks, of New York, at a price said to be about $250,000. Baron G. von Polenz, of Berlin, has bought the two Christ claims in Tisdale, south of the Hollinger, on account of British investors, for $235,000. The Routley location near Pearl Lake has been sold to Daniel F. Yost, C. A. Burdick, and other New York men, for a price not stated. The McAulay-Brydge location in Bristol township has been taken over by B. E. Cartwright for $50,000.

The stock market, both as regards Porcupine and Cobalt issues, has been characterized lately by inactivity, with a decidedly downward tendency due partly to the season, but emphasized in the case of some of the mines by unfavorable rumors. Nipissing has experienced a decided slump, one of the reasons given being that the profits of the first six months of the year, amounting to $858,891, fell materially short of the dividend requirements. This is easily accounted for by the shortage of power early in the year. Moreover, prospecting for the discovery of new orebodies has been on a limited scale this season, in view of the intention of the company to undertake hydraulic prospecting as soon as a plant can be installed. This will include a turbine pump with a capacity of 4800 gal. of water per minute, and a 700-hp. motor. Trenching has not been found altogether satisfactory, and it is proposed to remove the oreburden entirely by the hydraulic process so that no veins may be missed. The pinching out of the veins of the Temiskaming in the diabase formation raises an important question as to the permanence of some of the mines at depth. Willet G. Miller, Provincial Geologist, and Cyril W. Knight, are now making a further study of the Cobalt field as revealed by the developments of the last few years, especially as regards the ore-bearing possibilities of the diabase. The Trethewey mill has been overhauled and the fine-grinding apparatus discarded. Automatic samplers have been installed. With the mill treating 2500 tons per month there is upward of two years' supply of ore in sight. At No. 4 shaft near the Hudson Bay the vein has been found at the second level. The Rochester has contracted with the Lumsden Mining Co. to explore the former property from the 250-ft. level of the Lumsden, where a 4-in. vein of smaltite showing a little silver has been found. At the Buffalo the extensions to the cyanide plant have been completed and it is running satisfactorily. During July the mill ran 575 hours and treated 3487 tons of ore averaging 40 oz. silver before treatment, the expenses of the mill for the month being $4622. The Millerette mine, Gowganda, has shipped 30 tons of concentrate, the first output of its new mill.

WASHINGTON, D. C.

Mine-Safety Demonstration.—Meeting at Pittsburg.

Thirty thousand miners are expected to attend the great national mine safety demonstration to be held in Pittsburg, Pennsylvania, October 26 and 27, under the auspices of the Federal Bureau of Mines, the American Red Cross, the Pittsburg Coal Operators' Association, and the United Mine Workers of America. The date, which was originally set for September 16, has been changed so that Mr. Taft may be present on the second day, October 27, to witness a mimic mine explosion in a temporary steel gallery on Forbes field, an exhibition of rescue work by helmeted miners, following the explosion, and to review the parade of miners. The President will make an address and will present souvenir prizes to the miners taking part in the first-aid and rescue-work exhibitions. Walter L. Fisher, secretary of the Interior Department, the Governor of Pennsylvania, and Joseph A. Holmes, the Director of the Bureau of Mines, will also be present. The general arrangements for the demonstration are in charge of H. M. Wilson, engineer-in-charge for the Bureau of Mines. The demonstration, the purpose of which is to teach greater safety in mining, will begin the morning of October 26, at the experiment station of the Bureau of Mines. The first day will be devoted to the interests of the mine operators, mine owners, mining engineers, and superintendents of mines. There will be an explosion of coal dust in the experiment gallery and tests of safety lamps in gas. The dangers of electric sparks in gas and coal dust will also be shown in one of the galleries. A class of miners will be trained in the use of the oxygen helmet. In the afternoon, the operators, engineers, and superintendents will witness an actual mine explosion in the experimental mine of the Bureau at Bruceton, Pennsylvania, twelve miles from Pittsburg. Coal dust will be allowed to accumulate in the mine, and black powder, against the use of which in mines where there are dangerous conditions the Bureau is agitating, will be used. In other words, the Bureau's experts will carry out in this mine all the bad practices which they believe lead to explosions. The next morning, October 27, the demonstration will take place on Forbes field, the Pittsburg baseball park, in the presence of the President of the United States and other distinguished visitors. A temporary steel gallery will be erected on the playing field and the cause of the recent great explosions in coal mines will be dramatically shown in an explosion of coal dust. Immediately following the explosion, members of one of the rescue corps of the Bureau, in their oxygen helmets, will rush into the smoke-filled gallery and go through the work of rescue. Supposed victims of the explosion will be brought forth and given first-aid. Expert rescue teams from the principal coal mines of the country will give friendly exhibitions and then the miners will pass in review of the President.

NICARAGUA, PIS PIS DISTRICT

Work Stopped at Bana Cruz.—Title Difficulty Delays Bonanza Sale.—Electric Power for La Luz & Los Angeles.—New Mining Laws.

Charles D. Kaeding, who, at Bana Cruz, has been opening up the Union American group, under option, in the interests of San Francisco operators, has discontinued all work and has left, with N. J. Kelsey, for San Francisco, by way of New York. The properties, while showing a fair grade of ore, were over-priced for the amount of ore in sight. The Bonanza property, recently under option to Bradley and Mackenzie, is doing better than ever before. The sale of the property has been indefinitely postponed owing to limitations of title, part of which has been cleared up by the abrogation of all concessions on April 28. Joseph Lapierre, the owner, has left for a year's tour of Europe, leaving P. A. O'Brien in charge; the mill has been overhauled and the eight Huntingtons are running steadily. The cyanide plant is being remodeled and preparations made for the treatment of the slime by the use of a vacuum filter.

Under the management of Paul Rener, the owner, the Concordia mill keeps steadily at work, crushing about 25 tons per day of good grade ore; the mill has 10 stamps, 750 lb. weight each. This property is under option to John F. Cowan of Salt Lake City. W. E. Connelly, formerly of the Constancia mine, is mine foreman. The Constancia, with the only really modern mill in the district about half completed, has been idle for some time on account of financial difficulties. The mill was to consist of 10 stamps, 750 lb., a Hardinge conical mill, Trent agitators, and Oliver filter. The process was to have been the all-sliming cyanide process. The property is now under option to Mr. Cowan. Work still continues on the new mill for the Dos Amigos mine. No further steps have been taken toward a mill on the Guillermina property. The Josephina property is idle.

The La Luz & Los Angeles property continues to be one of the largest producers in the country and has many thousands of tons of high-grade ore in sight. The present difficulty is power, as under the combination of gasoline, water, and steam-power the power costs about $25 per horse-power month. Steps are being taken toward the use of electric power, and the company's electrical engineer, Mr. Watson, of Pittsburg, has been investigating the various sources of power in the vicinity. Harry J. Amphlett is manager. Although the La Luna property has plenty of ore, the mill is incomplete and a temporary shut-down took place on June 17. The Lone Star, lying close to the Bonanza, was under option to Messrs. Bradley and Mackenzie, and since the postponement of the sale has been running 30 stamps most of the time. Norman McInness is owner and is in Managua on legal business. T. W. Bouchelle is metallurgist and acting manager. Operations on the Mars mine have been temporarily suspended, owing to Mr. Sherrick's trip to the States with Mr. Lapierre, and Mr. Loebner's trip to Managua on legal business. The Mining Exploration Co. has brought suit against the owners of the property for $60,000 for alleged breach of contract.

The Panama property, Sydney J. Sydney, manager, has been arousing considerable interest in the district on account of the approaching start in operation of the new mill. The mill is supplied with ore from the mine by a wire-rope tramway, which has given some trouble, but is now said to be operating satisfactorily. The ore is to be crushed in rolls and tube-mills, agitated with cyanide solution, and filtered on a filter of Mr. Sydney's own design. The mill will be in operation as soon as boiler capacity can be provided. Nothing has been done on the Rosa Lee property for over a year. A 3-stamp prospecting mill is being placed on the property and should be in operation by August 1. There is a large tonnage of good-grade ore in sight. Montgomery Rener is owner and manager. The Potosi adjoins the La Luz & Los Angeles and is owned by Jose Aramburu. No work has been done to show the extent of the orebodies and the owner is making arrangements to put in a mill.

An attempt is being made to remodel the Siempre Viva mill and construct a filter for the treatment of the slime. In the meantime the 20 stamps are running on oxidized ore from the old stopes. About 8000 tons of average $8 ore has been reclaimed from the abandoned ground with as much more in sight. In addition, a foot-wall vein has been cross-cut parallel to the main vein in the foot wall, a 40 ft. distance, that shows 6 ft. of $14 ore. Henry B. Kaeding is manager. The Santa Rita mine, in the [illegible] district, has been having trouble with the steam plant, but is running smoothly now. The Trinidad, Richard Lehmann, owner, has been idle for some years. A little prospecting was done lately, but nothing of any importance.

By decree of April 28, later ratified by the Chamber of Deputies, all onerous mining and other concessions were declared abrogated and the ground thrown open for location. This removes the greatest bar to the progress of the mining industry in this country. A commission is also at work reforming the mining laws, having the particular point in view of allowing the location without discovery of mineral of sufficient ground on the dip of a known vein to protect the extralateral rights. With these points conceded and the concessions canceled, there should be apparent a decided impulse ahead in the mining industry here.

DURANGO, COLORADO

Activity in La Platas.—Neglected.—Mancos Country.—A New Find near Durango.

There is more activity in the La Plata mountains this season than there has been for many years, owing to several promising finds and to the increased number of producing mines. The idleness of two of the best properties, the Idaho and May Day, due to litigation over apex rights, has, however, greatly curtailed the output. The Incas mine, contiguous to the above-mentioned properties, is maintaining a production of two to three cars a week of a good grade of gold-silver ore. The Comstock, which was the first producer in the district and in the early days yielded $70,000 or more from surface workings, is being developed by a cross-cut adit. Three shifts are at work and the vein will soon be cut below a body of $100 ore from which a carload was shipped last spring, when the melting snow made further operations in the shaft impossible with the equipment at hand. The ore contains a comparatively rare mineral, cosalite—a sulphide of bismuth and lead—and is rich in the precious metals, specimens assaying several hundred ounces gold as well as considerable silver. The Copper Hill mine, at the mouth of Bedrock gulch, is shipping from surface workings one or two carloads a week of ore carrying 9 to 12% copper, several ounces silver, and some gold. The Neglected, which has produced at least $500,000 from its 150-ft. shaft, is said to have a large tonnage of $20 to $30 ore in sight, and a deal is now on for the sale of a three-fourths interest for $750,000. Cyanide tests have been made by a Denver specialist and a 100-ton plant is contemplated in case the sale is made. The owners of the mine have begun the construction of a five-mile wire-rope tramway to the Hermosa river, where it is intended to build the mill.

Recent developments have greatly stimulated prospecting, and the East and West Mancos territory, which has been dormant for several years, is being ransacked by prospectors, with the result that several promising finds have been made in abandoned workings and elsewhere, one of the best being a 4-ft. fissure in an adit which was driven by Durango men ten to twelve years ago. The strike was made by Mancos prospectors, and it is understood that the owners of the Idaho mine have taken hold of the property. Pannings show free gold as coarse as grains of wheat. On the East Mancos at the Doyle Consolidated sixty men are working, most of them on the construction of a large cyanide plant and roasting furnaces, for the reduction of the base ore of these mines. About four miles below the Doyle mine the Ben Hill M. Co. is sinking on a promising contact fissure about 2 ft. wide, which carries sufficient free gold to make good shipping ore; and farther down the river, near the railroad, a company of Mancos men have an encouraging showing of gold ore and will soon make a shipment to the Durango smelter.

A rich find is reported about ten miles northwest of Durango. O. N. Kee, a prospector who was sent out recently by the grubstake committee of the Denver Chamber of Commerce, sent some samples to Denver which assayed 22.36 oz. gold and 26.5 oz. silver per ton. The Cumberland mine, at the head of the La Plata river, which is under lease and bond to Telluride men, recently started its mill and a satisfactory recovery is reported.

BUTTE, MONTANA

Air-Hoist Not Yet Working.—Colorado to Ship.—Tuolumne.—Labor Contracts.

Minor changes have been necessary in the new compressed-air hoisting plant of the Diamond mine of the Anaconda company before it would work satisfactorily. It was expected that the hoist would be started August 1, but it has not yet been put into commission. It is now thought that in another week it will be working all right, and then the High Ore mine will be shut down and work started to make changes there. The Anaconda Copper Mining Co. has been made defendant in a suit for $5,000,000 damages, the alleged value of ore mined from the Wild Bill lode claim, mined by the company, but of which one Edward Hancock claims to own a tenth interest, and he claims that he has never received an accounting of the ore mined from the property by the Anaconda company since August 1899.

Orders have been received from F. A. Heinze, president of the Davis-Daly Copper Co., to begin shipments from the Colorado mine in Butte, the only promising property owned by the company. The tramway from the mine to the Northern Pacific railway has been connected with ore-bins on the latter road and during the coming week mining will be started in the Colorado. The mining will be done on the 1400 and 1700-ft. levels where considerable ore has been blocked. It is expected that 100 tons per day will be hoisted and shipped alternately to the Washoe and East Butte smelters until it is determined from which the better returns are obtained, the rates given the Davis-Daly being about the same from each smelter. The ore in the Colorado is not of high grade, the average in copper being between 3 and 4%, with unusually high silver content. It is reported that a new orebody has been found on the 1400-ft. level, about 4000 ft. west of the shaft of the Colorado. Heinze's Stewart mine in the Coeur d'Alene district is becoming an important producer and is earning good profits. About 500 tons of concentrating ore is being shipped daily to the mill, and about 2000 tons of first-class ore and of concentrate is shipped each month to the smelter at East Helena.

The Tuolumne Copper Mining Co. is engaged in erecting a new hoist at the Tuolumne mine. It is not likely that the new plant will be ready for operation before November 1. The company is at present producing copper at the rate of 500,000 to 650,000 lb. per month. Tuolumne has been one of the unfortunate new companies of Butte that has suffered from misrepresentation by over enthusiastic and overly interested brokers, who have repeatedly represented that the company is producing 1,000,000 lb. per month from ore that yields 160 lb. of copper per ton. Tuolumne is mining only its richest ore and the average is 5 to 6%. The policy of secrecy established by the North Butte company at Butte is being closely maintained, although the impression is permitted to get out that developments are gradually showing an improved condition in the mine. The station and skip pocket at the 2800-ft. level have about been completed and in a week or so the new cross-cut south to the Edith May vein will be started. W. D. Thornton, president of the Greene-Cananea Copper Co., who is in Butte, does not confirm the rumors of an early resumption of dividends by the company, although he expresses himself well pleased with the improving conditions of the mines.

The Western Federation of Miners, recently in convention in Butte, refused to strike from its laws a provision adopted two years ago, opposing contracts by local unions with mining companies or other employers regarding a scale of wages. The action is important in view of the fact that the contracts of the Butte, Anaconda, and Great Falls unions with the Anaconda Copper Mining Co., will expire next spring. Many members of the Butte unions wanted the privilege of renewing the contract, but the majority of the delegates opposed it. The action does not mean, however, that the Butte miners contemplate a demand for an increase of wages, but it will leave them free to continue working at the present rate of $3.50 per day just as long as they want to work for that. In other deep-mining camps wages have lately been raised by employers to $3.75, and it is possible that a request for an increase will be made.

GOLDFIELD, NEVADA

Goldfield Merger Plans.—Tonopah Belmont in Goldfield.—Consolidated Output and Plans.

Engineers in the employ of the Goldfield Merger Mines Co. are now engaged in preparing plans for the beginning of an elaborate system of development, including the sinking of a four-compartment, 2000-ft. shaft. The control of this company was recently acquired by W. A. Clark, George Wingfield, and others interested in promoting a revival of activity in their district. It is stated by an officer of the newly formed Deep Mines Co. that Mr. Clark's decision to enter the Goldfield district was based upon the reports made for Spurr & Co. by George H. Garrey, formerly of the United States Geological Survey, and that Mr. Spurr will act as geologist and consulting engineer for the new concern. The exact point at which the new shaft will be sunk has not yet been determined, though it has been announced that it will be on the Moonshine claim of the Gold Horn group, not far from the centre of the property. The engineers may yet decide to enlarge and sink to depth the old company shaft on the Moonshine, already over 600 ft. deep. Reports to the effect that J. R. Finlay will act as manager for the new company are not confirmed. Plans are now being worked out by the engineers but the work of sinking may not begin for another month.

It is announced by M. B. Cutter, president of the Tonopah & Goldfield railroad and a large stockholder of the Tonopah Belmont Co., that a new shaft and other development work of an extensive character will at once be started on the Goldfield Belmont, adjoining the Daisy and Black Butte on the north and which is practically owned by the principal stockholders of the Tonopah Belmont. The new work is under the supervision of Frederick Bradshaw, engineer for the Tonopah Belmont company. The Goldfield Belmont has been shipping ore of excellent grade from the 300-ft. level and lessees have taken a considerable amount of $100 ore from the 50 and 150-ft. levels, assays in the winze from the latter yielding to $1400 per ton. The new work will be conducted on the Quartzite No. 1 claim adjoining the Black Butte on the northeast, and development and extraction will continue at the old shaft. This ground was studied last January by Mr. Garrey.

The customary production of 950 tons daily is being made by the Goldfield Consolidated Mines Co. and it is probable, from apparently authentic reports, that the August output will be considerably larger than that of either of the past two months. It is said that large bodies of excellent ore have been exposed between the 1000-ft. level of the Clermont and the 1200-ft. of the Grizzly Bear, particularly on the latter level and on the intermediate, which was started 100 ft. on the dip of the vein below the 1000-ft. level of the Clermont. There is no doubt of the fact that the company is reserving a large tonnage of high-grade ore in the mines, which is left standing and blocked, and which may be drawn upon at any time for the purpose of enriching the mill-heads. It has been the object of the management to increase the tonnage treated to the utmost capacity of the mill and to keep down the mill-heads to the lowest figure compatible with the maintenance of the present dividend rate, in order that all ore of value might be treated at once, thus avoiding a second handling of any low-grade material.

NEW YORK

Market News.—Copper Figures.—Arizona Copper Co.—Guggenheims and Development Company of America.—Porcupine.

General conditions in the stock market have become acutely bad within the past week. There has been a drastic slump, and the brokers have exhausted their vocabulary saying things concerning the Stanley committee's investigation of the Steel Corporation and are placing all the blame for financial stagnation upon so-called meddlesome politicians. The Copper Producers' report for the month of July shows domestic deliveries decreased some 5,000,000 lb., while exports increased approximately 75,000,000 lb., a higher figure than has been reported any time since last December, and an increase of 4,500,000 lb. above the export figure of a month ago. It may be entirely unjust, but there is a suspicion that not all of the wonderful export demand is actual. There may be no justification for the thought, but the suggestion made a month ago is strongly emphasized by the current figures. The decrease in surplus copper stocks was, in round numbers, 20,000,000 lb., while production was 112,167,934, a smaller return than any month in the year, save February. Accumulated stocks are now smaller than any time in 1911. The small refinery output, decreasing domestic deliveries, and an abnormal export figure, make up an interesting copper situation with latent possibilities. It is apparent that some of the factors in the copper metal market do not altogether relish the publicity brought about by the Producers' Association, and if it were possible to disband, or drop the organization without criticism, it can hardly be doubted that the Association would be allowed to expire. The Government is said to have undertaken an investigation of the Association, and if an order forcing the disbandment of the Association should follow, protest, if any, would undoubtedly come from the consumers instead of the producers. Perhaps one of the reasons for desiring a little less publicity may be found in the commanding position of the porphyries as shown in the recent quarterly report of the Utah Copper Co. The company met a reduction of one-quarter of a cent per pound by merely increasing its output and so automatically lowering costs.

While not yet made public in detail, it is understood that the committee which has been inspecting the properties and plant of the Arizona Copper Co. has made a satisfactory report. The site for the new smelter is yet a matter of discussion, but it is thought that the company will be largely guided by the suggestion of L. D. Ricketts.

It is being repeated that the Guggenheims are looking over the various subsidiaries of the Development Company of America, which include Tombstone Consolidated, the Imperial Copper, and the Saddle Mountain properties. The Development Company of America has been trying to devise a satisfactory plan of organization without any remarkable success, and there is no doubt a sale on any acceptable basis would be welcomed.

The worst set-back which mining interests have received in the East for a long time is the ruthless demoralization of the list of Porcupine issues. A short time since, preparations were being made for the launching of a full-fledged, electrifying mining boom. Some big deals were talked of as completed; the entrance of the Consolidated Gold Fields was made much of, with the result that they were no sooner in, than they publicly announced their exit, with the statement that they thought they were getting too much free advertising. Recently there has been a demoralizing slump in Hollinger, in which the Bewick-Moreing syndicate had acquired 50,000 shares and held an option for a like amount in addition. Now the option has not only been allowed to lapse, but the original 50,000 shares is believed to have been dumped into the market, helping the decline from $16 to $10.50. One of the chief factors against the early normal development of Porcupine was the absurd valuation placed on raw claims by owners and prospectors in the first days of the camp. Many mining men and promoters were anxious to have a stake in the new field but balked on paying exorbitant prices for prospects. For the present, Porcupine is dead marketwise, and its revival will be harder to accomplish than was its initial start. Most of the New York newspapers refuse to allow the name of the district to appear in the paper, either in advertising or in reading matter. The Englishmen appear to have not lost their faith in the camp, although Hollinger now stands a failure as a market matter, much as did Nipissing in the early days of Cobalt. When the Guggenheims dropped Nipissing, the Cobalt share activity received a blow, from the effects of which it has never fully recovered. Now Bewick, Moreing & Co. have placed Hollinger in much the same plight.

LONDON

Bullfinch Failures.—Closing the Foxdale Mine in the Isle of Man.—Wheal Kitty.

A year ago there was an abortive boom in England in connection with shares in Bullfinch mines in West Australia. Owing to the vigorous opposition to these schemes on the part of *The Mining Magazine* and others, the hollowness of the pretensions of many of the companies was recognized before things got too far. The companies that were actually floated are now beginning to sink. The Bullfinch East has decided to wind up, but this was not an important flotation. Much more interest has been aroused by the announcement that the Bull Ant is a failure. This company was promoted by Messrs. Doolette, and the London stockbrokers, Lionel Robinson, Clark & Co. The company still has £63,000 cash, and some shareholders want this distributed and the company wound up. The promoters, however, are averse to this course, and are disposed to do something for the shareholders. They therefore have offered to give one share in the Bullfinch Proprietary, their more prosperous company, in exchange for two shares in the Bull Ant. The shareholders will therefore get a rather longer run for their money.

The lead and zinc mines of Great Britain are either slowly dropping out of existence or are gradually decreasing in output. The Welsh mines are now producing less every year. An old landmark that is to disappear is the Foxdale silver-lead mine in the Isle of Man, that has been worked continuously since 1852 by the Isle of Man Mining Co. Up to 1890 the distributed profits were about £7000 or £8000 per year, and since then the dividends have gradually fallen and nothing has been paid since 1907. Some months ago it was found that the margin of profit had disappeared, and operations were only continued on the basis of lower wages. The men, however, did not agree to this arrangement for long, and struck work. The directors had no alternative, therefore, but to close the mine.

The progress of J. H. Collins' tin mine, the Wheal Kitty & Penhalls, at St. Agnes, Cornwall, continues to be satisfactory. The policy has been to mine lower-grade ore during the period of higher prices of the metal. The ore raised and treated during the first half of 1911 was 7816 tons, yielding 98 tons of concentrate, which sold for £11,602, as compared with 7636 tons, 110 tons, and £11,091, respectively, during the previous six months. The price obtained averaged £119 per ton, as compared with £100. The profit was £1875, out of which £1492 was written off for depreciation and for shaft-sinking. Dividends at the rate of 10% per annum on the preferred shares absorbed £841, part of which was provided out of the balance £1967 brought forward from the previous half-year. The equipment of the new Sara's shaft with pumps and haulage gear has been completed down to the present sump, and sinking will be resumed shortly. The development covered 1691 ft., or 1 ft. for every 4.6 tons of ore hoisted. The work on or near the adit-level has proved satisfactory, and a lode averaging 20 in. wide and containing 33 lb. of recoverable black tin per ton has been followed for 384 ft. The prospects at the Gooninnis sett recently acquired are not particularly hopeful. In future, much more ore will be drawn from the Sara's section.

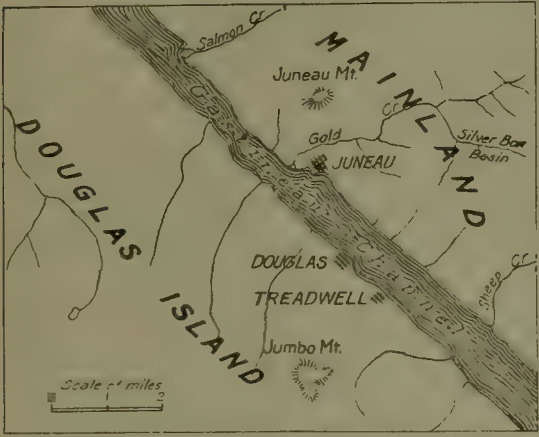
General Mining News

ALASKA

Juneau District

The total production of the Alaska Treadwell G. M. Co. for the month ended July 15 is valued at $188,297.39. The ore crushed amounted to 76,020 tons, and 1465 tons of sulphides was saved. The total realizable value of the output was $182,171.73. Operating expenses amounted to $86,729.95, leaving a net operating profit of $95,441.78. Construction expenses for the month are extraordinarily large, as they include the entire machinery bills for the new central hoist and crushers. They are given as $64,791.91. The ore milled yielded $2.41 per ton. Over 650 ft. of development work was done.

The report of the Alaska Mexican G. M. Co. for the month ended July 15 shows that 17,806 tons of ore was crushed, yielding $2.62 per ton. The total production for the month is valued at $46,627.60, with a realizable value of $46,161.33. Operating expenses amounted to $27,356.32, leaving a net operating profit of $18,805.01. The machinery bills for the new central hoist and crushers brought the construction expenses to $21,620.23. Over 160 ft. of development work was done. The sulphides saved amounted to 424 tons.



MAP SHOWING DOUGLAS ISLAND.

Prince William Sound

A small lode assaying $17.20 has been found at Kimball pass by G. A. O'Connor. It is more than 6 ft. wide.

A rich quartz vein recently was discovered a mile and a half from Ptarmigan Drop road-house by Lars Holland and Tom Hooleson.

An important discovery of free gold has been made on Shoup glacier and many claims have been staked. Specimens brought from the original lode discovered by Cliff Johnson and Captain Cameron are reported to have assayed $172 and $242 per ton. Eight lodes have been uncovered.

Work has been started on the Whalen & Anderson property on Shoup bay. Specimens showing free gold can be picked up almost anywhere there, according to press reports. The property is 1600 ft. above sea-level.

The Owl M. Co. recently imported two pack-horses for Shoup bay. They are the first horses there.

Seward Peninsula

A large dredge is being constructed at Port Clarence for dredging placer tin deposits.

ARIZONA

Cochise County

A milling plant will be constructed in the near future by the Fluorine M. & M. Co. of Pearce. The vein-filling contains fluorite, phonolite, rhyolite, and andesite as well as quartz. Free gold has been found. The east drift on the 110-ft. level will be connected with shaft No. 1. A winze will be sunk on the same level between No. 1 and 2, to follow a rich vein found there. C. S. Mounonier is treasurer.

Gila County

Inspiration Copper Co. on the first of the month had 23,018,000 tons of ore developed and averaging over 2% copper, and 2,516,000 tons partly developed, making a total of 25,534,000 tons. Operation is continued steadily.

CALIFORNIA

Butte County

(Special Correspondence.)—Richard R. Grass is constructing a 6-ton Bryan roller mill at Forbestown for custom ore from the small mines of this district. A larger mill later may be built half a mile from here.

D. C. Mitchell with ten men is engaged in development work at the Carlisle mine, which formerly was operated by Eugene Schmidt of San Francisco.

Forbestown, August 14.

Monterey County

(Special Correspondence.)—While surface indications at Gorda indicate gold ore, very little development work has been done. The Plaskett brothers are getting on an average twenty-five 100-lb. sacks of rich free-milling gold ore per day from a 3-ft. vein. The brown oxide ore from this vein assays about $3000 per ton. They are uncovering ore which has been covered by settling of the earth-crust on the steep mountain-side and are sacking it to prevent it from being carried away by the next winter's rains. Over 300 ft. of the vein is in sight, and they will have sacked over 100 tons from surface ore before following the vein beneath the crust. Mr. Bushwell, at Bushwell's camp, is sacking rich free-milling ore from a well defined vein in decomposed slate.

Plaskett, August 9.

Nevada County

(Special Correspondence.)—The North Star M. Co. has commenced the reopening of the Nevada City mine, one of the Champion group. The clearing out of the old drain tunnel is under way, and the shaft will be repaired and re-timbered. An electric hoist has been delivered at the shaft and will operate from the 400-ft. level, when the shaft has been intersected by the drain tunnel. The Nevada City mine comprises two claims, but the property has never been developed extensively. Within a few weeks it is believed the new electric pump at the Providence shaft will be in commission. The pump has a capacity of 750 gal. per min., with a vertical lift of 980 ft., and will be operated by a 250-hp. electric motor. In the main Champion workings considerable development work is progressing. More men constantly are being added to the force, and the North Star people are showing a disposition to conduct work on a broad scale. The surveying party recently sent out by the St. Gothard Gold Co. to determine costs, etc., of increasing water-power facilities, has practically completed its labors. Within a short time it will be known what action the directors will take. In the meantime the property, generally known as the Delhi, remains idle for lack of sufficient power. Othello Scribner and associates of San Francisco are conducting vigorous work at the West Point, in the Rough & Ready district, four miles below Grass Valley. It is stated that crosscuts and drifts are going ahead, while good ore has been stoped. This is the company that recently acquired the California mine, in the same field. The Pennsylvania-W. Y. O. D. mine, at Grass Valley, is reported to be improving under new management.

Nevada City, August 12.

San Diego County

The Universal M. & D. Co. has been organized under the Arizona laws for development work in the Pine Valley district. It is planned to treble the depth of the workings and to increase the capacity of the mill on the property from 10 to 20 tons. Later a cyanide plant will be added. The ore deposits at the Universal, or Nobles, tuite occur at the contact between mica schist and a granitoid rock, in pockets, stringers and in a porphyritic dike. So far only the first two have been prospected. The officers of the company are Henry A. Cogswell, president; Charles A. Arnold, vice-president; R. E. [illegible], secretary; and Thomas A. Wetzel, treasurer and general manager. Railroad connection will be made at Campo, 18 miles distant from and about 2000 ft. below the mine. The line is under construction.

The Balaklala Copper Co. has commenced dismantling its smelter at Coram. It is reported that 100,000 lb. of steel material has been sold to the McCormick-Saeltzer company of Redding. A rumor is finding belief that the Balaklala and other companies are interested in the proposed acquisition of an ideal smelter site in Washoe county, Nevada. It is said that 800 acres of land already have been bought and that construction work will start in the near future.

SIERRA COUNTY

(Special Correspondence.)—The second payment was made this week on the Independence mine, at Alleghany. The property is being operated by San Francisco capitalists. The vein shows strength as developments progress. Fred A. Pearson is manager. The Neocene Mining Co. recently received a shipment of 300 tons of cement, to be used in constructing a new restraining dam at the Scales hydraulic mines. Gravel of good grade has been recently uncovered, and the management has not decided whether to operate the deposit by means of giants, or by drift mining. The necessity of constructing another restraining dam is the costly obstacle to the employment of another giant. Los Angeles people are chiefly interested. The Brandy City M. Co. is operating six monitors at its hydraulic property, in the old Brandy City district. The channel lies between Slate and Canyon creeks, and ranges from 200 to 600 ft. wide. At the present workings the depth is about 200 ft. The strata are exceedingly hard, necessitating blasting, for which black powder is employed. The restraining barrier is a gravel and cement dam, 20 ft. thick. The line of sluices exceeds 1½ miles. This property is understood to be the largest active hydraulic mine in central California, and was reopened after lying idle for nearly 20 years. The company has its own electric-power plant. San Francisco people holding a bond on the Omega have ordered the immediate construction of a six-drill compressor. The electric separating process is used.

Downieville, August 11.

SISKIYOU COUNTY

(Special Correspondence.)—The Siskiyou Syndicate has started a lower adit to open the orebodies on the Cub Bear mine. The adit is about 30 ft. on the vein, with good progress being made. About 65 tons of ore, valued at about $40 per ton, has been extracted and stored. On the surface the 3-ft. vein has been exposed for 100 ft. A cross-cut has passed through 12 ft. of mineralized rock that prospects well. The Cub Bear is in the Russian Creek district, traversed by the Salmon river. Rich quartz is coming from the Homestake, where a narrow shoot of high-grade ore has been opened from the surface to No. 3 adit. This property was recently acquired by R. S. Taylor. John Boyle is superintendent. It is reported that rich ore is being developed in the Highland mine, recently acquired by a Dutch syndicate. This property is the most famous high-grade producer in the county. The Siskiyou Coal Co. is pushing vigorous work on its deposits near Agen. The drills are proving the field quite extensive, and samples of the material are pronounced of commercial grade.

Etna, August 11.

YUBA COUNTY

The Yuba Consolidated Gold Fields, in the year ended February 28, 1911, handled 13,970,728 cu. yd., yielding $2,927,246, which, together with its miscellaneous revenue, brought its total gross earnings up to $2,998,708, and of this amount the net profit was $2,181,336, all but $200,000 of this being paid out in dividends. The average cost per yard was 10.7 cents.

COLORADO

CLEAR CREEK COUNTY

(Special Correspondence.)—The Dives-Pelican and Seven-Thirty M. & M. Co. will construct an aerial tramway from the dumps of the Zero mine to the Pelican mill which from now on will be operated on company account, the leasing company having surrendered its privilege. Work was resumed this week on the North Star property in East Argentine. M. Bonham is owner. H. M. Vincent, owner of the Revelle property, has resumed operations. Holcombe & Co., leasing on the Seven-Thirty mine, are shipping ore that mills 160 to 490 oz. silver per ton. The streak is 10 in. wide. A shipment of 16 tons of smelting ore from the Eade lease on the Capital mine brought a net settlement of $1150. The orebody is from 14 to 18 in. wide. A vein of galena 20 ft. wide has been found in the breast of the adit on the Paragon vein in West Argentine that mills 65% lead and 42 oz. silver per ton. Wm. Coggswell is owner.

Georgetown, August 10.

SAN MIGUEL COUNTY

The survey for the surface trolley from the Ophir adit to the Tomboy mine has been completed. The line will be about a mile long and will be used for conveying ore from the Revenue property, recently purchased by the Tomboy, to a tunnel which will be driven to the 1750-ft. level on the latter property. The ore will be hoisted through the Colorado shaft and crushed at the Tomboy mill.

TELLER COUNTY

An attempt to accelerate the drainage of Cripple Creek mines by constructing two more laterals from the Roosevelt drainage tunnel will be made, according to F. L. Sigel. The laterals will be about 120 ft. long, and it is believed they will cut known watercourses. The water at present is receding at the rate of about 7 ft. per month, and the tunnel is delivering about 5800 gallons per minute.

Press reports state that Miller & Co., lessees, while working on the 300-ft. level of the Stratton's Independence mine, discovered ore assaying 14 oz. gold per ton in one case and 22 oz. gold per ton with a second sample. Philip Argall is manager for the company.

IDAHO

IDAHO COUNTY

The Elk City reduction plant is to be ready for ore-treatment by September 1. A large quantity of concentrate in that district will keep the concentrating-plant busy for some time. The plant will be operated next week, according to the announcements.

SHOSHONE COUNTY

Oscar B. Wallace has resigned the management of the Interstate Silver-Lead M. Co. in order that he may give his entire attention to the Ruth M. & M. Co., in which he is heavily interested. Jack Feeley, formerly of Boulder, is the new manager for the Interstate company.

The Bullion M. Co. has let a contract for the construction of a flume for water-power purposes. The wagon-road from the mine to the railroad has been completed. James H. Taylor, of Wallace, is manager for the company.

The Argenta M. Co. has had its claims surveyed for patent and holds a receipt for patent pending. Since the last report, in January, the adit has been driven 150 ft., making a total of 420 ft. It is rumored that soon equipment will be secured. E. Lindsly is manager.

MICHIGAN

HOUGHTON COUNTY

If a quorum is obtainable, the directors of the Quincy M. Co. will meet soon in Boston to take action on the regular quarterly dividend of $1 due in September. In addition to the $440,000 required annually for dividends, the company has an annual charge for additional territory secured from the St. Mary's Land Co. Reports state that with a $10\frac{1}{2}$c. cost and the market close to $12\frac{1}{2}$c., the company's margin of profit on 22,000,000 lb. of copper per year has not been much larger than dividend requirements.

MONTANA

Lincoln County

(Special Correspondence.)—The Kalispell-Lincoln M. Co., acording to officers of the corporation, has made arrangements to work two shifts of men on the company's property in the West Fisher gold district. It is the intention to put in a stamp-mill soon. The ore is free-milling gold and the vein is 3 ft. wide, with a pay-streak through it which averages 14 in. in width and which is said to assay $100 to the ton. J. J. Hibbard, of Libby, is manager for the company.

Libby, August 13.

NEVADA

Churchill County

(Special Correspondence.)—The 100-ton mill of the Nevada Wonder M. Co., at Wonder, began operation on August 1. A five days' test run was made in June for the purpose of aligning the shafting and testing the mechanical operation of the mill, and since that time such changes as were shown to be necessary have been made, so that now the mill is in good operating order.

The ore is trammed from the mine in side-dumping, 3-ton ore-cars, and dumped into a 200-ton bin. It is then crushed through a Blake crusher and elevated into a 100-ton battery-bin. Thence it goes through a battery of ten 1400-lb. stamps, through a Chilean mill, and a tube-mill. From the grinding department it passes through a Dorr classifier into collecting-tanks and through the usual arrangement of thickeners and agitators, and finally passes through Oliver filters. Zinc-box precipitation is used. The refinery is equipped with Faber du Faur tilting-furnaces. The mill is furnished with Callow cones and Deister concentrating-tables, but at present these are not being used, as the ore is all-slimed and satisfactory results are being obtained without them. So far, the mill gives promise of high percentage of extraction; the tailing going out contains from 50c. to $1 per ton. No clean-up has been made. Water is amply supplied through 10 miles of 4-in. pipe from Horse creek, which heads in Mount Grant. The 100,000-gal. storage-tank above the mill is constantly overflowing.

Development at the mine has been pushed rapidly since May. Sullivan $2\frac{1}{4}$-in. drills and Waugh stopers have been in use since July 12, and over 200 ft. of work per week is being done. Ore for the mill is being furnished both from the development faces and from stopes. The mine machinery equipment consists of a Leyner hoist, a Laidlaw-Dunn-Gordon compressor, and a Sturtevant blower, all operated by electric power; a Leyner drill sharpener and automatic ore-gates from the mine-bins are operated by compressed air. J. A. Burgess, formerly of Tonopah, is superintendent.

Wonder, August 14.

Esmeralda County

A new shaft is to be sunk on the Quartzite No. 1 claim of the Goldfield Belmont M. Co. The shaft, it is announced, will be a deep one, and the means for extensive exploration. It is stated no more leasing will be done.

It is reported that Goldfield Con. during July reduced its cost of production as compared with June, to $7.50, as against $8.06. The record figure, for January, is $7.29. During recent months the poorer grade of ore mined has necessitated an increase in the tonnage of ore treated. On July 31 nine months of the company's fiscal year were completed, and reports show earnings well in excess of dividend requirements.

Humboldt County

Press reports state that Gordon Campbell, one of the pioneer operators in the National district, is arranging a merger of the Consolidated, north of the National mine, the First National, the Mammoth, and White Rocks groups, and possibly other properties. His plans include the organization of a company capitalized at $15,000,000.

Lincoln County

Deeds have been filed conveying the properties formerly owned by the Con. Pioche M. Co. and the Nevada-Utah M. & S. corporation to the Amalgamated Pioche Mines & Smelters corporation. The details of the transfer have been published. A trust deed also was filed from the last corporation to the Paterson Safe Deposit & Trust Co. of Paterson, N. J., as security for the payment of $500,000 of 10-year 6% interest-bearing gold bonds. Work was started at No. 1 shaft August 5.

Nye County

A solid low-grade quartz vein has been found on the Stone Cabin claim of the Jim Butler group near the 600-ft. level of the Stone Cabin shaft. The best ore is found in the transverse fractures of the vein.

The Tonopah-Belmont's gross production for July was valued at $278,107.07, or nearly $5000 more than the June production, according to press reports. During the month, 6883 dry tons was sent to the mill and 2285 dry tons to the smelters, making a total of 9168 tons forwarded. The gold bullion produced amounted to 3931.428 oz., and the silver bullion to 395,868.71 oz. The net profit for the month was $149,170.27. The last figure implies an addition to the reserve fund, as the regular quarterly dividend of 25c. requires monthly earnings of $125,000. The company is reported to have in its treasury already over half a million dollars beyond what will be needed for its next dividend.

The report of the Tonopah M. Co. for July shows a net profit of $120,415. During the month 14,118 dry tons of ore with an average value of $18.89 per ton was sent to the mill. The gold and silver bullion shipped amounted to 256,587 oz. and was valued at $189,765. The concentrate shipments amounted to 113 tons and were valued at $47,860.

At the Montana-Tonopah, 55 bars of bullion, weighing in the aggregate 3629 lb., and 79 tons of concentrate were shipped during July. The production was far in excess of that for June. In the first week of August, 186 ft. of development work was done. Stoping in the numerous levels continues. In the 765-ft. level cutting-out work has been started preparatory to driving drifts on some of the veins, which, intersected at that level, show promising ore.

Tonopah Extension reports show an average for the first week in August of 140 tons of ore milled per day.

The management of the Buckeye-Tonopah, after the recent fire, replaced four sets of timbers at the top of the shaft, although only the collar set, and two other sets were damaged. The newly timbered top is started for a double-compartment working shaft and manway. The surface will be prepared for the new steel head-frame, and pending its arrival a temporary wooden frame will be used.

The Buckeye Eagle mine has received a complete equipment, valued between $6000 and $7000. The equipment consists of a large Leyner hoist with a drum capacity of 1800 ft. of cable; a 52-hp. G. E. motor, geared to hoist, with controller, switches, etc.; and three transformers, together with two Truax ore-cars, buckets, steel cable, and sheave-wheel.

Work has been suspended in the old raise and stope from the 950-ft. level of the North Star, and a new raise has been started nearer the shaft.

NEW MEXICO

Grant County

It is announced that by the end of this month or early in September the Chino Copper Co. will be treating ore at its new mill. By October 1, it is believed, two sections will be in operation, each treating about 1000 tons per day. Stripping at the mine has progressed in a satisfactory manner. A good body of ore, according to report, is being developed southwest of the Hearst mine.

(Special Correspondence.)—John M. Sully, manager for the Chino Copper Co., and G. C. Bowles and C. F. Bruff, construction engineers for the Utah Copper, Ray, and Chino companies, had an exciting experience at the hands of bandits on August 10. On their way, by auto, to Hurley they were stopped by three masked men between Bayard station and Hurley, through an erroneous report that the mining men were carrying pay-roll money for the latter place. Sitting in the tonneau, the bandits forced the autoists to undertake an impromptu 'elimination run' by turning out of the road into rough country. After the machine had been stuck in a sand arroyo, the road agents relieved the men of their valuables and also the spark plug of the automobile. The men walked to Hurley. The bandits later 'got the drop' on the sheriff's posse in Martin's canyon and took the horses and guns. As yet the robbers have not been captured.

Santa Rita, August 12.

SOCORRO COUNTY

(Special Correspondence.)—The Ernestine Mining Co.'s mill treated 1410 tons of ore in the past two weeks. The last two clean-ups for July yielded 13,094 oz. gold and silver bullion and 20,000 lb. of high-grade concentrate. Grading for the new power-plant has been started, the construction being under the direct supervision of one of the leading engineers of the West. Sixty tons per day is being mined and teamed to the Treasure Mining & Reduction Co.'s mill. All machinery in both mine and mill is operated by electricity generated by water-power on Whitewater creek, at a total cost of less than $10 per day. This is at the rate of $18 per horse-power year. Bids are being obtained for the construction of a wire-rope tramway from mine to mill which will admit crushing 40,000 tons of dump ore at a good profit. New ore-zones are being discovered in the mine under the intelligent work of the foreman, and the property will be capable of producing a much larger tonnage.

At the Socorro Mines 5300 tons was milled during the month of July, producing 33,400 oz. gold and silver bullion and 21,000 lb. of concentrate. Concentrate from this mill yields about $2000 per ton. The usual good extraction of 93% is being maintained, and the developments throughout the mine are satisfactory. Good progress was made by the Oaks Co. in the main drainage and transportation tunnel during the week. Development work continues in the Little Charlie tunnel of the Mogollon Gold & Copper Co. which is yielding a high-grade average mill-ore, from which much shipping ore is being assorted. Work continues in the new shaft of the Maud Mining Co. as heretofore.

Mogollon, August 11.

SOUTH DAKOTA

LAWRENCE COUNTY

Wasp No. 2 paid its regular dividend of one cent per share, and an extra dividend of the same amount, during July. Mining costs are being reduced somewhat, and the mill kept running at capacity, 480 tons per day. John Gray, general manager, has left for Europe to spend the summer.

UTAH

BEAVER COUNTY

The South Utah Mines & Smelter Co. in July produced 254,462 lb. of copper, 2096 oz. of silver, and 106 oz. of gold. Over 19,500 tons of ore averaging 1.21% copper and yielding 1750 tons of concentrate was received at the mill. The concentrate averaged 8.07% copper.

SALT LAKE COUNTY

At the annual meeting of the Cardiff M. & M. Co., August 11, it was announced that the company had on hand, July 11, $3771.63. On August 31, 1910, the company had on hand $1744.71; two assessments brought $5001.77, and ore-sales returned $24,876.82 net. Of this total of $31,623.30, $27,851.67 was paid out by check. The ore-receipts specified were between the latter part of July 1910 and January 18, 1911, and were from the sale of 632½ tons. Ezra Thompson, president, has stated that work soon will be started on the new adit to connect with the bottom workings which will give 600 ft. vertical depth. Ore is reported to be marketed at the rate of 100 tons per month.

WASHINGTON

FERRY COUNTY

(Special Correspondence.)—At the Knob Hill mine the raise from the No. 4 level is up 105 ft., the last 5 ft. being in ore that has a shipping value reported better than $60 per ton. On the No. 2 level, 68 ft. above, the same pay-shoot has been followed 220 linear feet. At the San Poil Con., the North San Poil raise has holed through into the shaft. In stoping at the south end of the pay-shoot 3 ft. in width, and going northward from 2 to 4 ft. in width, the ore assays from $15 to $20 per ton. The north drift has only 30 ft. to run to the end line, and after driving that distance the drills will be removed to the end of the south drift on the No. 4 level. Last week four carloads of ore was shipped to the smelter, and the same quantity has already been shipped this week. The smelter returns are now running from $27 to $30 per ton. At 120 ft. north of the raise, on the No. 2 level, two rounds of holes have started a new stope from 4 to 6 ft. wide, and the ore assays from $12 to $20 per ton.

The Illinois M. Co., in Keller district, has installed a 25-hp. gasoline engine, an air-compressor and receiver, a Wood's 2½-in. drill, and 600 ft. of pipe, and is resuming operations at the mine. The Rebekah M. Co. has five claims on the south half of the Colville Indian reservation, covering about 3500 ft. of a copper-bearing vein. The ore assays about $28 per ton.

Republic, August 12.

SPOKANE COUNTY

United States Smelting, Refining & Mining Co., which operates custom plants in Mexico, California, Utah, and other States, has taken out a license in Washington and appointed A. C. Barke, formerly connected with the smelter at Northport, Wash., as its representative. The company also has agents in the Coeur d'Alene and Nelson districts. Arrangements are being made to secure the Canadian output of lead in the event the duty is taken off.

CANADA

BRITISH COLUMBIA

Stockholders of the Island S. & R. Co., the $10,000,000 corporation organized by Donald D. Mann, have authorized the construction of a testing plant for the treatment of lead, zinc, and other refractory ores in British Columbia. Mr. Mann shortly will visit Stewart with several mining experts.

At the International mine, work has been started on the main working-adit at a depth of 700 ft. from the upper showings. A second prospect-adit is being driven at 500 ft. Indications are promising. Roy Clothier is in charge.

Albert Lund, owner, with Joseph Rogers, of the Mamie and Bessie claims, above the Bear River M. Co.'s property, reports a large copper-gold ore deposit there, of which recent samples assayed as high as 35% copper and $2.50 gold per ton.

The British Columbia Copper Co. in June produced 816,676 lb. of copper, making a total of 5,144,365 lb. for the six months ended June 30, against 2,978,227 for the same period last year. In June 11,472 oz. silver and 2428 oz. gold were produced.

Charles Camsell, of the Dominion Geological Survey, recently stated at Hope that his surveys near Steamboat mountain resulted in finding only evidence of coal beds. He laughed at the idea of finding gold there.

Press reports state rich-looking ore has been found in the cliffs of Coquahalla valley.

The annual report of the Granby Con. M. S. & P. Co. for the fiscal year ended June 30, shows that the production for the year was the smallest since 1906. Assuming a copper cost of 10¾c. per pound and a selling price of 12.33c., the net income from the 17,795,215 lb. of copper produced was about $282,000. In the fiscal year ended June 30, 1910, it cost the company 10.3c. per pound to produce about 22,000,000 lb. of copper. The higher cost this year was due to a temporary shut-down of the smelter, a decline in ore content, and higher fuel charges. The estimate of earnings does not include several 1% dividends on its holdings of the Crow's Nest Pass Coal Co. In the year, Granby Con. paid one dividend of $1 on its 148,495 shares. Since the payment, 1500 shares of treasury stock were issued as part payment for new property, making 149,995 outstanding shares. The smelter was enlarged some months ago and has eight furnaces.

GRANBY SMELTER.

Discovery of platinum near Slocan Junction has resulted in a rush of locators to the Kootenai river, where a syndicate, headed by Alfred Jeffs, has staked 14 claims on the dike. The assays from samples range in value from $72 to $176 per ton. The extent to which claims are being located will be understood when it is known that one prospector staked a claim which included the city power-plant at Nelson. Ranchers in the district are defending their holdings against invaders.

CHILE

O'Higgins

The first 1000-ton unit of the 3000-ton concentrator of the Braden Copper Co. has practically been completed, and cable reports of its being placed in commission are expected daily, states Pope Yeatman, consulting engineer for the company. One of the generators at the company's hydro-electric station is in position, but has not been adjusted. The first part in commission will represent 6000 kw. Most of the important development has been at the Fortuna mine, but work is now being pushed at the Tiente mine, where sulphides assaying 4% copper have been found in large quantity. It is believed that the orebodies at Braden are of primary origin, and hence persistent in depth.

GUATEMALA

The executive mining concession granted the Guatemala M. & D. Co. has been approved by the national assembly, states R. S. Reynolds Hitt, American Minister at Guatamala City. Archibald E. Spriggs, as representative of the company, is the original grantee. The company has exploring parties, one of over 50 men, already in the field.

MEXICO

Chihuahua

The Estella M. Co. is putting down a 2-compartment shaft and, if favorable indications are shown, cross-cutting and driving will be done. The threatened labor trouble at the Santa Eulalia will not affect the Estella, according to W. F. Swoyer, manager of the latter mine. A large amount of capital was invested by London men in the Santa Eulalia during the recent rebellion. Development work is being pushed at the Sierra Mojina. In regard to the last, Mr. Swoyer stated in an interview: "The present management intends operating on a large scale in the near future, putting in economical devices for extracting the ore and facilitating transportation to Gallego." Mr. Swoyer is in the office of the Estella M. Co., Calle Victorria 319, Chihuahua.

Jalisco

Machinery for the Mirador M. Co. is being received at Magdalena, shipping station for the Hostotipaquillo district, and is being forwarded as fast as possible to the proposed site, according to press despatches. The plant, which will occupy part of the El Favor M. Co.'s mill-building, will consist of 15 stamps, concentrators, tube-mills, and a cyanide equipment. The Mirador and El Favor properties, which are close together, are controlled by the Makeever brothers of New York.

Two adits are being driven on the Mina Grande property, Hostotipaquillo district, to cut the veins of the Mina Grande below the old workings. The company recently made a shipment of ore from the old workings of the Juarez mine to the San Luis Potosi smelter which averaged 6500 gm. per ton, according to newspaper report. W. A. Hoeing, of Guadalajara, is general manager for the company.

Oaxaca

Steel timber-sets are being placed throughout the Los Ocotes property in the Ejutla district, according to Associated Press despatches in Mexican papers, and the main shaft is being enlarged to two compartments. It is the property of the Teziutlan Copper M. & S. Co. Denouncing of claims in Oaxaca camps was more general during the recent insurrection period than at any other time in the past two years. Mining conditions have not greatly suffered, and there has been little trouble from strikes.

The San Jose mill and mine in the Dierra Juarez district have resumed operations after being shut down for nearly a year. Charles Davenport is in charge.

A. W. Hollenborg is resuming development work on the Cajones silver properties, owned by Louisville, Ky., men. The ore is found in extensive flat veins rich in sulphides. Transportation facilities are poor, but water-power and fuel are available, and ultimately, it is reported, a treatment plant will be built.

Parral

A new pumping outfit is to be placed in the near future on the Esmeralda property, where a remarkably rich vein, according to report, was found a short while ago. Wade Armstrong is manager of the mine.

Sonora

The two new electrically-controlled converter stands being placed in the Greene-Cananea smelter will enable the company to increase its output heavily. The stands will be of the same pattern as those now in use.

Greene-Cananea made its largest monthly production of the past year in July, 3,994,000 lb. of copper. The silver yield was 112,921 oz., the second largest this year, and the gold extraction of 582 oz. is exceeded in the company's history only by the output of April 1909, 611 oz. In March this year the copper production was 4,000,000 pounds.

The Mina Mexico smelter, near Toiuchi, has been closed down, as heavy rains have interfered with the transportation of supplies.

The Guaymas smelter of the Pacific S. & M. Co. will soon be blown in. Courtenay De Kalb, general manager for the company, has stated that he is in the market for ore.

George W. DuBes, owner of the San Jose mine, near Alamos, has bought a steam-hoist, compressor, and air-drill, which soon will be put in place on the property.

The Padre Hoben M. Co. soon will start work on the property near Chinipas. The mine was purchased from Father Hoben of Pecos, Texas. The purchasers are Battle Creek, Mich., investors.

URUGUAY

A New Jersey oil company has entered the Republic, states F. W. Goding, consul at Montevideo. A system of depots will be established and a refinery will be built either at Montevideo or Buenos Aires. American enterprise gradually is entering that part of the continent.

Decisions Relating to Mining

Specially reported for the Mining and Scientific Press

Injury to Miner—Questions for the Jury

The question as to whether the particular condition created by a loose rock and the successive explosions of dynamite rendered the place unsafe, and whether ordinary care required that the rock be removed or supported in place, and whether or not, if it was negligence to leave the rock in place, it was the negligence of the defendant, and whether or not it was contributory negligence on the part of the plaintiff to continue work in such apparent danger, are all questions of fact for the jury to determine.

Lewis v. Detroit Vitrified Brick Co., (Michigan) 129 Northwestern, 726. Feb. 1911.

Pollution of Water by Mining Company

The sale to a mining company of the right to mine coal under the grantor's land does not give the company the right of polluting a watercourse on such land by copperas and slack from the mine. And it cannot avoid liability for injuring land for agricultural purposes by reason of placing the slack and copperas in a watercourse, by showing that the mine was operated in a careful and prudent manner. Neither is it a defense to an action for such damages that the land-owner did not object to the opening of the mine.

Nebo Consolidated Coal & Coking Co. v. Lynch, (Kentucky) 133 Southwestern, 763. Jan. 1911.

Construction of Mining Lease

Where a lessee agrees to pay the lessor a royalty depending upon the amount of minerals mined, he thereby impliedly obligates himself to begin developing within a reasonable time and to continue the same. And where the lessee convenants to prospect the land and in case he discovers minerals to pay the lessor a stipulated royalty on the ore mined, such covenant to prospect is in the nature of a condition and the lessee must proceed with and persist in prospecting with reasonable diligence and continuity of effort. And a suspension of prospecting operations for a period of 14 months justifies the finding that the delay was unreasonable.

Loveland v. Longheury, (Wisconsin) 129 Northwestern, 650. Jan. 1911.

Employment of Minor in Coal Mine—Negligence

The statute of West Virginia provides that no boy under 14 years of age shall be employed or shall be permitted to work in any coal mine. But the statute is not construed to mean that an employer shall respond in damages for all injuries sustained by such a boy though employed in a coal mine. While such a boy may have a civil remedy for an injury sustained in such unlawful employment and resort to the violation of the statute for evidence of the negligence which caused the injury, still the statute does not imply that the employer shall respond in damages other than those given by the common law. It does not impose an absolute liability for civil damages, but it may be shown that the employer is liable for damages at the common law for injuries sustained by reason of the violation of the statute; neither can it be said as a matter of law that such an employer is chargeable in damages with the injuries that result. "The true question to be determined," say the Supreme Court of West Virginia, "in an action based upon a failure to obey a statute like the one in consideration, is: Did the unlawful employment cause the injury? The trial of the case must be guided by this question. If the injury complained of is a natural and probable consequence of a violation of the statute, then that violation is correctly taken as the proximate cause of the injury. If the very injury has happened which was intended to be prevented by the statute law, that injury must be considered as directly caused by the non-observance of the law. But if the injury is one that happened by causes independent of the violation of the statute, it is not actionable on the basis of that violation. If the intervening event against which the statute evidently did not intend to provide, and the appearance of which was not anticipated by the spirit and purpose of the act, has in fact caused the injury, that event is plainly the proximate cause."

Norman v. Virginia Pocahontas Coal Co., (West Virginia) 69 Southeastern, 857. Dec. 1910.

Personal

Professional men are invited to send news of their engagements and travels. Such news is interesting to friends.

H. C. Callahan is in London.

C. E. Singer is at Pueblo, Colorado.

D. C. Jackling was in San Francisco.

V. B. Sherrod is at Goldroad, Arizona.

N. S. Kelsey is at Jackson, California.

Charles Janin is resting at Lake Tahoe.

J. C. Nichols has gone to San Salvador.

C. W. Merrill has returned from the East.

Hennen Jennings has been in San Francisco.

Howard D. Smith has returned to San Francisco.

Albert Burch is expected in San Francisco today.

M. H. Kuryla is at San Sebastian, Jalisco, Mexico.

G. F. Beardsley has gone to Monterey county, California.

S. H. Ball has left New York for the west coast of Mexico.

A. K. McDaniel was in San Francisco and has gone to Cananea.

James G. Berryhill and W. C. Orem have been in San Francisco.

Richard B. Stanford arrived in New York on August 7 from London.

Atholl F. McEwen has gone to British Central Africa by way of London.

W. E. Defty has moved from Long Beach, California, to Phoenix, Arizona.

E. E. Carpenter is with the Nevada Hills Mining Co., at Fairview, Nevada.

Dana A. Langley is at Clifton, Arizona, having left Mogollon, New Mexico.

W. A. Barrington, of Mexico, will be in Kansas for the next three months.

Courtenay De Kalb has been in San Francisco and has gone to Tucson, Arizona.

A. P. Dumas is with the Mina la Cruz y Anexas, at Zimapan, Hidalgo, Mexico.

S. E. Bretherton is in Plumas county, California, examining land for gold-dredging purposes.

Wm. J. Priestley, Jr., is superintendent and mine manager for the Fairbanks Alaska Exploration Company.

Ralph Arnold has returned to California from London, having come by way of Trinidad, South America.

T. M. Hamilton is superintendent for the American Smelting & Refining Co., at Charcas, San Luis Potosi, Mexico.

L. W. Bahney has been elected to the chair of metallurgy in the Sheffield Scientific School, New Haven, Connecticut.

Harry J. Wolf has lately been appointed manager, for the lessees, of the Stanley Mines Co.'s properties at Idaho Springs, Colorado.

Commercial Paragraphs

GEORGE H. GARREY, formerly of the U. S. Geological Survey, and formerly mining geologist with the A. S. & R. Co., the American Smelters Securities Co., and Guggenheim Exploration Co., and recently manager of the southern division of Spurr & Cox., Inc., has just opened an office as consulting geologist in the Crocker building, San Francisco. Mr. Garrey will continue to act for Spurr & Co., handling their San Francisco business.

At a meeting of the Board of Directors of the WESTINGHOUSE ELECTRIC & MANUFACTURING COMPANY, held in New York on August 1, the following officers were elected: Chairman of the Board of Directors, Robert Mather; President, Edwin M. Herr; Vice-Presidents, Loyall A. Osborne, Chas. A. Terry, Harry P. Davis; Acting Vice-Presidents, Henry D. Shute, George P. Hebard; Comptroller and Secretary, James C. Bennett; Treasurer, T. W. Siemon; Auditor, F. E. Craig. E. M. Herr is elected to succeed Edwin F. Atkins, who has been president of the company since June 1910, and who declined re-election. Mr. Herr has been First Vice-President of the company since 1905. He has announced the appointment of Calvert Townley as assistant to the president.

'Step' Concentrator Belt

The Goodyear Rubber Co., San Francisco and Portland, Oregon, is meeting with success in the sale of its 'step' concentrator belt. The surface of this belt is composed of a series of transverse steps with 'treads' ¼ in. wide and 'risers' 1/32 in. high. When the belt is running on a concentrator the 'treads' are horizontal. The heavy particles of mineral are held on each step and gradually travel toward the mineral-discharge end of the machine. This belt is well worth investigation. Other products of the Goodyear Rubber Co. are dredging sleeves, hose, packing, belting, crack-proof miners' boots, ponchos, and oiled clothing of all kinds.

EDITORIAL

SANTA EULALIA, in Chihuahua, has been interestingly compared to Leadville, in Colorado, and, indeed, there are many points of resemblance in the ore deposits of the two districts. Recently a company has been formed to develop deep levels in that part of the Mexican district which corresponds to the 'down town' part of Leadville.

OUTLOOK for higher prices for silver is not encouraging. It had been expected that before this time the Indian Government would have resumed purchases of the metal. Crop conditions, however, have been bad. A drought has made famine measures necessary over half the country, and there has been an unfavorable planting season. As a result the natives are drawing on rather than adding to their buried hoards.

PLANS for the meeting of the American Institute of Mining Engineers in San Francisco in October indicate that the sessions will be of unusual interest. Mr. F. W. Bradley, chairman of the sub-committee in charge of the matter, is arranging for one session devoted exclusively to improvements in cyanidation. Probably others will be similarly devoted to special topics. It is well that attention be not concentrated too exclusively on excursions, delightful and profitable as they always are. The Institute is primarily for technical work and workers.

PHILIPPINE gold mining has not made the rapid advance that was at one time anticipated. For this condition there are many reasons. Those which apply to dredging are discussed lucidly on another page by Mr. R. Y. Hanlon, whose experience in examining placers and whose knowledge of the Far East give especial emphasis to what he writes. Apparently placers of real value occur. Their extent is largely unknown, and there are difficulties, though not insurmountable ones, in the way of their development. Handling large dredges in a tidal estuary none too well protected from storms, and digging swampy wood-filled gravel, is not easy. Ground, however, that contains 25 to 60 cents per yard in gold, permits incurring considerable expenditure and warrants careful investigation.

ZINC ore prices have gone up at Joplin owing to temporary shortage of supply. For the week ending August 12 the basis price for 60 per cent blende rose from $42 to $45, and $47 per ton was paid for premium grades. Flooding of the mines caused the shortage, but by September 1 conditions should be normal. For the first 32 weeks of this year the total sales of blende have amounted to 332,078,300 pounds and of galena 54,374,630. The total value is estimated at $7,891,543. Zinc is in much better position in many ways than is copper. That everyone is working on a narrow basis is shown by the fact that temporary flooding of mines at Joplin raised the price of ore $3 per ton. The surplus of spelter that was on hand at the beginning of the year is understood to have been absorbed, and there is now an active demand both for ore and metal. In the meantime new plants have not been built as rapidly as the gas plants in Kansas have gone out of commission. The American Zinc, Lead & Smelting Company has plans under way for a coal-burning smelter in Illinois, and doubtless other plants will follow. As to ore supply, the most important recent move has been the entry of some of the big companies into the Tennessee field. It has long been known that East Tennessee includes large areas of zinc-bearing territory. The ore, it is true, is of low grade, but with operations conducted on a large scale, and with present prices, there is an opportunity for profitable business.

CHINESE workmen in the furniture factories in Victoria have organized a union and adopted union methods of restricting work to their own members, according to *The Australian Mining Standard.* The Chinese guilds are well known in the East, and the only surprising thing is that retaliation has not sooner been attempted. The ideal of 'A White Australia' rests on good grounds, but, as the *Standard* points out, its advocates have in many particulars taken unwise methods to realize it. A Chinese labor union may sound funny at first, but is really a serious matter.

OAKLAND, California, is living over a gas well, according to the enthusiastic statements of the Oakland Natural Gas Company, which corporation proposes "forcing the earth to disgorge its hidden treasure." Fine sentiment, that! It would be truly a hard old world that would refuse so determined an assault. It seems that the secret of the earth has been discovered by Mr. C. L. Cofer, who is described as a "vegetable scientist" and who, by means of his "Terrestrial Wave Detector" has determined that "there is unlimited gas within easy distance of Oakland." There may be. We do not know. But neither, we believe, does Mr. Cofer.

AMERICAN CONSERVATION, the official organ of the National Conservation Association, has suspended publication—"not because it has failed to meet the expectations of its founders, for it has not failed—but because it absorbs time and energy needed for the practical constructive work of the National Conservation Association." The officers of the latter feel that the need of the present is less that for active propaganda and more for constructive legislation. It marks a distinct epoch when the leaders of the movement announce that "We have passed the time when to continue agitating along the old lines is either necessary or desirable."

LEADERSHIP is discussed informingly by Mr. Woodrow Wilson in a recent interview in *Harper's Weekly.* It is always interesting to know how a man who does a thing especially well, looks at his work, and Mr. Wilson has shown unusual qualities as a leader. His own notion is that the real leader is not the man who impresses his own wishes and views on others, but rather he who rightly hears and rightly interprets the finest and best public opinion. He gathers the general inspiration and brings it to a focus. "It is something like what Bagehot says of Sir Robert Peel: 'It was not that he did extraordinary things, but that he did ordinary things extraordinarily well. He is the true leader who interprets the general conscience rightly, and rightly makes it operative.'"

CHINA must adopt modern methods in Manchuria if she wishes that province to develop as have the Western nations. In some cases, particularly in the interior, superstitions have prevented mining in China, but such is not the case in Manchuria. The people in Manchuria are free from many of the prejudices of those living in other parts of China. The system of concessions has failed to develop China's mineral resources to any marked extent, and it would seem desirable to adopt a claim system in Manchuria, such as is used by Western nations. As is recommended by the *National Review*, published at Shanghai, registration of companies should be made possible only at Peking, and Chinese jurisdiction should be admitted in articles of association. In this way China might succeed where Japan has virtually failed, and develop her vast mineral resources.

OCCASIONALLY something is said about geologists being impractical, and, in particular, there has been quiet comment upon their activity in examining and reporting upon oilfields. There is some point to the criticism, but by way of maintaining equilibrium, we quote below from a report made by a 'practical' man and seriously put forward as a basis for investment: "The contour shows a series of undulating hills, with a number of low precipitous bluffs. There is exposed to view two distinct and intact anticlines and all kind of shale, such as chico fossil, pelecypoda fossil, gasteropoda fossil, etchgon fossil, echinodernate fossil, vaqueros fossil, jacatalitoss fossil, tulors fossil, the black shale and red sand strata, which does appear at the right time and place, is the most positive indication for petroleum oil of high gravity; and extraordinary as it may seem, no true synclinal depressions or subsidence appear in center of oil belt formation, being intact along its original flow of bedding. * * * The geological age of the formation exposed ranges from the cretaceous to the jurassic trassic carboniferous. Permian and upper devonian of the high points; the calaceous is mostly in evidence in the foothills near the outcrop or apex. Jurassic form the chief exposure along and adjoining the Southeast and Northwest portion of the oil belt. The exoding of the indications of oil are so exposed that it makes this field a positive one as to results and not one-fourth of one per cent of a gamble. I judge from the indications and practical drilling in the State of California, as the writer drilled the first oil well in the State. * * * I also examined the water conditions; this I find to be an underground river, which is easily traced."

Japan in the Pacific

In a recent article Mr. Albert B. Hart has taken issue with Mr. R. P. Hobson's fantastic statements upon the present and future relationship between Japan and the United States. Mr. Hobson is undoubtedly a brave man, he is presumably deeply versed in matters of naval technology, but his opinions upon international relationships appear to be of negative value, and Mr. Hart pays them too much deference in devoting so many words to their controversion. Discussing the subject in too much detail often serves only to obscure its most essential features. Mr. Hart has not brought out the really fundamental factors bearing upon the over-discussed topic of a possible war with Japan as clearly as might be desired. Wars are like prize-fights; they are not only unnecessary and brutal, but are also often quite as much a question of 'backers' as of principals. Japan is backed by the large financial houses of Europe that have furnished her huge amounts of capital to carry on the ambitious campaign of industrial expansion that she is now waging. Her backers would no more permit her to divert her energy and resources from industrial work into a futile war with the United States than the backers of a prize-fighter would allow him to stop the battle in order to climb out of the ring and chastise a bystander who, after the manner of the irresponsible sensation-loving part of the daily press in America, had hurled annoying epithets. It must be remembered that Japan is now in a position vitally different from that at the beginning of the Russo-Japanese war. Then her European loans were comparatively small and she was relatively foot free. Now her indebtedness to Europe is enormous. She must keep herself in a position to pay the interest; otherwise, to use a rough but not inaccurate simile, her European bankers will foreclose their mortgages. The financial positions of both China and Japan are precarious. Both are now doing business largely upon borrowed capital. China is a country of large resources, her indebtedness is comparatively small, but her financial system is antiquated and inadequate, and the policies of her rulers are vacillating. Japan's finances are managed with admirable skill, but her resources are small and her indebtedness is great. It is difficult to say which is in the less favorable position.

But what, except childish folly, is there to bring about a war between Japan and the United States? Boiled down to its essential features, it would appear that 'husky' Westerners, who take a pride amounting to affectation in their collarless shirts, corduroy trousers, and dusty high boots, refuse to take seriously the Japanese gentlemen who look upon a silk hat and frock coat with almost religious veneration. Thereby the Westerner offends the Easterner's sense of dignity. On the other side, some Americans feel that since their recent victory the Japanese are 'too fresh' and 'need taking down a peg'. These are the reasons of schoolboys, they do not merit the serious attention of mature minds. There is, however, a vital issue at stake between the two countries. Will the United States allow herself to be euchred out of the position which of right pertains to her, the leadership, not domination, in the Pacific? In the solution of this problem, fiery orations for the benefit of constituents and twelve line 'scareheads' are worse than useless. Attention to the business side of the problem has been too long delayed, but work of signal importance has already been accomplished. The group of American bankers who have been represented in the Far East by Mr. Willard Straight, backed by the firm support of Mr. Henry P. Fletcher, now Minister to Chile, and Mr. William J. Calhoun, the present Minister to China, has played a game of financial strategy with commendable skill and has gone far toward rewinning for America and Americans that measure of respect from the Far East that had previously been frittered away. Now that States are no longer playthings of kings, economic conditions control all deep-seated movements, and leadership belongs to business statesmen rather than to word-spouting alarmists.

Is This Mining?

Frenzied finance is not conducted alone on Wall Street, if we may judge from revelations made in the Spokane County Superior Court of Washington, where Mr. L. E. Collier, receiver for the Naomi Gold Mining Company, has recently filed his report. This company is capitalized at $1,500,000 and exchanged its capital stock with Mr. W. D. Irwin for mining claims in Oregon. Afterward Mr. Irwin transferred 500,000 shares back to the company, which treasury stock was turned over to a Mr. L. L. Ratliff, 'sales manager'. For the sale of this stock the latter was paid 65 cents out of every dollar received, and of the remaining 35 cents, the receiver finds no trace. In the meantime the company accumulated debts to the amount of $4000, in part for doing assessment work.

The story is unusual only in that the details are a matter of court record. Everyone familiar with mining in the West can recall many such cases of reckless company promotion. Stockholders in any business so conducted have only the most infinitesimal chance of recovering their capital, to say nothing of making any profit, yet it is on the basis of participation in some such scheme that many men condemn mining. Most States require that any non-assessable stock shall only be issued when fully paid either in cash or property. In the latter lies the joker. There is no ready and adequate means of determining the value of the property exchanged for the stock. If the two parties to the transaction agree, the law is supposed to be satisfied. As a matter of fact, the buyer and seller are usually one and the same, that is, a man owning a mine or merely a few claims, organizes a company of which he and his friends are to hold control, and transfers the property to the company in exchange for the whole of its capital stock. By this fiction the stock becomes 'fully paid'. There is some question whether, in cases where the estimated value of the property was palpably and greatly exaggerated for the purposes of the transaction, later buyers of the stock do not assume a contingent liability when purchasing it at any price below par. Actually the question is not raised, and this simple device operates regularly to defeat the purpose of the law, which is, to make sure that at the time stock is issued, each share shall be paid out only for cash or property honestly worth the full par value of the share. In the case under consideration, even without detailed information of the property in question, it requires but little knowledge of mining to be sure that the property of the Naomi Gold Mining Company was not worth $1,500,000 at the time it was acquired. Gold mines worth that amount of cash are rare, particularly in Oregon. Furthermore, if the property was honestly worth that much money, there would have been no necessity for paying 65 per cent commission to sell the stock needed for development. Again, any property worth so much real money would hardly be on land requiring assessment work to hold title. All the evidence indicates that unproved prospects, probably not even on patented ground, were sold for '$1,500,000'. There probably never has been such a prospect that was honestly worth that amount of money, whatever it may have become worth later.

In all such promotions the real investor stands no chance whatever. Control is fixed in the hands of men who coolly appropriate two-thirds of any possible returns, and the poor victim pays nearly twice as much as his real investment, to the slick talker who persuades him to part with his money. Generally, also, the promoters sell their own rather than treasury stock until enough money has been realized to fully clear them of even the minor expenses incident to finding a few prospects and organizing a company. Often an examination will show that the title to even such property as is transferred to the company, is imperfect if not actually bad. Many times when old mines or producing properties are promoted, it is not a title, but an option to buy, a bond and lease perhaps, that is acquired by the new company. This fact rarely is stated plainly in the literature or by the agents. It is because such stocks are widely distributed by pertinacious salesmen among people unused to mining, that the industry has acquired an exaggerated reputation for financial risk. If the mining industry is to flourish, capital will have to be raised in large amounts, and, directly or indirectly, this money must come from the accumulated surplus earnings of individuals. The only feasible way of securing the funds necessary for mining, as well as for investment in other industries, is through stock companies. Capital, however, will not steadily flow into an unprofitable or dishonestly managed industry, and mining needs not only improved technical direction, but more honest financial guidance. Laws designed to protect investors more strictly have been adopted in Nevada and other States. Doubtless they will be enacted elsewhere, but above and beyond that there is needed here, as in other walks of life, a higher standard of honesty; a standard that involves obedience to the law, even if cunning lawyers can find a way 'to get around it'. More of the spirit of fair play is demanded.

American Influence on Mining Operations Controlled in Europe

By C. A. Tupper

After a three months trip through all of the principal countries of Europe, west of Russia, I can summarize the situation as one most favorable to the further extension of American influence in methods of mining and ore reduction, and, consequently, in the sale of machinery.

In the treatment of iron ore, the manufacture of coke, steel-making, or the utilization of waste products and gases, the flow of ideas and improvements in equipment has been from Europe to the United States, rather than the reverse; but machinery for mining work in general and for the recovery of metals other than iron from ores has been developed to a greater degree of efficiency in this country than abroad, owing not only to the wider range of American experience, but also to the greater opportunity here for specialization in designing. Hence, the field for American engineering, and the openings for the sale of American mining and metallurgical equipment, are large.

This might not be true if the Continent of Europe, of and by itself, were to be considered; but the investments made by British and Continental capital in mining enterprises the world over, particularly in the colonies or other dependencies of European countries, lead annually to the purchase in London, Paris, Brussels, Berlin, Hamburg, St. Petersburg, Vienna, Prague, Budapest, and other large commercial centres, of much machinery for export. Some of the leading American manufacturers, through branch offices and agencies, are securing a large part of this trade, and a portion of it is even placed directly in this country by representatives of European owners; but there is much more of the business that can be obtained by proper cultivation of the field abroad. Having been given exceptional opportunities of observing conditions, I can state this most emphatically. Moreover, by keeping watch of the experience of European users, at the mines under their control, American manufacturers put themselves not merely in a position to meet the most advanced requirements of such users, but also to learn, in doing so, how many of our own ore-reduction problems can be more effectually solved.

In coal mining, European interest is principally enlisted by electrical operation, cutting machines, better ventilation and dust removal, and the prevention of accidents; in iron mining the use of large breakers, steam-shovels for loading, wet magnetic separation, dryers, and briquetting is foremost; in the recovery of lead, zinc, copper, and tin, the introduction of multi-hearth, mechanically stirred furnaces of large capacity have been given much attention; and in gold and silver mining the various operations attending cyanidation still have more thought devoted to them than any remaining feature of the work. With all of these and other minerals and metals, however, consideration of the problems of concentration is also exceedingly active.

Anyone who can show an improvement in any phase of the cyanide process will find interested auditors on the other side of the Atlantic; but he must be able to demonstrate it by results applicable to the purchaser's conditions, for so many unfounded claims have been made in behalf of American apparatus that Europeans are now chary of accepting any more on faith. Samples of ores from their mines are, however, usually obtainable for tests; and the erection of equipment on approval, where needed, is ordinarily not difficult to bring about. One successful plant in a district under European control will also enable many similar sales to be made, as the work at the various plants is closely followed by the engineers at neighboring properties.

I have mentioned cyanidation first because it holds the leading place, at present, in the thoughts of the mining men abroad, particularly in connection with relatively low-grade ore; but similar opportunities exist in practically all other lines. Machinery of any kind that stands for a better output or shows increased economy in its operation is readily salable to mine owners; and the matter of price cuts far less figure than might be supposed. The German system of computing efficiency has come largely into vogue. More and more, by means of actual working tests, mine owners are figuring carefully just what increases of output or saving in costs may be brought about by contemplated improvements, on the basis of a year's run. The specific opportunities can, perhaps, be best illustrated by reference to the various types of apparatus involved.

In the line of pneumatic tools the manufacturers of the United States are generally conceded a leading place, and American rock-drills predominate. Their sale is being effectually pushed in London, particularly by one company, but more might be done on the Continent. Air-compressors are also salable to a less extent, those adapted to motor drive being most in demand. For both compressors and drills, however, the competition of European manufacturers, from the standpoint of efficiency, has become increasingly strong; and in some recent trial runs American machines seem to have been carefully excluded. For electric firing in blasting operations, European systems have generally given satisfaction.

In the construction of hoists or winding engines American practice has generally fallen behind European. The electric hoist, operated by alternating current motors for the most part, is rapidly displacing steam-driven units, and the arrangements worked out abroad for subjecting the electrical end to variable speed control are superior to the work of all but one or two American designers. The driving motor most successfully used is not the wound-motor induction machine familiar in this country, but a commutator alternating current motor in which speed variation is effected by an automatic shifting of the position of the brushes. British and German over-winding safety devices have also been well developed.

Stamp-mills of well known American types still hold their own. Supremacy in this respect is threatened by the present European tendency to use tough alloy steels, such as vanadium, for the stems, shoes, dies, and other parts subject to heavy strains, shock, or impact; but this will not be for long, as American manufacturers are experimenting along the same lines. For prospector's use the light portable steam-stamp of American design is in a class by itself.

Tube-mills and ball-mills made in the United States come into strong competition with German and Swedish machines, which sell at relatively low prices and are exceedingly durable in all their parts. American ingenuity in the matter of introducing the feed, in tube-mill lining, in the discharge mechanism, and in the arrangement of gearing, counterbalances these advantages to some extent; but it will pay manufacturers to find means of using better material at less cost. By substituting a special alloy metal which could be made thinner and yet considerably tougher than that now employed, a reduction of weight, of the power for driving, and of transportation charges might be effected, thus placing American companies in a better position to compete for the business and benefiting users. In this connection it should be stated, also, with reference to all mining equipment, that greater study should be given to the matter of sectionalizing and shipping knocked-down. The increasing capacities and weights of machinery to be set up in distant countries render this more and more desirable. For improved grinding and amalgamating mills and reducing pans there are also good opportunities of sale.

American samplers, feeders, distributors, amalgam tables and traps, classifiers, launders, vanners, concentrating tables, pulp thickeners, filters, clarifying presses, agitators, furnaces, and retorts, are favorably regarded, for the most part, by European mine owners, and then sale ought to be extended far more than it has been. Concentrating apparatus can be easily demonstrated and if several American manufacturers were to unite in sending a joint exhibit abroad to be shown in, say, London, Paris, and Vienna, or Budapest, the returns would unquestionably justify the outlay many times over.

American gyratory breakers of the heaviest types easily surpass any crushing machinery made in Europe, and, while many such have recently been sold abroad, the surface of the possible demand has only been scratched. In Norway and Sweden, alone, the preparations now being made to open further vast deposits of iron ore for transportation to tide-water by electric railways or aerial systems, will lead to the erection of many plants such as that at Varanger Fjord, which was the first in the world to use a breaker as heavy as No. 18 for ore crushing, the largest previously in use anywhere having been No. 12. Sledging rolls of the Edison type can also be adapted to the same service, and the largest jaw crushers, up to 42 in. opening, will be used in future to a considerable extent. For crushers of the smaller varieties, such as the Blake and Dodge, as well as crushing rolls, the demand is limited by the competition of the excellent machines manufactured in England, Belgium, and Germany. The same is also true of trommels, screens, and various subsidiary apparatus.

American steam shovels and dredges are, generally speaking, far in advance of European models; and in their adaptation to mining work there is a widening field for sales to European operators. Compact electric-power outfits, sufficient to make these machines self-contained, can also be placed with them, but the purchaser's specifications should be obtained and carefully followed. Cranes, including the gantry and locomotive types, loading bridges, and other handling machinery will also sell well if properly introduced, particularly when prompt delivery is an object.

Furnaces and smelters constructed in accordance with American plans have grown in popularity as a result of favorable reports submitted by foreign engineers who have visited some of the principal plants in the United States, Mexico, and British Columbia. There are accordingly exceptional opportunities for the sale of the equipment comprised in such plants. This is true even of auxiliary details, from minor parts to blowers or blowing engines, as the tendency is to buy under one contract, thus concentrating the responsibility and guarantees. That tendency is not so observable in other lines, where orders are usually distributed among numerous concerns.

In magnetic separation European practice leads American, in my judgment, for the more common processes; but some complex problems have been worked out on this continent which can be profitably brought to the attention of mine owners on the other side where similar conditions exist.

The market for elevating and conveying machinery is constantly being extended, as the economies to be effected by the best modern systems become better known, and American manufacturers have every possible chance abroad of disposing of their products in this line. The same is true with reference to aerial tramways; but here our people will have to meet skilful and determined competition from English and German firms. In the design of conveying machinery, also, foreign manufacturers have shown great ingenuity in making belts, buckets, and pans do double duty by carrying different material on their return trip. Every advantage offered by gravity is also carefully taken. For ore cars and buckets the tendency is toward the larger sizes, with self-loading, tilting, and discharge—both compressed air and electric power being used for this purpose.

In the line of power-plant machinery, apart from hydro-electric units, Americans have little to offer Europeans other than boilers, super-heaters, economizers, and some auxiliary apparatus, the equal or superior of which cannot be found in Great Britain or on the Continent. An exception may possibly be made of engines to operate on producer-gas; but, as most of our improvements for that purpose originated in Belgium and Germany, it is not reasonable to suppose that the greater standardization and simplifying of parts, automatic adjustment to running conditions, at which our designers have arrived, will give American builders more than a temporary advantage. Pumping machinery manufactured in this country can ordinarily be sold to Europeans only in connection with complete outfits, but apparatus of proved economy for some special class of service is always given consideration. Hydraulic turbines and impulse wheels of American build are fully as efficient or more so than the best European designs. The latter have, in fact, been modeled of late years mainly after American types. There is, therefore, no reason why our builders should not get their fair share of this class of business for plants constructed in various parts of the world. Auxiliary details from banded wood pipe to governors and pressure regulators are also included.

What impressed me most, on the other side of the Atlantic, is the thoroughness with which everything connected with equipment and planning of operations is gone into by the company directors and their engineers. It would be well worth the while of manufacturers here to send some of their best men abroad, at intervals, on engineering or sales work, with a view to having them imbibe some of this spirit of exactitude. Loose or careless statements do not 'go' in Europe. An American who makes assertions of any kind regarding the efficiency of certain machinery or operating methods is pinned right down to the facts; and the exaggerations with which we are too familiar on this side, meet with prompt exposure. The larger companies would also find it beneficial to have the engineers whom they employ come in contact with European experts on their own ground. From those who visit this country they fail to get the same benefit of association, as they are not as communicative as when at home, and if they remain in this country to work they are apt to fall into the ways of Americans, or at least to refrain from criticism that would be wholesome. The traveler abroad is also surprised to find how widely diffused and intelligent is the attention given to mining, which has not come into the disrepute, from the standpoint of real investment, that has characterized the business in the United States. True, there is no lack in Europe of wild-cat companies and stock-jobbing schemes; but the placing of capital for small interests, as well as large, has been done, of late, in nearly every case upon a sound conservative basis.

In Cornwall, Wales, the Scandinavian countries, France, the Iberian peninsula, north Africa, Italy and the islands off its coast, Austria proper, Hungary, Bohemia, and Germany, old mining districts are beginning to be exploited on a more scientific basis; and, in places where the original purpose was to recover limited quantities of gold and silver, the baser metals are now sought. Southeastern Europe, including the Balkans, and Russian possessions from the western Ural ranges to eastern Siberia and the confines of Turkestan, will be extensively opened to mining operations with the next few years. Systematic exploitation of the vast mineral resources of northern and central Africa has already begun. From Morocco, where the more recent imbroglio really started in the efforts of the *Corps des Mines*, a French organization said to be backed by the Rothschilds, to get at the lead and other deposits in the Atlas mountains, to the *Haut Katanga* (Upper Congo) country bordering Rhodesia, various groups of capitalists are now behind prospecting and development work throughout what were in Stanley's time the 'dark' portions of the continent. Tin, copper, and diamonds are the principal attractions at present; and, within the coming decade, there will be some large plants put up for the treatment of the ore, that of copper in particular. One such plant, composed entirely of American equipment, is now going in not far from the western shores of Lake Tanganyika. Meanwhile railroads from the west coast, built under French, British, and Belgian auspices, are penetrating the country, opening it to further exploration and settlement. It will not be long before one of these effects a junction with the Cape to Cairo line. European capital, especially that of the Continent, is also seeking further fields of development in Mexico, Central, and South America, in some of the islands of the Pacific, and in the Far East from Borneo to Manchuria and Korea; while English and Scotch investors are paying more attention to northern India, Burma, Siam, and the colonies of the British Crown.

In all of this development American engineers cannot fail to play an important part; and the reflex influence upon methods used in this country, upon the manufacture and sale of machinery, and upon the world's metal markets, will unquestionably be great. The present high standing of American engineering, so far as it relates to mining and metallurgy, is due in no small measure to the publicity given it by the widespread circulation in Europe of the leading American mining journals. Both their reading columns and their advertisements have contributed to produce a favorable impression of American enterprise. It goes without saying that the *Mining and Scientific Press* has long been regarded abroad as an authority on mining standards; and in this connection I was interested to note how strongly *The Mining Magazine* has taken hold upon the European mining public, not only of Great Britain, but also on the Continent. Its vigorous editorials, denunciation of mal-administration or shams, and enterprise in bringing the world's progress in mining to the attention of its readers, has won for the journal a place in the ranks of conservatism which must surprise even its proprietors. The offices of the paper also serve as a rallying point for American mining engineers and salesmen and as a meeting place with European interests, which I heard spoken of by both parties with considerable appreciation. I found, however, that the business manager was overwhelmed with inquiries as to where the London or other European representatives of this or that American machinery mentioned in the descriptive articles of that paper and the *Press* were to be found. Many such questions can be readily answered from his own knowledge and from a classified file which he keeps; but frequently it takes a great deal of telephoning among other agencies to discover who is handling the apparatus, or else to learn that no representative for it exists. When American manufacturers do have agents abroad and are prepared to make sales through them, there is no excuse for keeping that fact generally unknown. The information ought at least to be given to the European offices of American mining journals and to American consuls in the leading commercial centres, all of whom will be glad to have it for reference. Nor should there be failure to follow this up with notification of any changes. One of the best means, also, of presenting the information prominently and keeping it fresh is to have a list of European representatives appear at the foot of advertisements. This is the method uniformly pursued by American machine tool builders, and is one reason why nearly two hundred of them are selling their products in Europe today.

European representatives, once selected, should be given adequate backing and support. They must be, themselves, thoroughly posted on the construction, special features, and operating advantages of the machines which they have to sell; their inquiries dictated by customers' requirements should have prompt attention at the home office; they should have the aid of good descriptive literature couched in terms comprehensible to European managers; and their promises of delivery, directions for shipment, terms of payment ought in all cases, if properly made, to be scrupulously complied with. Nor should they be led, through correspondence or otherwise, to make any claims for the apparatus which will not stand the most rigorous tests. For his own part, the manufacturer desirous of building up an export trade through sales to European mine-owners, should realize that respect for the established methods and traditions of European users of machinery is an important factor. There are decided advantages in voluntarily ascertaining and catering to these, instead of being driven into doing so. Yielding gracefully to unavoidable conditions, instead of vainly combatting them, also avoids many troublesome situations; and in dealing with Europeans of any class the value of absolute good feeling and courtesy is not to be overestimated.

Suggestions on Cyanide Practice

By J. B. Stewart

Several writers have from time to time called attention to the advisability of separate treatment for natural slime. I think that much may be done in this direction to develop the highest efficiency in many plants. E. M. Hamilton has pointed out that at El Rayo mine a higher net profit per day was obtained by treating very fine sand separate from the slime. The essential reason for this treatment at El Rayo was that whereas the extraction obtained from the sand and slime when collectively treated was just as high as when separately treated, still the time of treatment required for such an extraction reduced the capacity of the plant a great deal. By treating separately, a shorter treatment for the slime gave the maximum extraction, and only a trifle longer treatment was required on the sand. The result was more tons treated per 24 hours with the same equipment and a higher return with no increase of costs. In the same way I believe that the natural slime separated before final regrinding begins, would yield the maximum extraction much quicker. In this direction I expect much advance in reducing tank capacity and volume of solution.

The success reported for the Just process must call for considerable argument in the near future, regarding the relative merits of two theories which seek to explain the best conditions for rapid dissolution of silver values in a slime charge. I would like to see the topic 'Diffusion versus Circulation' discussed. Is it necessary to circulate solution faster or slower than the slime, to promote a perfect diffusion of the dissolved values, from the immediate surface of the slime particles to the general mass of solution? Or can the same rate of extraction, accomplished by the above method, be obtained by merely keeping the slime particles suspended in the solution, depending upon a purely physico-chemical diffusion of the dissolved metals rather than mechanically assisting such an action?

Touching on the subject of the economic limit for moisture in the feed for a tube-mill, it is only necessary to note the difference between the consistence of sand and slime, each containing 25% moisture, to realize that whereas the sand might grind all right at that dilution, certainly the slime would not do so. As the surface of the material increases, due to reduction in size of its grains, the amount of moisture required to keep it mobile necessarily increases. This points to the advantage of stage grinding in which, for instance, ¼-mesh product could be introduced at 20% moisture in the first stage and after classifying the discharge, the second stage could be conducted with 39% as suggested by Walter Neal's experience at Dos Estrellas.

Next, as to stage grinding, I wonder that the advantages of this refinement have not made greater headway in general practice, and I also wonder why the high-speed Chilean mill has come into favor instead of a short-length tube-mill as the intermediate grinding unit, in several large companies which have already adopted stage grinding. Certainly the operating cost for the Chileans must be much greater than it would be for 15-ft. tube-mills. In fact, I should consider the tube-mill more efficient in power, duty, labor, and supplies than the Chileans.

In conjunction with stage grinding as already suggested, it would seem preferable to use the Callow screen to separate the coarse feed for the primary grinders and Dorr classifiers for the secondary mills. Whereas there can be no doubt of the efficiency of the cones provided with diaphragms, as described by Mr. Neal, for dewatering a tube-mill feed, still I doubt whether they lend themselves so well as the Dorr classifiers do, to re-handling the entire discharge of the tube-mill. The Dorr machine is a classifier and a dewatering machine as well, with no rival for compactness and saving in grade or elevation about the plant. On the other hand, the dewatering cones using baffles must be preceded by other cones for separating the greater bulk of slime, and this entails much more difference in elevation.

The Electrical Precipitation of Suspended Particles

By F. G. Cottrell.

*The removal of suspended particles, from gases, by the aid of electric discharges is by no means a new idea. As early as 1824 it was suggested by Hohlfeld[1] as a means of suppressing ordinary smoke, and again a quarter of a century later by Guitard.[2] These suggestions, which do not seem to have stimulated any practical study of the question, were soon entirely forgotten and only brought to light again by Sir Oliver Lodge[3] many years after he himself had independently rediscovered the same phenomena and brought them to public attention[4] in a lecture before the Liverpool Section of the Society of Chemical Industry, November 3, 1886. The first recorded attempt to apply these principles commercially appears to have been made at the Dee Bank lead works. The general principle of electrical precipitation of suspended matter was at this time patented by Alfred O. Walker, of the above firm, in several countries,[5] but these patents have long since expired. The apparatus was erected in 1885 by the works manager, W. M. Hutchings, with the cooperation of Mr. Lodge, and briefly described by the former just before its completion as consisting of a system of metallic points situated in the flue from the lead furnaces and excited from two Wimshurst influence machines with glass plates 5 ft. in diameter, each machine being driven by a 1-hp. steam-engine.

The apparatus undoubtedly did not in practice fulfill expectations, as nothing further is found of it in the literature. The most apparent weakness of the project lay, perhaps, in the reliance on the Wimshurst machine, which had then just been brought out and from which a great deal more was anticipated[6] that has been justified by experience, at least as far as commercial applications are concerned.

Since that time an occasional patent[7] or article[8] has served to keep the subject in the public eye, and in 1903 Lodge himself took out a patent[9] covering the use of the then new mercury arc for rectifying high potential alternating currents for this purpose. Up to the present time none of these patents seem to have been carried into successful commercial operation on the large scale in the chemical or metallurgical industries. Some four years ago while studying various methods for the removal of acid mists in the contact sulphuric acid process, I had occasion to repeat the early experiments of Lodge, and became convinced of the possibility of developing them commercially. The work here described may fairly be considered as simply the reduction to engineering practice as regards equipment and construction, of the fundamental processes long since laid open to us by the splendid pioneer work of Lodge, a feat vastly easier today than at the time of the original attempt.

The precipitation of suspended matter, whether in gases or liquids, may be accelerated by electricity in the form of either direct or alternating current, but the mode of action and the type of problem to which each is best applicable differ in certain important respects. Where an alternating electromotive force is applied to a suspension, the action consists for the most part in an agglomeration of the suspended particles into larger aggregates out in the body of the suspending medium and a consequently more rapid settling of these aggregates under the influence of gravity. Thus, if powerful Hertzian waves are sent out into foggy air, the alternating fields set up in space cause an agglomeration of the particles of liquid into larger drops which then settle more rapidly. Considerable work aimed at the application of this phenomenon to the dispelling of fog on land and sea has recently been done in France and England, but little as to definite results seems as yet to have been published. The field appears, however, one of considerable promise. Another application of alternating current along these lines is found in a process now in use in the California oilfields for separating emulsified water from crude oil. This process grew out of the work here described and was developed some two years ago by Buckner Speed and myself to meet certain peculiar conditions existing in these fields.[10] Alternating current may thus be used to advantage where the masses of gas or liquid to be treated are fairly quiescent and a simple agglomeration of the suspended particles into larger aggregates is sufficient to effect separation by gravity or otherwise.

In the case of the large volumes of rapidly moving gases in smelter flues, the agglomerating and settling process is, however, too slow even when the flues are expanded into as large dust chambers as are commercially feasible. It is in such cases that direct-current methods have been particularly important. If a needle point connected to one side of a high-potential direct-current line be brought opposite a flat plate connected to the other side of the line, the air space between becomes highly charged with electricity of the same sign as the needle point; irrespective of whether this is positive or negative. Any insulated body brought into this space instantly receives a charge of the same sign. If this body is free to move, as in the case of a floating particle, it will be attracted to the plate of opposite charge and will move at a rate proportional to its charge and the potential gradient between the point and plate. Even if there are no visible suspended particles, the gas molecules themselves undergo this same process, as is evidenced by a strong wind from the point to the plate even in perfectly transparent gases. The familiar experiment of blowing out a candle flame by presenting it to such a changed point, is simply another illustration of the same phenomenon.

As above indicated, the first step toward practicability was of necessity a commercially feasible source of high-tension direct current. The obstacles to building ordinary direct-current generators for high voltages lie chiefly in difficulties of insulation, and if this is avoided as to individual machines by working a large number in series, the multiplication of adjustments and moving parts intrudes itself. On the other hand, high-potential alternating-current technique has in late years been worked out most thoroughly, and commercial apparatus up to 100,000 volts is available in the market. The mercury arc rectifier has been made practical for series arc lighting service up to some 5000 volts direct current, but although higher voltage units were at one time attempted by the electrical companies, they were later withdrawn from the market as unsuited to practical operating conditions. For high volt-

ages they seem, like the static machines, to work well under the careful management and light duty of the laboratory, but fail in practice. This is particularly so in the application to metallurgical and chemical work where the electrodes in the flues have to be placed close together and worked near the potential of disruptive discharge, the occasional occurrence of which later places much more severe requirements upon generating apparatus than in the case of the series arc lighting, to which the rectifier seems particularly well adapted. This restriction does not necessarily apply to the conditions under which fog and smoke would be treated in the open air. It is to these latter cases that Lodge's efforts in late years seem to have been the more particularly directed, and here the mercury rectifier in connection with high-potential transformers may find a useful field.

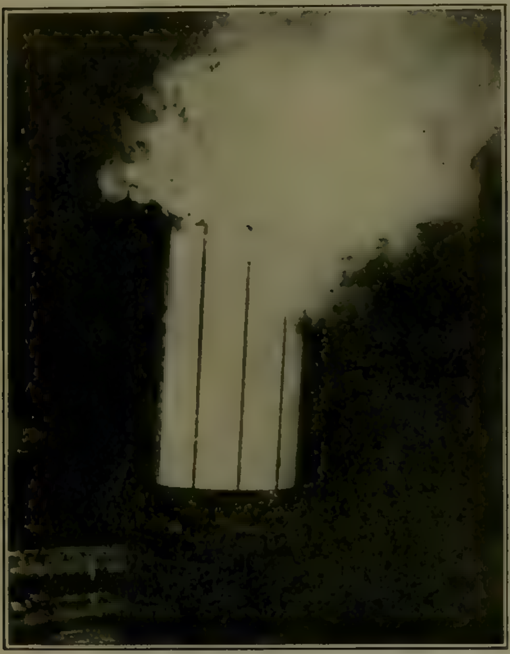

Fig. 1. ACID FUMES AT POWDER WORKS WITHOUT CURRENT ON APPARATUS.

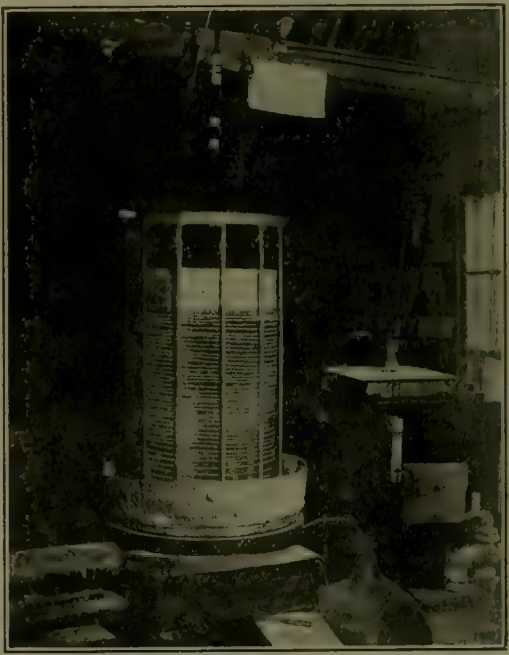

Fig. 2. ACID FUMES AT POWDER WORKS WITH CURRENT ON APPARATUS, ONE MINUTE AFTER.

The procedure actually followed in the work described below consisted in transforming the alternating current from an ordinary lighting or power circuit up to some 20,000 or 30,000 volts and then commutating this high-potential current into an intermittent direct current by means of a special rotary contact-maker driven by a synchronous motor. This direct current is applied to a system of electrodes in the flue carrying the gases to be treated. The electrodes are of two types corresponding to the plate and point in the experiment above cited. The construction of electrodes corresponding to the plate presents no special problem, as any smooth conducting surface will answer the purpose. With the pointed or discharge electrodes it is quite otherwise, and the working out of practical forms for these has proved the key to much of the success thus far obtained. In laboratory experiments, when the discharge from a single point or a few such is being studied, fine sewing needles or even wire bristles answer very well, but when it is attempted to greatly multiply such discharge points in order to uniformly treat a large mass of rapidly moving gas at moderate temperatures, great difficulty is met in obtaining a powerful and, at the same time, effective distribution of current.

It may be of interest to note that the clue to the solution of this difficulty came from an almost accidental observation. Working one evening in the twilight when the efficiency of the different points could be roughly judged by the pale luminous discharge from them, it was noticed that under the particular conditions employed at the time, this glow only became appreciable when the points had approached the plates almost to within the distance for disruptive discharge, while at the same time a piece of cotton-covered magnet wire which carried the current from the transformer and commutator to the discharge electrodes, although widely separated from any conductor of opposite polarity, showed a beautiful uniform purple glow along its whole length. The explanation lay in the fact that every loose fiber of the cotton insulation, although a relatively poor conductor compared to a metallic point, was still sufficiently conductive from its natural hygroscopic moisture to act as a discharge point for this high-potential current, and its fineness and sharpness, of course, far exceeded that of the sharpest needle or thinnest metallic wire. Acting on this suggestion, it was found that a piece of this cotton-covered wire when used as a discharge electrode at ordinary temperature proved far more effective in precipitating the sulphuric acid mists, which were then the object of study, than any system of metallic points which it had been possible to construct. Perhaps the greatest advantage thus gained lay in the less accurate spacing demanded between the electrodes of opposite polarity in order to secure a reasonably uniform discharge.

In practice a more durable material than cotton was demanded for the hot acid gases to be treated, and this has been found in asbestos or mica, the fine filaments of the one and the scales of the other supplying the discharge points or edges of the excessive fineness required. These materials are twisted up with wires or otherwise fastened to suitable metallic supports to form the discharge electrodes in such wise that the current has to pass only a short distance by surface leakage over them, the slight deposit of moisture or acid fume naturally settling on them serving to effect the conduction. If the condition of the gases does not supply sufficiently such coating, then a special treatment of the material before being placed in the flue is resorted to. The construction and arrangement of the electrodes as also of the chamber containing them naturally vary widely with the conditions to be fulfilled under the varied applications to which the process may be put. Some of the more general features of this work are described in the patents[11] already issued in this and foreign countries, while further details and modifications are covered in other patents not yet issued.

---

[11] U. S. Pat., 866,843. 895,729, and 945.717.

Following development of satisfactory laboratory apparatus the attempt was made to duplicate the experiments on a scale some two hundred fold larger. This was carried out during the summer of 1906 at the Hercules works of the E. I. du Pont de Nemours Powder Co. at Pinole on San Francisco Bay, where the contact gases from one of their Mannheim contact sulphuric acid units were available. These gases at the point selected contained about 1% by volume of dry gaseous sulphur trioxide, and in order to convert this into sulphuric acid mist they were brought into contact with water. Under these conditions very little of the sulphur trioxide is absorbed by the liquid water, but the latter evaporating into the gas combines with the sulphur trioxide to form the far less volatile sulphuric acid which immediately separates as a dense white cloud of suspended particles so fine as to represent one of the most difficult of all materials to remove by filtration. Fig. 1 and Fig. 2 are from photographs taken a minute apart with the same current of fume-laden gases passing into the precipitation-chamber, but with the electric current respectively off and on. The apparatus consisted of two concentric cylinders which formed a discharge electrode, while intermediate in diameter between these two and resting on the lead pan-bottom of the apparatus was a third cylinder, also of iron-wire screen, but without asbestos winding, which together with the outer leaded glass cylinder constituted the collecting electrodes. The precipitated acid drained off from this precipitation chamber into the carboy on the right. The space between successive cylinders of opposite polarity was as nearly as possible an inch and a quarter. Current was supplied from three 1-kw., 110 to 2200-v. transformers connected in series on their 2200-v. side to give 6600 v. The fume was delivered to the bottom of the precipitation-chamber at its centre and had to pass through the three-wire cylinders and up between the outer of these and the glass container, thus being subjected to three electric fields in succession. In this apparatus the power-consumption was about one-fifth of a kilowatt, and between 100 and 200 cu. ft. of gas per minute could readily be treated. This apparatus was merely for experimental and demonstration purposes, but a still larger unit, built for permanent operation and to handle all of the gas from a Mannheim unit, has since been erected at this plant and put into steady commercial operation.

These experiments at Pinole attracted the attention of the Selby Smelting & Lead Co., whose smelter situated at Vallejo Junction, a few miles farther up the bay, was at that time the object of injunction proceedings brought by the farmers of the surrounding country. At the time the suits originated, three separate stacks at the smelter contributed to the alleged nuisance. The first, and admittedly the most serious offender, handled the gases from the lead blast furnaces and discharged several tons of lead fume daily into the air. Shortly before the commencement of experimental work at the plant, this had been obviated by the erection of the bag house. After correcting this evil, there still remained, however, a stack discharging the gases from the roasters, which, besides the invisible sulphur dioxide, furnished dense white clouds consisting chiefly of sulphuric acid, arsenic, and lead salts, and to which the bag-house was inapplicable on account of the corrosive action of these gases upon the bags. Lastly, there was the stack of the refinery carrying the mists escaping from the pots of boiling sulphuric acid used to dissolve the silver out of the gold and silver alloy coming from the cupels.

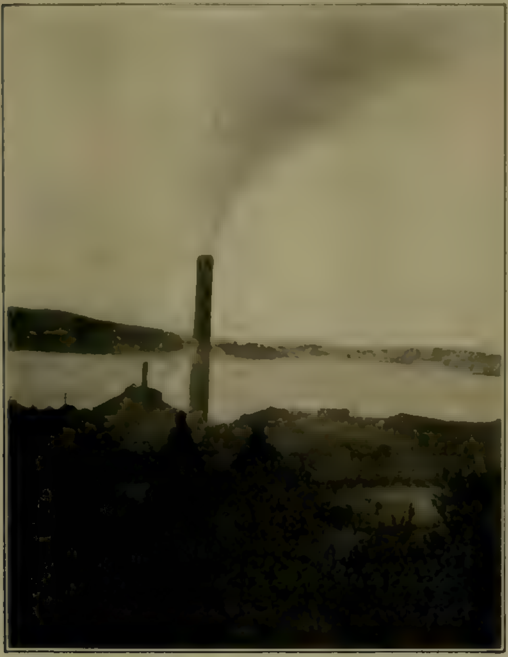

Fig. 3. GASES FROM BLAST-FURNACES AND ROASTERS AT SELBY WORKS, WITHOUT CURRENT ON APPARATUS.

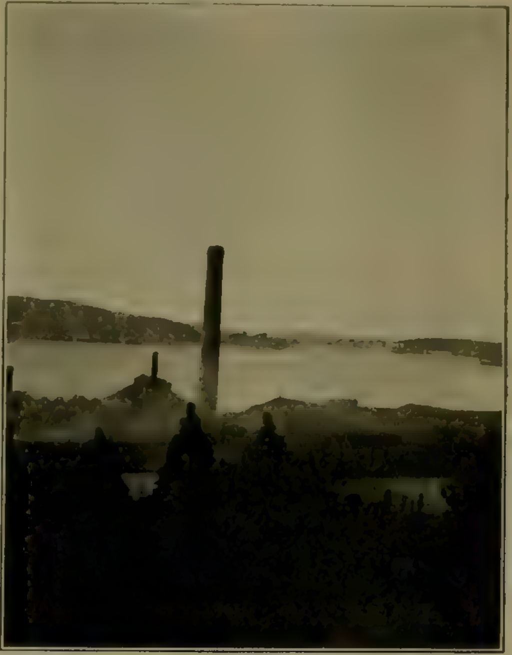

Fig. 4. GASES FROM BLAST-FURNACES AND ROASTERS AT SELBY WORKS, WITH CURRENT ON APPARATUS.

The blast-furnace and the roaster stacks each carried something over 50,000 cu. ft. of gas per minute, while the refinery stack represented scarcely a tenth of this volume. As a first step, operations were begun on this latter, and after several months' experimenting as to the best form of construction, a system of vertical lead plates 4 in. wide by 4 ft. in length and spaced about 4 in. apart, was developed. Several rows of such plates were assembled in a 4 by 4-ft. lead flue. Between each pair of plates hung a lead-covered iron rod carrying the asbestos or mica discharge material, the latter finally proving the more serviceable in this highly acid atmosphere. These rods or discharge electrodes were supported on a gridwork of buss bars extending over the heads of the plates and through apertures in the sides of the flue to insulators on the outside.

The electric current is taken from the power circuit of the plant at 460 volts, 60 cycles, and transformed up to 17,000 volts, thence through the synchronous contact-maker or rectifier to the electrode system. At first a glass-plate condenser was connected across the high-potential line in parallel with the electrode system in order to assist in maintaining the potential of the electrodes between the intervals of contact, but was found troublesome and unnecessary in practice, and in this and other installations is now omitted. The power-consumption is about 2 kw., including the driving current for the synchronous motor. The switchboard transformer and rectifier are in the engine-room of the plant and require no more attention than a feed-pump or a blower. The plant has now been in successful daily operation for over three years at a cost for labor, attendance, and repairs of less than $20 per month. In fact, while the plant was making enough bluestone to utilize all the weak acid recovered, the saving on purchase of the latter paid for the entire cost of operating five times over.

The next undertaking was naturally an extension of the process to the treatment of the gases coming from the pyrite and matte roasters of the same plant. This presented a somewhat more difficult problem, as the material to be removed consisted of a mixture of solid dust and fume with liquid sulphuric acid. From small-scale experiments it was at first thought possible to precipitate the material in a reasonably dry form and shake it in this condition from the electrodes, thus permitting of brick and iron construction. Quite an extensive plant was erected on this plan. It consisted of four parallel brick flues or chambers, each 22 ft. long, 7 ft. wide, and 9 ft. deep, and containing an electrode system of iron plates as grounded or collecting electrodes, and wire and asbestos discharge electrodes somewhat similar in general arrangement to that in the refinery flue. In this case, however, the insulating supports of the discharge electrodes were carried above the flue. This type of equipment was found poorly adapted to the particular gas conditions here present, as a much higher proportion of free sulphuric acid was encountered than the preliminary tests had given reason to expect, the weight of this free acid often exceeding, in fact, that of all the solids in the gas put together. The gases were also highly charged with water vapor both from the wet ore and the steam-atomizing oil-burners in the roasters, and this tended further to dilute the acid and produce a muddy deposit. The iron and brick construction made removal of this deposit by washing impracticable, so it was decided to further cool the gases and treat them in a lead flue similar to that used in the case of the refinery. However, the experience gained with the large brick flues in which a wide variety of electrodes were tested, made it possible to compress this new construction into far smaller compass than would otherwise have been thought possible.

The resulting construction was a sheet-lead flue of 6 by 6-ft. cross-section and 32 ft. long, containing 38 rows of 16 lead plates each 6 ft. long by 4 in. wide, with the corresponding discharge electrodes between each pair. The effect of the treatment upon the appearance of the gases issuing from the stack is shown in Fig. 3 and Fig. 4, which represent respectively the electric current switched off and on, being taken about three minutes apart. It should be remembered that in this 32 ft. of 6 by 6-ft. flue about the same volume of gases was being treated as in the bag-house, measuring about 98 by 125 by 55 ft., and further that actual tests showed that even the woolen bags used in this bag-house are completely destroyed by these roaster gases in less than half an hour. This gives a better idea of some of the possibilities which this process appears to open. The power-consumption in this case was between 10 and 15 kw. The material precipitated upon the plates was a grayish mud easily washed off and drained out through the bottom of the flue to settlers. For this purpose it was necessary, once in about every four to six hours, to by-pass the gases, shut off the current from the flue, raise its covers, and close down the electrodes from above. One man could easily carry out this whole operation in from five to ten minutes. For continuous operation on such material it is, of course, necessary to subdivide the treatment into two or more units in order that while one is being cleaned the others may be in operation.

In order to insure that essentially all the free sulphuric acid and arsenic of these roaster gases should be condensed from true gases into suspended particles, which latter are all the apparatus purports to collect, and also to protect the lead construction from softening from the heat, it was found necessary to cool the gases down to less than 150° C. To accomplish this a system of water sprays was first used in the mouth of the lead flue just before the electrodes. This served the purpose as long as clean water which would not stop the sprays was available, and successful test-runs of a week or more duration were made with this system, but as the circulating and cooling water of the entire plant is derived from the Sacramento river, which is often very muddy, the difficulties of keeping the sprays clean and open determined the management of the plant to resort to cooling by radiation through a lengthening of the flue before the precipitator. This construction and the refitting of the apparatus for continuous operation has not as yet been undertaken, and as the litigation with the farmers seems, for the present at least, to have centred more about the question of sulphur dioxide, it is likely that the completion of the work will be allowed to await the reaching of an understanding on this matter.

(To be Continued.)

Troitzk Gold Mine

The Troitzk Goldfields, Ltd., owning important mines in western Siberia, after early financial trouble, was reorganized by Hooper, Speak & Feilding. A new treatment-plant was erected, consisting of 6 Chile mills, amalgamating and cyanide plant, and much prospecting and development work was done under the direction of their resident partner, H. C. Bayldon. The new mill started work in August 1909, and work was continuous until May 25 of this year, when a fire broke out in the Stanley shaft, and not only caused the mouth of the shaft to collapse, but ruined the hoisting-plant, pumps, and air-compressor. This calamity has hastened the crisis which was impending, owing to the inability of the mine to pay its way, and a scheme of reorganization is being prepared for the purpose of refunding the loan of £58,000 advanced by the parent company, the Siberian Proprietary, and of raising £45,000 further working capital. Six months ago Mr. Bayldon had submitted a report suggesting the improvement of the position of things. One trouble was that suitable labor is scarce, and it was therefore proposed to take steps to collect a settled mining population. Other proposals were to suspend milling for a few months in order to press forward development work, and to provide an additional cyanide plant, especially for the treatment of slime. The directors have proposed and the shareholders have approved that this new work shall go forward. The report for 1910 shows that the Chilean mills treated 40,628 tons of ore and that 8257 oz. was extracted by amalgamation, 1476 oz. recovered by cyaniding sand, and 469 oz. recovered by cyaniding concentrate, making a total of 10,202 oz., being an extraction of 79% of the estimated content of the ore. The receipts from the sale of gold were £42,930, and the cost, including interest on loans, depreciation, and development redemption, was £52,359. The ore reserve on December 31 was given at 40,400 tons averaging 7½ dwt. Owing to the lenticular shape of the orebodies, it is not possible to give close figures, but judging by experience it is probable that there is a greater amount of ore available for stoping than is included in the estimate. The method proposed for raising the new capital is to create 124,993 priority shares of £1 each, entitling the holders to 90% of the profits available for dividend each year; of these 104,993 are being offered to shareholders for subscription.

THE PURPOSE of breathing apparatus used in mine-rescue work is to supply the wearer with oxygen, and to absorb the carbon dioxide and the moisture exhaled in his breath. To accomplish this purpose, the apparatus is so made as to permit the wearer to use the oxygen that is exhaled in his breath, and to permit him to breathe over and over again the nitrogen that is in his lungs and any that is inside the apparatus.

Philippine Placers

By R. Y. Hanson

Gold-bearing alluvium has been discovered in many widely scattered localities throughout the Islands, from northern Luzon to Mindanao, but with the exception of the Paracale, [illegible] and Malaguit districts, in Camarines province, southeastern Luzon, [illegible] the old Spanish reports is available. Recently the northern coast of Mindanao in the vicinity of Surigao and Cagayan has been attracting attention and, if the reports from these places are to be credited, large areas of workable and dredging ground may be developed in the near future. The district of Nueva Ecija, some sixty miles north of Manila, contains thousands of acres of gravel deposits, parts of which have been examined in a cursory manner with varying results. A thorough examination of the field might show the existence of good pay channels or deposits, but as yet nothing other than the existence of submerged clay beds of varying thickness has been proved. Systematic drilling by those holding claims in the district would be a move in the right direction. The judicious expenditure of $100 per annum, upon each group would in a few years sufficiently demonstrate the advisability of retention of the property.

The Malaguit river in Ambos Camarines, bids fair to become an important dredging field, and, equipped with modern dredges designed to handle ground of the character found in the district, should yield substantial returns. There are probably 3000 acres of alluvium upon the river, which extends from the sea a distance of about six miles before the higher plateaus are reached. This area is all a tidal plain covered with a profusion of *manglar* (mangrove) timber and buried from 2 to 4 ft. deep at high tide. The deposit consists of a topping of loam and decayed vegetation, clay, and sand, over a clean angular gravel free from large boulders and resting upon a soft to medium hard schist and granite bedrock which is quite irregular and prone to contain fissures. This description applies particularly to the upper reaches. The lower section possesses a soft decomposed bedrock which is fairly regular and usually a granite. The depth of the alluvium varies from 18 to 24 ft. at the Philippine Gold Dredging Co.'s dredge, some four miles from the sea, to 35 and 40 ft. near the river's mouth. The dredge now operating upon the river is a Risdon 3½-cu. ft. loose-connected or link-bucket type capable of handling from 30,000 to 40,000 cu. yd. per month under favorable conditions and in ground of the character for which it was designed. The actual yardage being dredged per month, in the material being worked, does not exceed 20,000, and is perhaps nearer 15,000 cu. yd., which, on the basis of the gold won plus 25% for losses, gives an actual gold content of 25c. per cubic yard. The approximate working costs, exclusive of depreciation, office expense, and interest on the investment, upon the above basis are 10c. gold per cubic yard. Owing to the fact that no record is kept of anything other than the number of ounces of gold won per month or fortnightly, an accurate estimate is impossible either here or upon the Paracale dredges, where the system is in vogue.

The Paracale district, the most widely known field in the Islands and the only one until recently upon which any dredges had been successfully operated, is situated upon the Paracale river and several branch streams which lie beyond a ridge about one-half mile north of the Malaguit river, but, unlike the Malaguit deposit, the Paracale ground lies almost entirely in an elliptical basin and contains some 2000 acres of alluvium some 300 acres of which are in narrow valleys leading from the basin. The deposit, with the exception of a 300-acre cocoanut grove bordering the bay and the upper reaches of the streams, is submerged from 2 to 4 ft. at high tide and covered with *manglar* timber which appears quite formidable to one unacquainted with its characteristics, but which offers no serious obstacle to dredging and which might even be considered a valuable asset as it makes excellent firewood when dried and affords the most desirable fuel for power around at a very nominal cost, about $1.25 per cord. The deposit consists of a stony clay over a clayey sand, sometimes quite tough, especially in the cocoanut plantation, underlain by gravel consisting, in the main, of quartz fragments and sand and occasionally a small percentage of clay. The quartz fragments are small in the valleys and the upper portion of the basin. In the lower section they are coarse and large fragments, weighing several hundredweight are found. These are saved and run through a 5-ft. Huntington mill yielding an average of $15 per ton in free gold. The concentrate from a Wilfley table is saved for shipment and is reported to be worth about $100 per ton.

The bedrock throughout the deposit is a soft decomposed granite or schist, schist predominating, and possesses a uniform grade or slope toward the sea. The thickness of the alluvium varies from 15 ft. at the upper end of the valleys to 45 ft. at the lower where the Paracale dredge is now operating. The gold is in nugget form, coarse and fine, with an appreciable quantity of flour. It is clean and lends itself readily to amalgamation. The roughness of the larger particles indicates clearly the local origin of the deposit, evidently by erosion from the veins and stringers in the schist of the surrounding hills. Practically all of the gold is found in the bottom layer, which ranges in thickness from a few inches to several feet. The percentage of black sand is large; about one ton to the thousand yards. The sand is found in varying quantities throughout the deposit. It assays $100 per ton and might prove valuable if economical means of saving it could be evolved.

At present there is only one dredge operating in the field, the other having been idle for the past year on account of litigation. Both these dredges are of New Zealand design and manufacture and equipped with 5-cu. ft. open-connected buckets and dig on a head-line. They are steam-driven and of low power, consuming about 3 cords of wood daily. As a matter of fact, neither of these was designed to handle the ground being dredged and their efficiency is less than 50% of the proper working capacity of 2000 cu. yd. per 24-hour day.

The total area of ground excavated by the Paracale Gold Dredging Co. dredge has been about 6 acres, from which has been won some $200,000. The depth has averaged about 45 ft., which would give a total yardage handled of about 450,000, showing an approximate saving of 45c. gold per cu. yd. The extraction has been low, certainly less than 80%. Those familiar with the operation of the dredge place it at about 50%, but the probabilities are that 75% would be more nearly correct. This would give an average gold content of 60c. per cubic yard for the area excavated, the high average being due to the fact that a rich pocket of considerable area was found a year or more ago. It is hardly to be expected that the entire district will average nearly so well, but as yet sufficient data are lacking to determine this point. However, there is every reason to believe that the entire district will prove profitable if handled by one or two large companies with sufficient capital to enable the joint equipment with several large capacity modern dredges, preferably with close-connected bucket-lines and a large table area with water under high pressure. No single operation with its attendant extra expenses, which might be divided among three or more boats, can work under the conditions obtaining in that section of the Islands, for a per cubic yard cost of much less than 10c. gold, but a consolidation operating three or more dredges should cut the expenses of operation to 7 and possibly to 5c. per cu. yd. The greatest obstacle at present is poor transportation and terminal facilities, the next is the large quantity of sand and other disintegrated material to be washed over the tables, and the third worthy of mention is the labor problem, which is always an important factor to be considered here in the Philippines. The first adverse condition could be readily improved should sufficient dredges be put in operation to warrant the service; the second could be remedied by the adoption of suitable machinery, and the third by less stringent alien laws.

Oilfields of the Trans-Pecos Region in Texas

By H. Vincent Wallace

The Trans-Pecos lies between Long. 103°40′W. to 104° 40′W. and Lat. 31 and 32°N., and more particularly includes those lands lying to the north of the Texas & Pacific railroad from Van Horn station on the west (which lies at the south end of the Sierra Diablo and Salt basin), the Texas and New Mexico boundary on the north, and Rustler springs, Maverick springs, and Toyah on the north and east; all embraced in parts of El Paso and Reeves counties. Toyah lies about 190 miles by rail from El Paso, and Van Horn some 60 miles nearer. On leaving Van Horn (elevation 4039 ft.), the south end of Salt basin, which at its lowest point lies some 500 ft. below Van Horn, is crossed, then the road gradually rises until at Mann's ranch, in Sec. 40, of Block 94, T. 5, an altitude of 4400 ft. is reached, or 361 ft. higher than Van Horn, and 861 ft. higher than that portion of Salt basin referred to.

According to G. B. Richardson, the age of the formation, around the base of the mountain to the north of Van Horn, is pre-Cambrian overlain by the Van Horn formation of the Ordovician; the base of the latter being marked by calcareous sandstones. On the eastern side of Salt basin lie the Delaware mountains (the southern extension of the Guadalupe range), which attain an altitude of 4600 ft. in Block 92, T. 5. They present a bold scarp to the west, and constitute the top of a gently sloping monocline, which dips east at a very slight angle, or a trifle south of east.

From Salt basin up over the escarpment of the Delaware mountains, one passes successively from the older to the more recent geological formations, and the Delaware range, embracing rocks of Permian age, is made of rocks locally known as the Delaware mountain formation. At the base of this formation, which is composed essentially of sandstones and limestones, is a bed of blue-black highly bituminous non-magnesian limestone, of which some 200 ft. is exposed, and is worthy of particular notice. As already stated, Permian rocks include the entire Delaware mountain formation, and for the present what is known as the Capitan limestone, which generally conformably overlies it, and the Castile gypsum and Rustler hills formation. All these are grouped together, though their ages are not definitely known. On the top of the Capitan peak of the Guadalupes, the limestone from which it is named is an almost pure dolomite, but the general distribution of the magnesian contents has not yet been accurately determined.

The Castile gypsum occupies a large belt and outcrops between the Delawares and the Rustler hills, and Mr. Richardson refers to the unconformity of the gypsum, as evidenced by the absence of the Capitan limestone, which should, according to him, lie directly under the Gypsum and over the Delaware mountain formation proper. I am inclined to believe that the Capitan limestone and the Castile gypsum really belong to the same period, the former having been converted by chemical agencies from the carbonate to sulphate. My reason for this assumption is that occasional layers or beds of what I consider the original limestone occur intercalated with beds of gypsum. The limestone is banded, is gray in color, and both it and the gypsum in most localities, on being struck or rubbed, give a characteristic bituminous odor. I am therefore inclined to think that, as the result of the action of sulphurous and sulphuric acid solutions, gasses, or vapors, the original carbonates have been converted more or less into sulphates. I fully realize that this is in opposition to theories of the deposition of gypsum from sea water, or almost land-locked estuaries, as suggested by Ochsenius, and as set forth by J. F. Kemp, in his 'Handbook of Rocks.' This theory requires the presence of layers of rock-salt alternating with gypsum. In the field under notice the northern portion of Salt basin is, I believe, the only region where sodium chloride is found in any considerable quantity.

The origin of the sulphur which is found in and adjacent to certain portions of the gypsum, may be the result of the absorption of sulphur by certain bacteria, a discussion of which may be found as a footnote to pages 37 and 38, of the 'University of Texas Mineral Survey Bulletin No. 2.' Assuming that certain bacteria or algae first took up the sulphur, and in turn set it free to form sulphuretted hydrogen, there is a basis for the formation of the gypsum and free sulphur, as set forth by Bischof. This theory dispenses with the necessity for volcanic agencies for the formation of the sulphurous gas and its consequently sulphuric condition. This, I appreciate, is in distinct opposition to Eugene Coste, both on the theory of the origin of the sulphur, and according to him, of petroleum, which he maintains is absolutely of volcanic origin.

Caves in the gypsum are numerous and indicate a line of weakness, where the acid gases or vapors or waters probably found outlets. Accompanying such gases, under considerable pressure, more or less bituminous matter was conveyed along the lines of least resistance, and deposited throughout the limestone beds simultaneously with the chemical activity which, I assume, was converting the carbonates to sulphates of lime. Where the limestone is shaly in character the concentration of the bituminous matter seems more in evidence, hence the finely banded limestone (with more or less sulphate), which did not afford a ready escape or vent, is more highly impregnated with bitumen than the more pervious portions of the formation.

zons.

Robert T. Hill in his paper entitled 'The Beaumont and Other Oil Fields of Texas,'[*] says:

"Capt. Lucas, who, in his explorations of the coastal plain seeking successively salt, sulphur, and oil, has observed the association of oil, sulphur, sulphuretted hydrogen gas, gypsum, dolomite, and salt, constituting collectively what might be termed the 'oil phenomena,' representing a group of secondary products, as distinguished from the mother-strata or sediments out of which they have been produced."

Strictly speaking, the origin of petroleum is as yet unknown. From the knowledge of known fields, it appears that commercial oil is found in rocks of almost all ages, the oil itself being usually found in more or less porous receptacles of sandstone, overlying highly impregnated shale or lime beds. These latter were presumably the original depository, but pressure, either hydrostatic or gaseous, or both, may have caused the transposition of some of this oil from the underlying strata to the overlying and more pervious sandstone. In order, however, that this transposed oil may retain its best qualities it is important that it be capped or sealed by a stratum which is impervious. Such a cap or seal may consist of chemical deposits, as magnesian-calcareous, silicious-calcareous, or possibly resedimented gypseous material, stiff clays, or, when more hardened, shales. The finer the texture of the overlying material the more impervious it would be to volatile matter. Now in the processes of nature, the folding of strata, caused by lateral or upward pressure, or through shrinkage, if carried to the point of fracture, would doubtless have permitted the travel of portions of the lower oils from lower strata, all probably aided by hydrostatic pressure, until they reached other porous receptacles at higher hori-

In addition to the favorable conditions discussed by M. L. Requa in the January number of *The Mining Magazine*, in 'Oil Resources of California,' I would add an extract from W. Topley, in a paper read before the British Association in 1891, entitled 'Geology of Petroleum and Natural Gas,' in which he in part sums up his views as follows: First, the most productive areas for oil in great quantity are where the strata [illegible]. Oil has [illegible] [illegible] found, [illegible] gas in [illegible] Seamy, the gas [illegible] gas is [illegible], etc. [illegible] pervious cover. [illegible] and [illegible] favors the accumulation of oil and gas in the [illegible] of the arches. Faults, [illegible] accompaniment of oil and gas.

---

[*] *Trans.* Amer. Inst. Min. Eng., Vol. XXXIII.

Referring to Mr. Topley's paper, it may be noted that in the region under discussion the strata are generally undisturbed, though thrown into a long and almost monotonous monocline continuing eastward from the western scarp of the Delawares. There is a low anticline running east between T. 5 and 6, and on Block 97 in Paint Horse draw there is an outcrop of fine yellow sandstone showing a section of 80 ft. in thickness, which dips southeast. This may be the southeast limb of a local fold, the exposure of the strata being caused by erosion in the Paint Horse draw. I was informed that many years ago a well drilled on Sec. 22 in the adjoining Block 101 reached a depth of 300 ft., all in sandstone. No water was found, but a small quantity of oil, which was used for lubrication of the drilling outfit. This statement could not be verified, but it is highly probable, as overlying shales in the same block, and in Blocks 91, 92, and 93 there are many exposures of bituminous shales, presumably overlying the sandstone. These shales grade from sandy to finely foliated.

In a well put down to a depth of 300 ft. on Sec. 21, Block 92, T. 6, the formation passed through, as given me by the driller, consisted of 90 ft. of soft earthy gypsum; from 90 to 100 ft., banded calcareous shale; from 100 to 175 ft., the same but softer; from 175 to 300 ft., sandy limestone. At a depth of 90 ft. a smell of gas was noticed, increasing with depth. The hole was dry at time of drilling, and when the gas-bearing stratum had been perforated some distance, the driller, out of curiosity, dropped some lighted waste into the hole, with an explosion of gas as the result. This could not be verified, as rain-water had filled the well to within 50 ft. of the surface, and although the drillings had a characteristic bituminous odor no gas was escaping.

Lone Man mountain, on Sec. 1, Block 92, appears to be capped with fine gray dolomite, and the same is true of a line of hills to the northeast of C. Tinnin's ranch on Sec. 12 in Block 93. All of these hills are surrounded and underlain by gypsum, and there appears to be a regular line of caves along this belt, indicating a line of probable structural weakness, which afforded vents for the gases and solutions already mentioned. As shown by the accompanying figure, these hills have the appearance of islands in a gypsum lake or sea, and in going into one of the largest caves, on Sec. 17, in Block 96, a lateral distance of about 1000 ft., the descent amounted to about 225 ft. (barometric reading). I noticed in this cave more or less subsidence of the strata, so that the apparent course and dip could not be depended upon, although the rock appeared to be massive and solid. I partly account for this by the fact that there seems to have been a general degradation of all these gypsum areas, as evidenced by the fact that the mouths of the caves, now lower than the surrounding ground (permitting the inflow of torrential rain-water, which is characteristic of the Southwest) were undoubtedly originally higher, as indicated by the grade of the arroyos leading therefrom, permitting any water issuing therefrom to travel away from the cave, down the slope. At this time, owing to subsidence of the cave mouths (in some instances) fresh waters are finding their way into the caves, and blocking them with all kinds of débris.

I am drawing particular attention to this point to emphasize the fact that many [illegible] of the [illegible] may be [illegible] of the [illegible] gypsum, [illegible] the [illegible] indicated by the caves. Such depressions should be carefully studied so as to avoid [illegible] anticlinal [illegible] and taken for anticlinal folds, and the corresponding depressions for synclines.

It is unnecessary in this paper to outline the various folds in the field. One long anticline runs between Townships 5 and 6, and another about due south from San Martine on the T. & P. railroad. The latter has been carefully studied and worked out by a Mr. Everest of Oklahoma City. A particularly prominent exposure of an anticline exists in a place known as Hackberry Mott, to the southeast of Rustler draw, about on the line of Block 110 and 42. This is overlain by fine gray magnesian limestone, and underlain by sandstone. Another general line of folding is indicated by the main course of Cottonwood draw, and about in the middle of Block 59, T. 5, it turns to the southeast. It is quite possible that portions of Cottonwood draw indicate a line of structural weakness, which may have gone to the extent of faulting, but this will have to be determined by systematic drilling.

DOLOMITE-CAPPED HILLS SURROUNDED AND UNDERLAIN BY GYPSUM NEAR C. TINNIN'S RANCH.

Throughout this region wells have been sunk for the purpose of finding water, and almost invariably the owners declare that more or less oil was found at a short distance from the surface. From my personal observation I am only able to say that shallow oil of excellent quality for lubricating purposes has been opened on and near Sec. 16 and 17, Block 59, the oil-sand having been found at depths varying from 130 to 325 ft. On or about Sec. 17, in this block, the Texas company has put down two or three wells, but profound secrecy is maintained by this concern, and no logs could be procured. One well which has been capped and plugged showed a good pressure of gas, escaping from the sleeve. The derrick over this well was burned some time since, but the cause of the conflagration can only be surmised. It is commonly reported that it was burning gas. The drilling tools were warped and much bent, and it is hardly possible that the burning derrick material would have caused such heat. On the S.W. ¼ of Sec. 44, Block 55, the Corsicana company is sinking a well and is now down over 1100 ft. At a depth of 243 ft. a 3-ft. streak of oil-sand was found, and from that depth onward it has been drilling through blue clay and shale, showing occasional streaks with globules of oil in the sludge.

Attention should be called to the large beds of sulphur adjacent to the Texas company's wells, Rustler springs, and particularly at Maverick springs, where it is a well known fact that inflammable gas was found, and was used for domestic and other purposes while the sulphur deposit was being worked some years ago.

The enormous area of this field which shows outcrops of bituminous shales and limerock, with underlying beds of sandstone, leads me to believe there are vast reservoirs favorable to the accumulation of oil, a portion of which has escaped and impregnated the overlying strata, as indicated in shallow wells, such oil in certain favorable places constituting an actual commercial supply (for lubrication). I understand that the oil so far brought to the surface has a paraffine base, and seems to have undergone a natural distillation, thereby losing the bulk of the lighter and highly inflammable constituents.

Surface water highly charged with gypsum can be found almost anywhere in the district, in the gypsum belt, at comparatively shallow depths, ranging from 30 to 80 ft., and artesian water has been proved around the town of Toyah at depths of 625 to 750 ft. One of the wells on the north side of this town penetrated a strata which gave off a large volume of inflammable gas, under high pressure, but unfortunately the well was continued into the artesian strata, with the result that as a source of gas the well is a failure. This water is charged with sulphuretted hydrogen, which on reaching the surface deposits sulphur.

Throughout the gypsum belt there is a strong growth of juniper (locally called cedar), the cost of which need not exceed $2.50 per cord delivered at the rig, including stumpage to land owners. In portions of the country under review, away from this timbered zone, oil will have to be imported for fuel, unless wells now being drilled are in a position to furnish it. The price of this commodity will of course be governed by distance from railroad, wagon haul, etc. The indications are that oil in small quantities can be developed from a depth of 140 ft. and deeper, with a probability of gas and deeper oil at depth of from 1600 to 2500 ft., according to locality. The purpose is to reach either the upper Carboniferous strata, underlying the Delaware mountain formation, or a strata overlying same favorable to the accumulation of oil.

Should oil be developed in this field in commercial quantity there is an extensive and ready market for its disposal. The nearest producing fields are situated at distances of from 800 to 1000 miles, north, east, and west, so that with Toyah as a centre, it would dominate a region of that diameter, requiring probably a supply of 1,000,000 to to 150,000,000 bbl. per annum. At a price of even $1 to $1.25 per barrel this crude oil would be in great demand by all classes of industry. I believe the field offers excellent opportunities for legitimate drilling operations, with every indication of proving a large and profitable business.

Rainfall in Nicaragua

The amount and distribution of rainfall bear so directly upon mining, that the following figures, presented through the courtesy of Henry B. Kaeding, general manager for the Siempre Viva Mining Co., will be read with interest. They give the rainfall at the Siempre Viva mine in eastern Nicaragua since 1904. They may be compared with the average rainfall at Panama, which in the Chagres valley is 100 inches per year, according to Col. G. W. Goethals. Figures below are in inches:

	1904.	1905.	1906.	1907.	1908.	1909.	1910.	1911.

July	1,590,357	1,800,000

Kildonan Placers in Scotland

Once every ten years the gold placers of Kildonan, in the wild northwest of Scotland, come before the public and the daily papers revel in sensational or sentimental paragraphs. For the last three or four months a Mr. Heath, who gained his experience at Klondyke, has been thoroughly sampling the gravels in various streams tributing to Helmsdale in Sutherland estate, of which the Kildonan is the most important, and the papers of London have made frequent reference to these fields. Tradition has it that gold was discovered as early as the year 1245, but no authentic record is extant of any work being done. In 1840, it is stated, a nugget weighing 1½ oz. was found in the Kildonan stream. A rush was made to the district in November 1868, and for a year or so 400 men were occupied. During this time the production of gold worth £3000 was reported officially, but as the law imposed a 10% royalty there is good reason to believe that the production was really much greater. A competent authority put the actual figures at £12,000. At about the same time gold gravel was found some ten miles to the southwest in two streams that run into Loch Brora; the work, however, interfered so much with sheep farming that the licenses were suspended in 1870.

The Kildonan district consists of moorland and heather-clad hills, with extensive bogs at the sources of the streams. The valleys are mostly narrow and straight, so that there are few alluvial flats of any notable size. The rocks are granites and metamorphic schists of varying character, and over them are thick deposits of glacial drift which are overlain in their turn by peat beds. The gold is found as small grains in the beds of the streams and in the gravel banks. It is most abundant in the coarse gravel and in the crevices of the upturned edges of the schists, across the strike of which the streams run, but it appears to be also disseminated throughout the drift. The heaviest nugget ever found weighed 2 oz. 17 dwt. The richest deposits so far known were in Goldburn, where several specks may still be obtained from every pan. The source of the gold has not been identified; it is doubtless to be sought in the quartz veins which are found in the schists and in the granite at the contact with the schist. Several such veins are known, but apparently no indication of the presence of gold has been recorded.

Prince William Sound Copper Mines

The latest reports from various copper properties in Prince William Sound indicate that mining is active. Mining operations at Latouche are well under way, 70 men being employed; the Beatson is shipping at the rate of 1000 tons of ore per month. Plans for building a concentrator are being discussed. Diamond-drills are being used in testing the ground below present workings and are said to be developing copper ore averaging over 6%. The Barrack property adjoining the Beatson has been bonded by the Alaska Syndicate and a crew of men is at work there. On Fidalgo bay, 17 miles south of Ellamar, two orebodies have been found. Over 1000 ft. of tunnel has been completed, and this property will soon join the others as a steady shipper of high-grade copper ore to Tacoma. It is said it will rival the Beatson in total tonnage. W. H. Dickey, of the Three Man Mining Co. on Landlock bay, is said to have 20,000 tons of 10% ore. Mr. Dickey has just opened the Mason-Gleason property, also on Fidalgo bay. Knight's Island Copper Co. is developing a large body of concentrating ore. The orebody at present developed is 700 ft. along the strike of the lens and over 120 ft. wide.

During the past year development on Prince William Sound has been somewhat backward, owing to the discovery of gold quartz in the Copper River country which has attracted all the prospectors and miners from that section to the interior. Mines on tide-water, however, are sure to develop in time.

Quicksilver in the United States in 1910

Of the 19 mines producing quicksilver in the United States in 1910, 15 are in California, 2 in Nevada, and 2 in Texas, according to H. D. McCaskey, of the U. S. Geological Survey. The production in 1910 was 20,601 flasks of 75 lb. each. At the average domestic price at San Francisco, $46.51 a flask, the value was $958,153. As compared with the production of 1909, which was 21,075 flasks, valued at $957,859, this shows a decrease in quantity of 474 flasks, but an increase in value of $294. Although the production of California increased in 1910, the output from Oregon decreased to nothing, as that of Arizona did in 1909, the small Nevada production fell off considerably, and the output from Texas decreased. In no State, except possibly in Nevada, can an increased output be expected for 1911, the present outlook being for a total production for the United States not exceeding 20,000 flasks.

A good domestic demand for quicksilver was noted throughout 1910. The principal uses are for gold milling and placer mining, for the manufacture of vermilion, fulminates, physical instruments, and drugs, and for lighting. The use of quicksilver in making the fulminate of percussion caps for igniting powder is increasing in importance probably more than any other use. The consumption for all purposes in 1910 was somewhat greater than the domestic production, stocks decreased to a small supply, and the condition of the trade within the United States was generally good.

Producers reported the mining of 132,813 tons of new ore available for treatment in the United States in 1910 and the treatment during the year of 123,562 tons of ore, including small amounts of crude ore concentrated before reduction.

In California 115,306 short tons of crude ore was treated, producing 15,825 flasks of quicksilver, indicating an average recovery in metal of 0.5% of the ore treated, or 10.3 lb. per ton. In addition, old material treated produced 1386 flasks of quicksilver. In 1909 a total of 144,989 tons of ore treated in California yielded an average recovery of metal of 0.4%, or 8 lb. of quicksilver per ton. These figures indicate average gross returns per ton of $6.39 in 1910 and of $4.85 in 1909, and show that in quicksilver production on a considerable scale the total costs are low. In Texas 8221 tons of ore was treated in 1910, yielding an average of 1.5% of metal, or 30.3 lb. of quicksilver per ton, against 9107 tons in 1909, yielding 1.7% or 34.5 lb. of metal per ton. In Nevada, about 35 tons of ore was treated in 1910, yielding 7.5%, or 150 lb. of quicksilver per ton. In the entire United States, 123,562 short tons of crude ore was treated in 1910, yielding an average of 0.6% of quicksilver, or 11.7 lb. per ton, with a gross value of $7.26. In the preceding year, 154,502 tons yielded an average recovery of 0.5%, or 10 lb. of metal per ton, valued at $6.09.

The production in California is almost wholly from shaft furnaces of Scott, Litchfield, and related types. The Texas ores are all treated in Scott furnaces. The Nevada production has so far been entirely from retorts, these being less expensive than shaft furnaces, better suited for high-grade ores, and frequently used at new mines where there is usually some rich ore. These retorts, however, are a menace to the health of the workmen. As is well known, cinnabar, the sulphide of mercury, is the chief ore of the metal, and recovery is accomplished by volatilization of the quicksilver from the ore by heat and condensation of the mercury vapors and condensers. Fluxes are not required, as in the metallurgical treatment by smelting of most other metals, and frequently the ore itself carries the equivalent of fuel in the form of pyrite which gives off considerable heat in oxidation.

The world's production of quicksilver in 1910 was 3399 metric tons of 2204.6 lb. each, against 3304 tons in 1909, 3296 tons in 1908, and 3307 tons in 1907. Spain is the largest producer, furnishing nearly a third of the total world's supply from the famous Almaden mines. The

United States, Austria-Hungary, and Italy have in turn held second-place, this country ranking third in 1910. The imports of quicksilver for domestic production are now nominal, having been in 1910 only 667 lb., valued at $381, although the values of the imports in the preceding three years varied from $6000 to $8000. The exports of quicksilver in 1910 were 144,237 lb., valued at $91,077, against 510,141 lb., valued at $266,243, in 1909. The chief market is now Canada, followed by Mexico. Prices of quicksilver in 1910 averaged $46.51 a flask of 75 lb. in San Francisco for domestic use, and $44.51 for export.

Copper and Pig Iron

The following tabulation shows the yearly production and prices of copper and pig iron since 1890, the percentages of increase in production and prices for the first decade being given in five-year periods. They were compiled by I. M. Taylor & Co. of New York, whose circular says:

"While no absolute relation can be proved between production of copper and copper prices and pig iron production and prices, figures showing comparisons between the two metals present possibilities of interesting deductions. In a general way the use of both metals will without doubt tend to increase conformably to the growth of the country. Sporadic changes in the ratio of supply and demand in the case of either would at any time naturally affect individually the price of either metal. Iron is now being used so generally in all industries that it is difficult to foresee any new uses which would create an unusual demand for it, while, on the other hand, new uses for copper are being found daily, and at the same time the probability that the electrification of the railroads will proceed rapidly within the next few years opens up an enormous new demand for the red metal. Again, while ore reserves for pig iron are practically unlimited, no supplies of copper ore other than those now being worked or developed are known to exist in the United States.

During the two decades the average annual increase in the production of copper was 8.4%, as against 7.8% increase in pig iron. The fluctuation in the amount of pig iron produced is much the more irregular of the two, the readier response to demand being due to the greater facility with which production may be curtailed.

It will be noted by a glance at the price columns that in the main the relation between the two has been close. The high and low for each were made in the same year, and since 1904 the fluctuation in each has been almost identical. The fact that the prices of both have remained at a comparatively low average level since the panic of 1907 indicates that the country's producing capacity, which had been expanded to meet the boom demands of 1906 and 1907 has never been tested during the past three and a half years. Since that boom capacity was attained the country has grown 10%, and if our industries were operating at normal now, the demand would undoubtedly exceed the capacity. We believe that fundamental conditions have been restored by the past three years of economy and that next year should be one of general business expansion with consequent advancing metal prices."

Chichagof District, Alaska

By V. H. Wilhelm

In the last few years many small but high-grade quartz mining districts have been developed in Alaska, and men at Nome, Seward, Dawson, Valdez, and Fairbanks are all turning their attention in that direction. This form of mining follows naturally in the wake of the placers, which in many cases have led directly to the discovery of the quartz. One of the most remarkable of the newer districts is the Chichagof, where a camp has been established on Klag bay, Chichagof island, sixty-five miles northwest of Sitka. The original discovery was made by Indians in 1906. Active operations began with the gathering of high-grade boulders and float from the bed of the creek below the vein. Enough ore was collected in this way to pay for the first mill, which consisted of two Hendy 2-stamp triple-discharge batteries. The vein is in graywacke and slate, in a shear zone, and runs southeasterly, with an 80-degree dip to the south. The ore occurs in shoots averaging from 8 to 14 ft. wide, the quartz being ribboned with slate. Pyrite and much free gold are found, with a great deal of graphite and a little arsenopyrite.

At present there are two mills operating in the district. The original location is occupied by the Chichagof Mining Co., which has a 10-stamp mill with Wilfley tables. The company includes Messrs. Rust, Bratnober, and DeGraff, and the Jarvis estate. Much high-grade ore from the upper levels has been shipped to Tacoma. The average value of the mill ore is stated to be $17 per ton, and 60% of the gold is caught on the plates. Outside amalgamation only is attempted. The vein is tapped at the mill level by a 900-ft. adit giving 230 ft. of backs.

The other mill is operated by the Golden Gate Co., controlled by W. P. Mills. It is on the extension of the shear-zone, and includes 10 stamps, with Pindar tables. Ore is supplied by a 2500-ft. aerial gravity tramway, and comes from a shoot averaging 4 ft. in width. A second shoot which averages 7 ft., occurs 200 ft. beyond the first, and a drift is now being driven to tap this second shoot at a depth of 160 ft. The mine ore averages $17 per ton.

In both mills salt water is used during the dry season, and is found to possess both advantages and disadvantages. It keeps the amalgam soft and makes amalgamation easy for the heavy sulphide ore, but it also increases the wear on screens, boss-heads, and stems. Both mills are driven by electricity supplied by a hydro-electric power-plant five miles distant. Water for this plant is drawn through a 200-ft. tunnel from a lake which is tapped below the frost level and supplies power all the year round. The district has many promising prospects. Many small but high-grade stringers have been discovered, and high-grade float on the beach is of common occurrence. Most of the orebodies are in slate. Prospecting is generally done by boat along the shores or by exploring the creek beds, the heavy underbrush making travel difficult on the hillsides. Alaska suffers from lack of trails, and, except when accessible by water, few veins have been opened. Discovery of a few rich veins such as these will open the country rapidly.

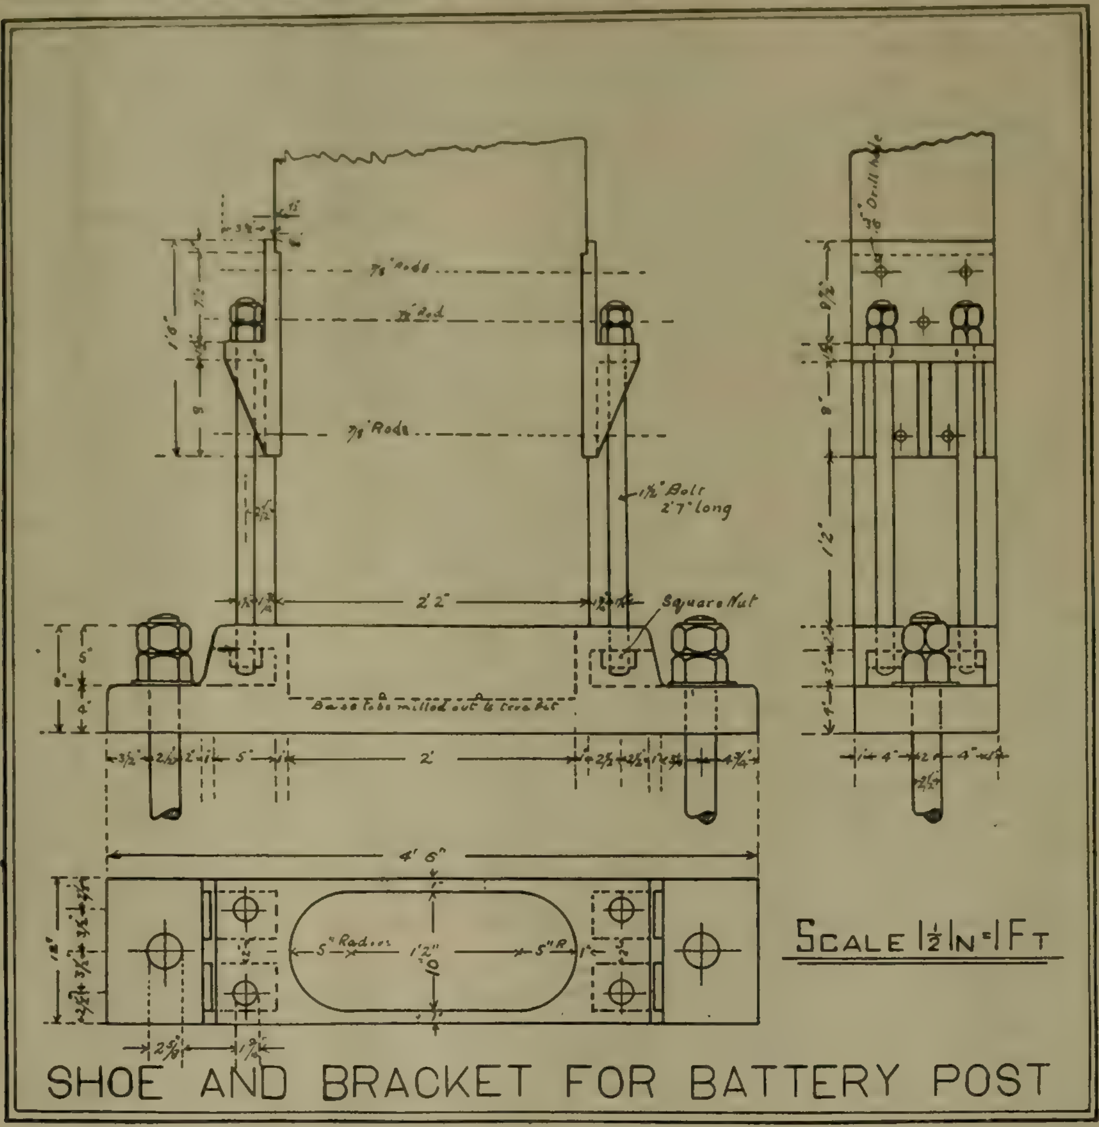
Securing Battery Posts

By Francis W. Sewell.

Of the many different contrivances for securing battery posts to the concrete foundation block, the method, described below, will commend itself to constructing engineers, on account of its solidity, simplicity, and strength. The arrangement was designed for use in the battery of the Guanajuato Cons. M. & M. Co. and has proved to possess material advantages over many other contrivances. It has been used in the construction of the Zacatecas M. & M. Co.'s mill, where the author had through the courtesy of Parrish McDonald, an opportunity to obtain the following details.



SHOE AND BRACKET FOR BATTERY POST

The shoe is of cast iron and weighs 860 lb. It has a bearing surface on the concrete 4 ft. 6 in. by 1 ft., thus distributing the strain of the frame over a considerable area. The shoe is secured to the foundation block by two 2½-in. rods, each 5 ft. long, threaded at both ends. The threaded portions are of enlarged cross-section, so the diameter of the base of the thread is not less than that of the remainder of the rod. The lower ends of the rod pass through broad square cast-iron washers, embedded in concrete, and are secured thereto by square nuts. Hexagonal nuts are used at the top end to hold down the shoe; lock nuts are shown in the accompanying sketch, but these are not necessary.

The shoe has a cavity cast in it, 2 ft. long by 10 in. wide by 6 in. deep, with rounded ends, into which the foot of the battery post fits. The bottom of this cavity is milled so as to give an even bearing surface to the post. At each end of this shoe are cast suitable projections, bored vertically with 1⅝-in. holes to receive the ends of 1½-in. bolts. Iron brackets, which weigh about 100 lb. each, are recessed into 12-in. faces of the posts, and secured in place by five ⅞-in. rods, which pass through the post from one bracket to the other. These rods are threaded at both ends and nuts hold the brackets firmly in position. Passing vertically downward from each bracket to its respective end of the shoe are two rods, already mentioned, with square nuts to attach them to the shoe and hexagonal nuts to attach them to the bracket. The lowest part of the bracket is 1 ft. 2 in. above the top of the shoe, so it will be seen that once the post is set in position, with all the nuts tightly screwed down, there is very little chance for any movement. With the exception of lower nuts of the 2½-in. rods holding down the shoe, all the nuts are readily accessible.

In the erection of the battery the cavity is half filled with oil and the foot of the post is cut slightly larger than the cavity, the point being cut to just enter. Some specially long rods are passed up through the brackets from the shoe, and fitted with nuts, which on being screwed down, force the post into the cavity. This action is aided by blows with heavy hammers on the top of the post. The oil is forced into the end of the grain of the wood.—*Inf. y Mem. del Inst. Mexicano de Min. y Metalurgia.*

A Park City Merger

One of the important recent developments at Park City, Utah, was the announcement that stockholders' meetings of the Ontario company will be held October 10 and of the Daly September 20 to consider a merger proposal. The ownership of these two companies has always been to a large extent identical, and economy in operation is urged as the principal reason for combining. As a matter of fact, however, the combination of these two companies is generally regarded as the first step in a far more comprehensive consolidation. The Ontario is the pioneer mine in Park City, with a record of having paid $13,692,500 dividends. While its orebodies have greatly diminished in value, it still holds a strategic position on account of its ownership with the Daly, of the Ontario drain adits, without which some of the leading mines of the district cannot be operated at depth. It is proposed to form a new company of 300,000 shares, par $5, incorporated under the Nevada law. This company will exchange share for share Ontario stock, and two shares of Daly for one of the new corporation. This will leave 75,000 shares and over $135,000 cash in the treasury, available for use in systematic development work of virgin ground, of which the two companies possess a large acreage. They also own a coal mine, a light and power company, a water company, and other properties. They now have large holdings of stock in the Thompson-Quincy and Naildriver companies, which own adjoining properties needing the extension of the drainage system for deep development. It would not surprise Park City people to see these two included in a later merger, as well as the Daly West, with which there is a close connection. For a long time the Daly West, Ontario, and Daly employed the same general manager, and the Ontario drainage adit extends into Daly West ground, affording also an outlet for ore. Whether Daly-Judge could be drawn into a great merger later is a question, although this company needs the drainage adit for deep development. It recently entered into a contract whereby the adit will be extended to its ground, on a rental and royalty basis, drawing off the water and affording an outlet. This accomplished, and with the Snake Creek adit approaching the other end of its holdings, the Daly-Judge is now in a comparatively independent position. Nevertheless, advances made to this company and to the Silver King Coalition not long ago looking toward a consolidation of all the big producers in the district will probably be soon renewed. The plan, which has been under consideration by leading interests in the district for some time, has its basis in the fact that Park City is a deep-mine camp, in which operations are expensive, and that a consolidation would mean economy of operation and far greater possibilities in the way of new development. The Daly-Judge, as a result of its contract for the extension of the Ontario adit, is now beginning the development of its lower levels. The water is fairly well drained, and the main adit is now within 300 ft. of the Daly-Judge lines. Though the Daly West, connection with the 2300-ft. level was made, and the main adit will open the 2500-ft. level. The shaft is down 1600 feet.

Fire-Damp in Gold Mines

At the Simmer Deep gold mine several natives were recently burned by an explosion 3000 ft. from the surface. The place was examined two days later by the shift boss with a naked light, when on putting the light well up in the hanging wall a second explosion took place by which he also was burned about the face. Every indication points to fire-damp (CH_4) as having been the cause of the explosion, but this has been so rare an occurrence in the annals of Rand mining that some doubt existed at first whether the explosion could possibly be attributed to fire-damp. There cannot possibly be now any doubt as to the identity of the gas. It seems that a drift at over 3000 ft. from the surface had reached a break in the strata and being unventilated, afforded every facility for the accumulation of gas. It may be also pointed out that at the Anglo Deep gold mine in the same neighborhood a bore-hole put down in the foot-wall of the reef at 4000-ft. depth from the surface produced considerable quantities of gas, so much so that the bore-hole had to be plugged to put a stop to its further escape. The explanation for the generation of this gas is the fact that below the Main Reef series there occurs a huge thickness of shale, which on being tapped, gives off this gas. The break at the Simmer Deep extending down into this shale would act in a similar manner to the bore-hole at the Anglo Deep, and thus provide a means for the escape of the gas which, occurring as it did at the face of an idle unventilated drift, would present the precise condition necessary for such an accumulation of fire-damp. These are the only two reliable instances recorded of the occurrence of fire-damp on the Rand, but in the lead mines of the Derbyshire where similar beds of shale occur, the presence of fire-damp has been frequently noted.

July Petroleum Production

Petroleum production in California in July, according to the *California Oil World,* amounted to 6,663,325 bbl., an increase of 261,021 over June. This is at the rate of 79,959,900 bbl. per annum. Not included in this estimate are 429,200 bbl. burned in the fields as fuel, which would bring the total production for July up to 7,092,525. The following table shows the production by districts:

San Joaquin:	July Production.	Daily Average.
Coalinga	1,577,131	50,875.19
Kern River	1,044,379	33,689.64
McKittrick	450,062	14,518.13
Maricopa	426,366	13,753.74
Midway	1,773,105	57,196.93
Totals	5,271,043	170,033.64
Coast:		
Santa Maria-Lompoc	429,112	13,842.26
Summerland	5,850	188.71
Totals	434,962	14,030.97
Southern:		
Salt Lake-Sherman	228,680	7,376.77
Fullerton	566,796	18,283.74
Whittier-Coyote	77,390	2,496.45
Los Angeles City	36,800	1,187.09
Ventura county	34,714	1,119.80
Newhall	12,940	417.41
Totals	957,320	30,881.26

During the month 55 wells were completed; producing wells active, 5114; idle, 301; drilling, 891; new rigs, 42; abandoned, 3.

Queensland's gold yield for June, according to the *Queensland Government Mining Journal,* was 34,018 oz. fine, of the value of £144,499. For the corresponding month of last year the return was 41,637, of the value of £176,863; so that there was for June of this year a comparative decline of 7619 oz. in weight and £32,364 in value. The largest decrease was at Charters Towers, where there was a falling off amounting to 4244 oz. There were also decreases—at Gympie, of 1226 oz.; at Mount Morgan, of 2700 oz.; at Ravenswood, of 261 oz.; and at Croydon, of 240 oz. From copper ores at Cloncurry, however, 1223 oz. of gold was obtained, as against nothing for the corresponding month of 1910; while there were also small improvements in the outputs from the Gladstone and Rockhampton fields. The return for the first six months of this year was 184,641 oz., of the value of £784,305, a decrease of 33,798 oz. in weight and £143,564 in value compared with the yield for the corresponding period of last year. The dividends declared by gold mining companies for the month of June totaled £77,596.

Discussion

Readers of the MINING AND SCIENTIFIC PRESS are invited to use this department for the discussion of technical and other matters pertaining to mining and metallurgy. The Editor welcomes the expression of views contrary to his own, believing that careful criticism is more valuable than casual compliment. Insertion of any contribution is determined by its probable interest to the readers of this journal.

Life of the Rand

The Editor:

Sir—The statement made by the Minister of Finance in introducing the budget for the current year, that the gold resources of the Rand were estimated at £2,000,000,000, has attracted some attention, owing principally to the fact that it is far in excess of any estimate made by any other qualified authority. It is to be assumed that this estimate was made by the Mines Department, in which case its reliability ought not to be doubted in the face of the facilities possessed by that department for the framing of such an estimate.

Even in the present stage of the Rand's existence, after a duration of 25 years, the task of arriving at an approximate estimate of its life is by no means an easy one, owing to the number of unknown and uncertain factors, but in the face of previous estimates, that of the Minister of Finance appears to be liberal. For instance, John Hays Hammond many years ago made an estimate that the future resources amounted to £800,000,000. In 1902 Hatch & Leggett estimated the future yield as £1,000,000,000, fixing the depth limit as at 6000 ft., so that even today, nine years later, the Mines Department apparently doubles the estimate, but nothing is stated as to the depth limit upon which the latest estimate is founded.

Supposing that the latest estimate made by the Minister of Finance is approximately correct, then comes the difficulty of reducing the estimate to the number of years' output it may be calculated to represent. In some quarters it is often represented that the Rand has reached its zenith and may soon be expected to show a declining output. A little reflection will show that there is still an additional area of the Rand, more particularly in the Far East section, to be made producing before the maximum producing capabilities of the Rand may be considered as attained, and several years must elapse before this position is approximately reached. Even when the zenith has been reached, it will be many years before a decline sets in, and the later years of its life will be somewhat like its former, so that any attempt to calculate the future life of the Rand based on the latest figures must fix it at a minimum of 80 years at least.

Considering that the latest estimate is made under Government auspices, it will carry with it the conviction of erring on the conservative side, so that there is every justification for regarding the future life of the Rand as a long one. Of late several of the deeper mines have shown an improving grade in the lower levels, and this has tended to dissipate the view so long held that as greater depths were reached the grade would consistently decline. Probably the more correct view is that even beyond the greatest depth yet attained, there will be varying grades of value in the ore just as there has been in the first mile from the outcrop, and that the limits to deep mining will be governed by the value of the reefs more than by the usual difficulties attendant on deep mining in other parts of the world. It will therefore be seen that there are many elements of uncertainty entering into the question of calculating the future life of the Rand and that as time goes on the estimate will have to be frequently revised, just the same as is found necessary in estimating the life of individual mines on the Rand. It is always found that gold mines on the Rand last for a much longer period than previous estimates of their life would seem to indicate, and, seeing that the Rand consists of an agglomeration of small mining properties, no doubt a similar experience will await it, so that its life may also be expected to continue long after it has reached the estimated period allowed it. According to the Minister of Finance, even with the present output continuing throughout its existence, its life must be calculated at nearly seventy years, but mining areas here have a habit of far exceeding their estimates, and the resources of the Rand south of the outcrop are so large and difficult to determine that it is probable that the Rand will continue to produce quite a respectable output of the precious metal long after the two thousand millions sterling resources as estimated have been mined and crushed.

ROWLAND GASCOYNE.

Johannesburg, July 1.

Inadequacy of Language

The Editor:

Sir—On returning from an examination, with more than one reference to 'values' in the rough copy of my report, I find in your issue of July 15 that this convenient word has again been censured by an editor's pen. The chief objection to it appears to be that it is applied in some cases where the cost of extraction at the time of writing equals or exceeds the worth of the contained metals. An ore, therefore, with gold and silver worth $10 per ton has no value if it costs $10 to extract; in other words, values are non-existent if they cannot be taken out at a profit. But as in a mine report, description of the deposit precedes the question of treatment methods and costs, some word or expression is needed to denote the theoretic value of the ore at different points and without immediate reference to extraction possibilities. The ore must be considered first and its difficulties later.

In the following typical sentence, "From this point to the end of the level the values are low and would not pay to treat unless the mill capacity is increased.", I beg to suggest that the word 'values' is used correctly, as, although the vein material cannot be treated profitably at the time of writing, it can be when the costs are lowered by treatment of a larger tonnage, and nothing alters the fact that metals with a market value occur in the vein. The sentence might be written, "From this point the ore is low grade and would not pay", etc., but if an ore is the profitable part of a deposit, the word is incorrectly used, as the ore, according to this definition, does not exist until it is made profitable by enlarging the mill. In some cases an alternative might be, "From this point the gold, silver, and copper contents of the vein are too small to treat," etc., but this forms one of the awkwardly long expressions to which you refer in your editorial as the result of an attempt to be accurate.

A term to denote the content of a deposit at different points must, of necessity, recur constantly in the average mining report. That it does so to the detriment of a literary style is certain, but the subject matter does not lend itself to faultless rhetoric, and when an engineer has stated his case plainly and without grammatical errors, he may be pardoned for the occasional reiteration of an expression. If the word 'values' conveys its meaning to the reader, it can be assumed to be suitable, and can therefore be accepted in the same way that many other words have been accepted by the profession and standardized by use. As no practical substitute has been suggested, 'values', when referring to an ore deposit, might be standardized to mean the worth of the marketable contents for a given weight or measurement and without consideration of the possible profit or loss resulting from mining, treatment, or shipping costs.

E. A. SMITH.

Mexico City, July 31.

For the first six months of 1911 the cost of making copper by the Old Dominion was 8½c., excluding construction, and 9c. flat, including construction, everything having been charged against copper costs. The Old Dominion Co. received an average of 12.17c. for the six months on a production of about 14,000,000 lb., which would indicate that the Old Dominion Co. of New Jersey earned about $450,000 net, and the United Globe earned $60,000 net, or a total of $510,000.

Concentrates

Most of these are in reply to questions received by mail. Our readers are invited to ask questions and give information dealing with the practice of mining, milling, and smelting.

MANILA ROPE of 2-in. diameter has an ultimate strength of 28,500 lb. For hoisting, the working load should be 1600 lb., and the hoisting sheave should have a diameter of 20 inches.

LACK OF CAPITAL to carry good plans to a conclusion often causes the failure of mining operations, but poor management is quite as often the cause. Only the best mines pay with poor management.

WHITE ARSENIC, the oxide, is the only form in which arsenic is produced in the United States. Most of the arsenic imported, however, comes as the sulphide. It is brought from Canada, Europe, and Mexico in considerable quantities.

CONCENTRATES can not undertake to express an opinion as to the probable presence or absence of an orebody in a given situation, even when sketches and details of the occurrence are submitted. Such matters require personal examination by a competent engineer, and any other expression of opinion would be guesswork.

ANNUAL LABOR must be done within the calendar year succeeding that in which the location was made. Thus a claim located at 1 a.m. on the morning of January 1, 1910, needs no annual labor during 1910, but does require $100 worth of work before expiration of 1911. It should not be forgotten, however, that in some States location work is required within a limited time.

WATER-POWER costs for development from $34 to $287 per horse-power, depending on many different conditions. For example, 15,500 net horse-power, with complete electric equipment and transmission, cost $225.80 per unit on the Chicago drainage canal, where the fall is 28 ft. The canal itself cost many millions. At Delta, Pennsylvania, 550 hp. cost at the rate of $54, the fall being 42 ft. and the transmission 5 miles. No general figure can be safely quoted.

STEEL AND PIG IRON production has been rapidly increasing in the United States, but still amounts to considerably less than half the total of the world's production. This in 1909 ws 53,499,974 metric tons steel, that of the United States being 24,338,302. In pig iron the corresponding figures were 61,217,064 and 26,108,199 tons, respectively. Pennsylvania is much the largest producer among the States, having 10,918,824 tons of pig and 12,245,889 of steel to its credit. Alabama produced 1,763,617 tons of pig iron and much less steel.

WHITEWASH is a preparation of slacked lime or of whiting, and some sizing material. Common whitewash may be prepared according to the following recipe: Slake lime with boiling water in a tight vessel, stirring briskly. Add 2 lb. sulphate of zinc and one of common salt for every $\frac{1}{2}$ bushel of lime. If a pint of linseed oil be added to each gallon of whitewash after slacking, it will add to the durability, especially for exterior work. Flaking can not be entirely prevented, but the sulphate of zinc and salt help. Use two coats and don't expect the job to last forever.

TUNGSTITE is tungsten trioxide and contains 79.3% of tungsten. It occurs usually as a pulverulent yellow or yellowish green earth and rarely in sulphur-yellow crystals which are orthorhombic. It is found with wolframite, the more common source of tungsten, and has been known from Cumberland and Cornwall in England, from Limoges in France, from Monroe, Connecticut, and from North Carolina. Recently it has been found in California at the Burlington mine, Forbestown. Here it occurs with black sand in vein matter next gold-bearing quartz. The commercial importance of the find has not been determined.

ORDINARY AIR consists chiefly of a mixture of two gases, oxygen and nitrogen. Oxygen is life supporting; in the lungs it combines with substances in the blood and forms carbon dioxide, a suffocating gas, which is exhaled in the breath. This union produces heat and maintains the temperature of the body. The nitrogen in the air is not absorbed nor changed in the lungs, and may be breathed over and over again. Ordinary air contains oxygen, nitrogen, and carbon dioxide, in the following proportions by volume: oxygen, 20.94%; nitrogen (and argon), 79.03; carbon dioxide, 0.03.

SECOND-FEET or sec.-ft. is a term much used in discussing the 'run-off' of an area. It is an abbreviation for cubic foot per second, and is the rate of discharge of water flowing in a stream one foot wide, one foot deep, at the rate of one foot per second. It equals 7.48 United States gallons per second. In making calculations, one second-foot falling 8.8 ft. equals 1 hp., and $1\frac{1}{3}$ hp. equals one kilowatt. To determine the horse-power on a wheel realizing 80% of its theoretical power, the following formula is used:

$$\frac{\text{Second-feet} \times \text{fall in feet}}{11} \quad \text{net horse-power}$$

MANGANESE ORE is sold on a sliding scale, the price per unit being proportional to the richness. For example, recent London quotations on 50% Indian or Brazilian ore were $9\frac{1}{4}$ to $9\frac{1}{2}$d. per unit, while for 45% ore the quotation was $8\frac{1}{2}$d. Caucasian ore sells for less, the 50% being quoted the same day at $7\frac{3}{4}$d. London prices are based on 8 to 10% silica, with a penalty for excess. Ores are bought in Chicago on a similar basis, 49% ore and over being paid for at 30c. per unit, 8% silica being allowed and 0.25% phosphorus. Iron is paid for in addition at 6c. per unit. In both cases prices are based on tons of 2240 pounds.

IN BREATHING ORDINARY air a man consumes from 10 to 35% of the oxygen that passes into his lungs: the rest he exhales with the nitrogen he inhaled and the carbon dioxide produced in his lungs. The exhaled breath contains 2.6 to 6.6% of the suffocating gas carbon dioxide, or an average of about 4%. The percentage does not change much, whether the air breathed contains a high or a low percentage of oxygen, so long as a man breathes freely. But when a man breathes air that contains as much as 5% of carbon dioxide, even if it contains a high percentage of oxygen also, he begins to breathe with effort, his head aches, he feels dizzy, and he may have pains in the chest. The same difficulty in breathing may be felt when a man breathes air containing as little as 14% of oxygen. Air that contains 10% of oxygen is extremely dangerous, for it will quickly suffocate anyone breathing it.

ELECTRIC POWER is usually contracted for by the kilowatt-hour or horse-power month, the latter being based on peak load. The terms of the contract naturally vary greatly. In western Nevada the price paid now averages probably $6.50 per month. Along the Mother Lode in California it is much less, perhaps an average of $4.50. In determining the rate to be charged, the power company must take into account the continuity of service and the probable life of the contract, in order to make an equitable distribution of fixed charges. A retail store that only wants extra lights Christmas week must naturally pay a high rate, since the fixed charge for the year for the investment necessary, must all be charged to the current used in the one week. On the other hand, a stamp-mill running steadily 24 hours per day and all the year around may expect to secure a low rate. In any event, the fixed charge for interest and depreciation is a high element of the cost. In a specific case a company selling 6000 hp. has an investment of approximately $400,000.

NEW YORK

Market Depression—Copper News—Lake Merger

It has been the pessimist's hour in Wall Street, the pessimist's week, in fact. A wave of liquidation has engulfed the market, and so far there has been no check, and no support offered to stay the course of the decline. Perhaps the most gloomy incident of the week was the return of J. P. Morgan, who came home playing solitaire and who evidently continues to be engrossed in the game. When Wall Street's duly appointed life saver has no comment beyond a grim, "Nothing to say," the strain becomes much more acute. It is quite evident that the business depression has become now a matter of national adjustment. The prevailing impression in Eastern financial centres now is that there is to be a period of dividend reductions, general retrenchment, and, probably, of stagnation of investment business, during which no new constructive enterprises can be launched. To be sure, this is a gloomy view, but the powers in Wall Street are beginning to realize that the movement against the too intense centralization of the country's principal industries has more behind it than political claptrap, the latter being a theory which the Street has developed and aired on all occasions. In the general slump prevailing, there has been no demoralization more complete than that which has overtaken the list of Canadian gold-mining shares. All of the classic utterances anent the Porcupine have been made to do yeoman service. His fretfulness, his loss of quills, etc., have been played upon in a running fire of comment on the disastrous setback to the market in the issues of the new Ontario gold district. Support seems to have been wholly withdrawn, and while news from the field of operations is fully as encouraging as could be asked or expected, market interest has been almost completely extinguished. Shrinkages are quite commensurate with the inflation which was insisted upon by the enthusiasts in the earliest days of the district, and if the blame lies anywhere, it is with those who would be satisfied with nothing short of doubly discounting the fullest possibilities of the future. The flotation of new enterprises, for a time a matter of daily occurrence, has ceased altogether, and as a natural, inevitable consequence, interest in mining circles generally is at a low ebb.

The acute condition of the coal strike in British Columbia has caused the British Columbia Copper Co. to suspend dividends, at least for the current quarter. There was a period when the company was somewhat discredited, just following the throwing up of the option held by the General Development Co. Now, however, the rehabilitation of the concern seems quite complete, and the board, which includes Colgate Hoyt, Edwin Hawley, Wm. B. Thompson, Anthony N. Brady, Newman Erb, is so strong as to stand out among mining companies in a most enviable light. British Columbia is producing about one million pounds of copper monthly and is keeping close to a cost of 9 cents per pound. Negotiations have been begun looking to the purchase of coal properties to forestall any possibility of future difficulty such as that in which the company now finds itself involved. The copper now being treated by the Tacoma smelter is looked upon as a threatening factor in the situation. The initial output from the Bonanza mine is given out as about 2,000,000 lb. per month. Curtailment at the other Guggenheim properties will hardly save the situation if an increasing supply of cheap copper is sent down from Alaska. The fact that the Guggenheims have put the Tacoma smelter into commission to handle these ores is looked upon as evidence of intended regular and probably increased shipments. The plain attempt to make much of the last copper statement failed to have the least stimulating effect, and from the present outlook it is quite safe to prophesy that the ground apparently gained during the past sixty days will be lost, or more than lost, during the next ninety.

R. C. Allen, State geologist of Michigan, has gone on record as favoring the merger of the Lake mines. Mr. Allen estimates the average copper content of the Michigan lodes at 1%, or 20 lb of copper per short ton, which at prevailing prices means $2.50 to cover all costs from the bottom of the mine to the consumer's stock pile. The deduction is that a large percentage of Lake copper is produced at an actual loss, and unless operating costs can be reduced the mines cannot continue to successfully compete with the low cost producers now turning out copper, or those developing whose cost sheets may possibly show some record figures in cheap production. There are some shareholders in the Lake properties who are much averse to saving other people's chestnuts from the fire. The Ahmeek stockholders seem to be strong on refusing to ratify the merger. John S. Jackson, an Ahmeek shareholder, has brought suit at Marquette, Michigan, asking a permanent injunction against the merger on the grounds of undervaluation of the Ahmeek. There seems to be an impression that this mine has a great independent future and a strong objection to its being used to 'sweeten' the big consolidation. The Jackson suit makes four actions now pending, seeking to prohibit the consummation of the proposed merger.

HOUGHTON, MICHIGAN

College of Mines Reunion Celebration.

The reunion at Houghton in celebration of the quarter-centennial of the Michigan College of Mines was such a decided success that at the suggestion of William Kelly, chairman of the Board of Control, it is proposed to hold a similar celebration every five years. Several hundred graduates, with their wives and families, the people of the copper country in a body, the students, faculty, and Board of Control of the college, participated in four days of carefully planned festivities. A desirable feature of the occasion was the enthusiasm with which the people of the copper country turned out for the occasion. The Copper Country M. C. M. Club appeared dressed in white canvas suits such as the Cornish mining men used to don for underground; the 'Iron Country' men displayed a broad hematite-red ribbon, with a railroad spike thrust through it; the M. C. M. Club of Chicago had elaborate badges of quartz and gold; quite a delegation was present from Porcupine and Cobalt; Mexico and Arizona were well represented; while telegrams poured in from South America, Japan, Australia, and other foreign countries, expressing best wishes for the success of the celebration. To William Kelley and F. W. McNair are due the idea and the execution of what was a huge undertaking. The speakers included Charles Nagel, secretary of the Department of Commerce and Labor; Charles Osborn, Governor of Michigan, whose son was a graduate of the college, class of 1910; and H. S. Drinker, president of Lehigh University; J. Parke Channing, who first suggested the founding of the college; and George Otis Smith, director of the U. S. Geological Survey. George W. Perkins, who was to speak on 'Wanted, a Constructive Business Policy', could not get away from the committee who is investigating the Steel Corporation, but his paper was read in his absence. Mr. Nagel made a profound impression. He discussed the large corporation in business, as a necessity to compete with European products. Of competition, Mr. Nagel said: "The people cry for competition in business, when in reality competition is to blame for most of the ills of the labor systems, namely, low wages, highest costs, and child labor." Further, "the American people are wont to feel a little sorry for themselves, and to complain of hard times when the times are good." He then cited instances of real hard times and mentioned the conditions in France just previous to the Revolution. Against the initiative, referendum and recall, Mr. Nagel spoke most eloquently. "Most of the people who support these measures," said he, "do so because they don't understand them." Although the different speakers did not know the topics upon which the others were to talk, nor indeed who the other speakers were to be, there was a noted coincidence in the opinions expressed concerning the necessity and desirability of the large corporation in modern business life.

BLACK HILLS, SOUTH DAKOTA

Golden Reward.—Mogul.—Wasp No. 2.—Dredging.

At the annual meeting of the Golden Reward Con. G. M. Co., held at Deadwood, the following directors were elected: A. G. Hackstaff, C. C. Tegethoff, O. H. Kahn, Harris Franklin, Robert W. Goelet, George G. DeWitt, Henry W. DeForest, W. B. Devereux, and Walter Luttgen. There were two changes, Mr. Hackstaff succeeding Charles A. Peabody and Mr. Luttgen succeeding August Belmont. Work of preparing plans and selecting equipment for the new roaster and cyanide plant is in the hands of Henry Schnitzel, general manager, and Frank Cazin, of Denver. Plans for the plants are practically completed, and it is expected that work will commence at an early date. The mines of the company, aside from the Astoria, where the new sulphide orebody was opened, are in good shape, and reports of officers submitted at the annual meeting showed a successful year just closed.

By the death on July 28 of William L. McLaughlin, the Black Hills lost one of its successful operators and best-known men. At the time of his death, which occurred at the age of fifty years, Mr. McLaughlin was general manager for the Mogul Mining Co., secretary of the Wasp No. 2, and a director and officer in a number of corporations of lesser importance. By profession and education he was a lawyer, and had made his home in Deadwood for thirty years. No appointment was made by the Mogul company to fill the position made vacant. Two of the officials from the Pittsburg office were in the Hills and considered the matter quite fully, but definite action was postponed until October 1. As at present operated, the property is in splendid hands, Edward Manion being mine superintendent, John V. N. Dorr, consulting metallurgist, and Charles E. Ellis, mill superintendent. The Wasp No. 2 officials are figuring on a steam-shovel, to be used in stripping the overburden on the north end of the property. At this point the stripping is considerably heavier than at other places. Total costs of mining and milling for June were 97 cents per ton, and during this month 15,000 tons were handled. Regular dividends of one cent per share per month and occasional dividends of an equal amount are being distributed. At the Bismarck, adjoining the Wasp No. 2, the work of tearing down the old mill and excavating for the foundations of the new plant is well under way, and simultaneously mining work is being carried forward. In the mine an adit is being driven to give direct connection with a raise where glory-hole mining will be undertaken. A gasoline-engine for haulage is being considered. W. W. Granger is in charge of construction; F. B. Hitchings is general manager.

OPEN PIT OF THE WASP NO. 2 MINE.

The Evans Consolidated company is figuring on the purchase of the Lexington Hill mill, a plant that is close to the workings, and which with the millsite would make a good addition to the acreage. The glory-hole workings are showing some good orebodies, carload samples of which have been shipped to the Lundberg, Dorr & Wilson mill at Terry. During July the Castle Creek dredge, at Mystic, handled 70,000 cu. yd. of gravel at a cost of 5 cents per yard. Results of clean-ups are not stated. Preparations are being made for winter work, the heating boiler being connected up with several hundred feet of coils.

N. Treweek, formerly State Mine Inspector, resigned his position with the Gilt Edge-Maid company to accept a place with the Homestake. Richard Tamblyn is now superintendent of the Gilt Edge-Maid. C. W. Merrill was in the Black Hills, and on his westward journey to San Francisco was accompanied by T. J. Grier, superintendent of the Homestake, who will remain away about one month.

CHITINA, ALASKA

Gold-Quartz Discoveries.—Copper Shipments.

This place is steadily becoming headquarters for prospectors, scattered up and down the Copper river and its various tributaries. Samples of gold quartz continue to be brought in, and now that the railroad is in operation, next spring will see one of the greatest quartz-mining movements ever known to Alaska. Near Mile 192 on Porphyry mountain, Bloomquist & Iverson have a fine lead of molybdenite that assays high in gold. They are now building a road from the railroad to the mine and expect soon to be making some high-grade shipments. John Barrett has returned to McCarthy creek from the Nizina with the news of a new find of free-milling gold quartz ore on Dan Creek mountain. The samples have been pronounced by geologists better than any of the surface ore taken from the Cliff mine. Mr. Barrett reported that Mr. Krum has started an adit that will give him considerable depth on his gold-bearing stibnite ore. He discovered this rich float two years ago and last year made his location. The Esterly hydraulic plant has been moved from Chititu creek to Rex gulch, and one or two clean-ups have already been made. The railroad company has made surveys for a spur from the main line into the McKinley Lake district near Agalanik, where the Alaska Syndicate and J. H. Lukach, among others, have bonded gold quartz properties.

Copper, however, continues to hold the attention of the public. Ed. Young, the contractor at the Nikolai mine, has just brought into McCarthy Creek camp some fine samples of bornite ore. Herman Keller, consulting mining engineer of New York, has completed his examination of the Mother Lode mine, which adjoins the Bonanza of the Kennicott Mines Co. The development has shown large deposits of chalcocite ore averaging over 60% copper. L. A. Lavensaler has active charge of this property. It is expected that high-grade ore will be shipped to the Tacoma smelter this fall, the shipments to be taken over the snow. The railroad survey for a spur to this property has been completed. The orebody is believed to be an extension of the Kennicott deposits. Mr. Keller is now at the Copper Mountain property of E. F. Gray, making an examination. Mr. Gray has developed a body of high-grade copper ore at Copper Mountain on the Kuskulana river, Mile 146 on the railroad. Mr. Gray's last adit is over 1000 ft. long and intersects the orebody 1100 ft. below the outcrop. He has also developed his Porphyry property, which promises to become a steam-shovel mine, rivaling the Nevada Consolidated property, with which Mr. Gray was connected during its development. He plans to erect this fall a 100-ton leaching plant for this ore, and the railroad has just completed a survey for a spur to the mine. This property is controlled by James Phillips, Jr., and associates of New York. Men formerly associated with the London Exploration Co. are developing a copper property four miles east of Mr. Gray's mine on the Kuskulana. The American Mining Co., a corporation formed for acquiring and developing properties, is also working on claims two miles from Gray's property. This company is composed of Alaska miners and railroad men, who have been in the country for years.

MEXICO

Sale of Tiro General. El Oro Strike. -English after Lucky Tiger.- Oil and Power.

The A. S. & R. Co. has just closed one of the most important deals of the year, taking over the Tiro General mines, in the Charcos district of San Luis Potosi, for ₱1,600,000. The purchase includes the Potosi Central railway, 10 kilometres long, extending from the mines to Los Charcos station, on the National Railways. The Tiro General Mining Co., composed principally of Aguascalientes and Mexico City men, has owned the mines for a number of years, and has shipped from 1000 to 4500 tons of ore per month to the Aguascalientes smelter of the A. S. & R. Co. The ore contains sulphides of silver and copper, with lead, zinc, and iron. A few years ago the company bought equipment for dry-concentration, but the treatment was not successful. The mines are *antiguas*, extensively developed, and are credited with a production of ₱20,000,000 in silver in the quarter of a century ending with 1895.

Strikes of workmen have continued in Mexico, and mining operations in several districts have been interrupted during the last few weeks. A strike of miners employed by some of the big foreign companies of the El Oro district, and the Dos Estrellas Co., a Mexican concern controlled in France, had tragic results, several strikers having been killed and a number wounded when the jail was stormed with the object of releasing the prisoners. The strike followed the organization of a *Liga Minera* (miners' league), one result of which was the distribution of anti-foreign circulars. Prices were placed on the heads of some of the foreign officials of El Oro companies. Leaders in the anti-foreign agitation were arrested, and as a direct result of this, strikes were declared. At one time several thousand men were out. The majority of the men returned to work within a few days. Operations in the Santa Eulalia district of Chihuahua were interrupted recently by a general strike of miners there. Strikes have been reported recently from the Inde and other districts of Durango.

English interests are endeavoring to make a deal for 90% of the stock of the Lucky Tiger Combination Gold Mining Co., owning the Lucky Tiger mine in Sonora, for $5,590,000. In connection with the deal, three London brokers recently made a trip to Kansas City, Mo., the headquarters of the company, and deposited $98,000 option money. They asked the privilege of buying, within six months, 370,000 shares at $7 per share, and within nine months 275,000 shares at $8 per share. The par value of the stock is $10 per share, but the present market price is but $6 per share. The stock outstanding totals 715,000 shares. The company looks for greatly increased earnings immediately, due to the completion of the 250-ton cyanide plant and the cutting of operating costs by the use of electric power, transmitted from the Copper Queen smelter at Douglas, Ariz. The Pacific S. & M. Co. expects to blow-in the lead smelter at Guaymas, Sonora, early in the fall. The plans of this company, which owns, through subsidiaries, the smelters at Guaymas and Fundición, have been delayed by disturbed conditions in Mexico. The production of the Moctezuma Copper Co., the Phelps-Dodge concern of Sonora, in the first seven months of this year, was 14,869,294 lb of copper, as against 13,576,450 lb in the corresponding period of 1910.

The Texas Oil Co. has purchased 80 acres of land at the Gulf port of Tampico, and will erect storage tanks there preparatory to purchasing Mexican crude oil for export to the United States. Due to the heavy production of the Huasteca Petroleum Co., a Doheny concern, the National Railways of Mexico are increasing the use of fuel oil for locomotives. Oil burners have been placed in service on the Mexican Southern and Interoceanic lines, and later the service will be extended to the Veracruz & Isthmus, Tehuantepec National, and Pan American roads. Huasteca oil is shipped to Ebano and there mixed with the Ebano product of the Mexican Petroleum Co. of California, another Doheny concern, which has the contract with the merger system. The annual report of the Mexican Light & Power Co., the Canadian concern that has the big hydro-electric installation at Necaxa, State of Puebla, and that supplies power to the Pachuca and El Oro mining districts as well as to Mexico City, shows gross earnings in 1910 of ₱5,021,625. The present generating capacity of Necaxa is given as 94,000 hp., and contracts recently let will result in increasing this capacity.

WABUSKA, NEVADA

Rapid Progress in Smelter Construction.—Farmers' Injunction Refused.—Tramway Construction.—Large Reserves.—Progress at Nevada-Douglas.

Rapid progress is being made on the smelter, now being built at Thompson, on the east side of the valley, about a mile and a half from Wabuska. This plant is being built by the Mason Valley Mines Co. to treat the ore from that mine and the Nevada-Douglas, and also to do a general custom smelting business. The plant is to have a capacity of 800 tons per day, and Jules Labarthe, the superintendent, who has general charge both of the smelter and the Mason Valley mine, expects that the smelter will furnish an outlet for the ores of the surrounding region, both to the north and south. The ores from the Nevada-Douglas and Mason Valley will give a smelting mixture that will contain 4 to 5% copper and only about 6% sulphur. It was to be expected that the action of Miller & Lux, who own large areas of grazing land near the smelter, little of which is of any value for agricultural purposes, in praying for an injunction to prevent the operation of the smelter, would be refused. In Shasta county, California, where damage from smelter fume has been alleged, the smelting mixture carries 30 to 36% sulphur, and in addition the climate is damp and the valley narrow. The climate at Thompson is dry, the valley is wide and open, and, in addition, observations extending over a period of two years have shown that the wind usually blows in such a direction as to carry the smelter gases only over barren land, very rarely blowing in the direction of the agricultural land in the Mason valley. Good progress is being made in the smelter construction. The stack is completed and most of the other brickwork is finished. The steel is arriving rapidly, and the construction of the blast-furnace building will be started soon. It is expected to blow-in the plant in November. A 45% matte will be made and shipped to the Garfield smelter. It is planned to use Utah coke for smelting.

At the Mason Valley mine, 1¼ miles west of the town of Mason, J. J. Welch, the superintendent, reports that the material for the 6600-ft. wire-rope tramway, furnished by A. Leschen & Sons Rope Co., is being delivered; actual construction should begin by September 1, and it is hoped to have the tramway ready within 60 days after that. The loading station will be at the mouth of the adit on the fourth level, and the discharge terminal will be at a siding on the railroad some 600 ft. below. The dump at the mouth of the third-level adit contains 30,000 tons of ore averaging 4½% copper, which can be drawn through raises from the fourth level, 140 ft. below, and loaded directly upon the tramway. The stopes in the mine are also in shape to produce at the rate of 300 to 500 tons per day when called upon to do so. Both the ore from the Nevada-Douglas and the Mason Valley, while nearly self-fluxing, has a slight excess of silica and needs the addition of lime. For convenience in handling, it was decided to use a limestone lying above the orebodies in the Mason Valley, rather than open a quarry in the hills east of the smelter. When this was done it was found that the limestone at that place carries 1½% copper, which will more than pay for the cost of handling it. The limestone will be milled down through chutes to the fourth level, where, together with all the ore from the levels above, it will be hauled by horses to the loading terminal of the tramway. The Nevada Copper Belt railroad is now in regular operation to Hudson, and the steel has been laid to the dump of the Ludwig mine of the Nevada-Douglas company. A surface tramway is being built from the Nevada-Douglas mine to the railroad. When the smelter is in operation these two mines expect to ship 200 tons or more daily of ore averaging 5½% copper.

JOHANNESBURG, TRANSVAAL

Grade of Ore in Depth.—Big-Mill Policy.

For 55 companies working on the Rand the average value of gold recovered per ton milled during the month of May was 27s. 6d. per ton, the Robinson mine being the highest, with 44s. 8d. per ton, while the Ferreira Deep comes next, with an average recovery value of 41s. 10d. per ton. This question of the average yield continues to crop up in different forms on the Rand, and just now has again come to the front somewhat prominently in connection with the general maintenance of grade in depth. Undoubtedly many mines on the Rand have yielded near the outcrop much better ore than lately, and in a few good instances the improved yield has been undoubtedly due to the reefs carrying more gold at and near the outcrop. Sufficient work has now, however, been done on the Rand to show that with depth there is not, as urged in some quarters, a general deterioration in value, as throughout the Rand there are numerous instances where down the dip there is a marked increase in grade as compared with the outcrop mines. If regard be had, however, only to the figures published by the local Chamber of Mines they would seem to indicate that a serious depreciation has actually taken place, but it is well known that recovery values per ton can be made to vary according to circumstances and conditions, and this is just what has happened on the Rand. In the early days when working costs were much higher than today only high-grade rock could be treated at a profit, but the adoption of the big-mill policy brought working costs down with a rush, and likewise the required grade to enable the mines to work at a satisfactory profit. Hugh Marriott and others have urged that this big-mill policy has been carried to excess and have pulled up several mines under their control with the request that more attention be paid to profit than to low-working costs. The Village Main Reef and Robinson Deep mines are two notable instances where this new policy has been adopted, and there is no doubt that the results obtained at these mines have had an influence on the policy at other mines.

Perhaps at one time too much attention in some cases was being paid to the question of low costs and too little to that of profits, but in the majority of cases on the Rand the big-mill policy, with its larger output and accompanying low working costs, has undoubtedly saved the situation. The Glencairn mine, for instance, has now a recovery value of only 15s. 1d. per ton, while the working costs amount to 13s. 4d. Still the profit for the month was £2517; a result entirely due to the big-mill policy. With a mill of 155 stamps, everything showing a trace of gold is treated, and any other policy pursued would soon end in disaster. Knights Deep is in a somewhat similar position, and by adopting a similar policy with a working cost of 11s. 6d. per ton, and a five pennyweight rock to treat a working profit of £24,325 per month is being earned, an achievement which many of the local mines cannot attain with seven and eight pennyweight rock to mill. Numerous other instances might be quoted where the big-mill policy is absolutely necessary for success, and in many of those cases where selective mining is and has been carried on with conspicuous success for a long time, it has in the end been necessary to adopt the big-mill policy so as to maintain the reputation of the mine.

While this question of yield is under discussion, it might be of some interest to compare those of today with Rand results of 21 years ago. In April 1890 there were only 950 stamps at work on the Rand and in the Heidelberg district, the total tonnage crushed being 49,860 tons, of which 3979 tons belonged to the Black Reef series. The duty per stamp per day was in the neighborhood of two tons. In those pre-cyanide days the whole of the yield was obtained from the plates, but it nevertheless averaged 13.89 dwt. per ton, the value per ton being £2 13s. 7d., as against £1 7s. 6d. per day. Since those days work on the Black Reef has ceased because the yield was too low to enable operations to be conducted at a profit, although it was 2s. per ton over the plates higher than the present-day total average yield. Even the Battery Reef in those days yielded over the plates alone the equivalent of today's yield from all sources, while the reefs belonging to the Main Reef series yielded no less than 14.24 dwt. over the plates at an average value per ton of £2 8s. 5d. It will therefore be seen that during the last 21 years, while the duty per stamp has been practically quadrupled; the yield per ton has declined by one half. Put into tabulated form for comparison the result would be as below:

Date.	Stamps at work.	Total tons.	Duty per month.	Yield per ton, dwt.	Value per ton.
April 1890	790	43,120	54	13.89	£2 13s. 7d.
April 1911	9,360	1,934,664	207	6.58	1 6s. 3d.

SALT LAKE CITY, UTAH

Competition for Lead Ores Makes Mining Active.

A great impetus is being given to lead mining in this region by more favorable smelter rates. While the International is rushing its lead smelter to completion, the American and United States companies are active in securing contracts. As a consequence, the mine manager with a desirable lead ore can now secure a far more favorable contract than has been possible for many a day. This is making possible the marketing of a large tonnage of low-grade ores which hitherto have been left in the mines or thrown over the dumps. For example, the May Day mine at Tintic has just closed a contract that will enable it to ship profitably ores running 5 to 7% lead, 7 to 8 oz. silver, and $3 to $5 gold, of which it has a large quantity. The company will also ship slime from the mill-dump. While the profits per ton on all this will be small, the shipments will be large. Other Tintic mines, in view of May Day's example, are beginning to figure on shipping largely from their dumps and from orebodies heretofore untouched because mining would not be profitable. Among them are Beck Tunnel, Colorado, Sioux, Iron Blossom, and Uncle Sam. Park City mines will also be benefited. The United States S. R. & M. Co. is active in its field work. It is reported to be considering purchasing the Grand Central at Tintic. The company is also making an examination of the Iron King mine, with a view to securing fluxing iron. The Dragon iron mine, adjoining, has been furnishing the company with this material for several years.

The Green River Gold Dredging Co., capitalized at $100,000, has been incorporated to work the placer claims along Green river from Clansman bar, near Jensen, to Horseshoe bend. Its principal place of business will be Vernal. C. Dudley Dean, of San Francisco, is president; Orren Allen, Denver, vice-president; J. R. Henderson, Denver, treasurer; Richard Leigh, Denver, secretary; and T. W. O'Donnell of Vernal additional director and counsel. The rest of the season will be devoted to preliminary work, as it is the intention to thoroughly prospect the claims before building a dredge.

ALASKA

Copper River

Messrs. Kearney, Berresford, Cokewell, Crosette, Gilmore, Laird, and Andrus, members of the Pearson syndicate party which investigated the Seward district, left Cordova early this month. One is quoted anonymously in the newspapers as stating that the country was promising and had prospective mines, but had not reached the stage necessary for development on a large scale. He stated that the syndicate sought developed and producing mines rather than prospects.

Juneau

The Treadwell company is making experiments in direct concentration of the ore without passing it over amalgamating plates. Twenty stamps have been arranged to deliver direct to vanners. The test will be continued one year. It is hoped that all free gold and concentrate by this method will be carried to the cyanide plant.

The monthly report of the Alaska United G. M. Co. states that the total production of the Ready Bullion claim in the month ended July 15 was $41,009, realizable value $40,342. The figures for the 700 claim are respectively $33,007 and $32,509. Operating expenses for the respective claims were $26,236 and $22,466, leaving the net operating profit as $14,105 and $10,042. The machinery bills for the new central hoist and crushers brought the construction expense for the R. B. claim to $2523 and for the 700 claim to $21,512. The yield per ton of ore milled was for the R. B. claim $2.36 and for the 700 claim $1.97

The Alaska Treadwell G. M. Co. has declared dividend No. 94, of 50c. per share, payable August 28.

Prince William Sound

D. M. Stewart has made the final payment taken on the option for mining property on Gulch creek, owned by W. H. Hammer. The option was taken last November, and, according to report, was for $25,000. After the option was taken the Dunfranwald G. M. Co. was formed and took over the property, which is free from debt and has mining machinery valued at $20,000. Much work has been done in constructing ditches and flumes, building the plant, and erecting cabins for the workmen. About 2000 cu. yd. of gravel is being handled per day. The deal is said to be the first in the district which has been effected according to the original contract terms.

Daniel Kain, manager for the Vancouver-Valdez M. Co., has made the final payment of $4000 to Charles Crawford and A. Y. Tuttle for their property adjoining the Cliff. An adit is being driven on the property. It is affirmed here that $20,000 already has been expended by the company.

Mrs. L. B. Kerwood of Minneapolis has arranged with the owners of the Beaver Dam claims, state press reports, to take over a 55% interest for $50,000. Mrs. Kerwood is said to represent a syndicate of Minneapolis capitalists. With D. H. Williams she also is arranging to take a half interest in the placer claims on Young creek owned by Joseph Murray, an attorney of Valdez, and Fred Stephenson and A. J. Diamond.

A large body of low-grade ore has been discovered on the Valdez-Bonanza property at the head of Mineral creek, according to report. A 5½-ft. vein of oxidized quartz is part of the find.

The Guthrie Belloli M. Co. has been incorporated to develop properties on Shoup bay. It is capitalized at $750,000, divided into $1 shares. The board of directors includes G. F. Guthrie, A. E. Belloli, L. Archibald, H. O. Henderson, and Edmund Smith.

Fearful of losing the stamp-mill for Valdez planned by C. R. Crawford, who believed he was not given proper support in his undertaking, the citizens of that city have set on foot a movement to secure funds for its establishment.

Excitement continues over claims located on the glacier, the latest discovery being made by Jack Curley and William Coleman. They have brought ore glistening with gold to Valdez, and assert that they found a 100-lb. specimen on the east side of the glacier which contained fully 2 lb. of gold.

The Tanana

Tom Aitken and a man named Cummings, representing the Guggenheim interests, according to press reports, are securing options on claims along Ruby creek, and will place drills on the property in a short while.

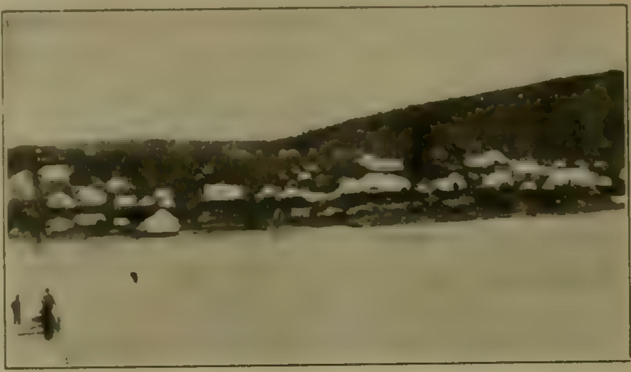
The English syndicate, which has the first dredge at Fairbanks, is transporting another for use on Fairbanks creeks. It is reported that still others will follow this dredge.

ARIZONA

Cochise County

It has been reported that work will be started soon on the foundations for the Paradise M. & M. Co.'s concentrator, and that the machinery will be received in the near future. The capacity is to be 100 tons per day.

Grover and Walter Reed, east Paradise, have completed the assessment work on the Homestake property. G. A. Walker had the contract for the work.



RUBY CITY, ALASKA, FROM THE YUKON.

Gila County

Miami Copper Co. will have produced 15,000,000 lb. of blister copper at the end of the year, according to report. The amount for the market in refined form by that date is estimated at 9,000,000 lb. By that time the placing in commission of all eight sections of its mill will give it a capacity of 30,000,000 lb. per year, possibly more. No agency contract for handling the copper has been made.

Maricopa County

(Special Correspondence.)—The Monarch M. & M. Co., which has been idle for the last three years, has contracted for a smelting plant, although the smelter site has not been selected. Custom ore may be treated as well as its own ore. A large amount of ore is reported on the surface where the vein has broken over. The vein is said to be 20 ft. wide and of good quality. C. W. Platt, of Wickenburg, is manager of the mine. A. D. Akin, of Macon, Ga., consulting engineer for the company, is making an inspection.

Wickenburg, August 21.

Pinal County

Ray Con. Copper Co., within two weeks, will be running four units of what eventually will be an eight-unit smelter, according to announcements coming from Boston. It is estimated that by 1912 the smelter will be producing 100,000,000 lb. of copper from its eight sections. The three now in operation, although planned for an output of 1000 lb. per day each, have exceeded that amount, and it is believed that soon each will be producing 1250 lb. of copper per day.

PIMA COUNTY

Press reports state that the Gundaker M. Co. has purchased the Mohawk property, which is adjacent to the Mammoth, about 45 miles from Tucson. The mine contains a low-grade gold ore, with some silver. S. W. Gundaker is president of the purchasing company, and John B. Wright is counsel and director for the company.

YAVAPAI COUNTY

(Special Correspondence.)—Grading has been started for the cyanide plant to be built by the Venezia G. M. Co. in Crook cañon. The machinery is on the way from the East. The plant will be the first of its kind in that district. E. L. Tomlinson is superintendent of the mine.

Prescott, August 19.

CALIFORNIA

AMADOR COUNTY

(Special Correspondence.)—The assay office of the Kennedy has been equipped with a rock crusher, sampler, and other apparatus. An ice-plant also has been established at the mine. The mill is treating approximately 500 tons per 24 hours, with a fair percentage of high-grade quartz coming from the rich vein on the 2800-ft. level. The Bunker Hill declared its regular monthly dividend on August 15, amounting to $10,000. Most of the ore continues to come from the massive vein on the 1950-ft. level. Repairs to the pipe-line and mill of the Zeila have been completed, and developments are again in full swing. Within a few weeks it is expected to have the mill running at full capacity. A new engine has been purchased, and there are rumors that a new shaft may be sunk by the company. The South Eureka company is unwatering the Oneida shaft. It is understood that underground connections will be made between the Oneida and South Eureka shafts as soon as the former is in working shape.

Jackson, August 19.

KERN COUNTY

The Associated Oil Co. of California has filed complaint in Washington against its former co-owner, the Southern Pacific Co., to recover $13,468 claimed to be overcharge for carrying oil from McKittrick and Olig through Bakersfield to Prescott and Selig, Arizona. At the time of the hauling the Southern Pacific owned 51% of the stock of the Associated.

It has been affirmed that the Government has succeeded in obtaining evidence through the Secret Service that $500,000 worth of oil lands has been secured fraudulently as non-mineral land and that indictments may be brought against men and organizations prominent in the oil market. James M. Sheridan, chief of the field division of the United States general land office, will have charge of the civil and criminal cases.

At a meeting of the executive committee of the Independent Producers' Agency next month a plan will be considered for issuing certificates on storage oil on a basis of 25c. per bbl., to bear interest at 6% per annum. The plan has been formed to enable producers to operate without curtailing production. A guaranty will be given that oil will not be sold for less than 25c. per bbl. Interest will be taken from monthly sales. After taking out interest, operating expenses, etc., providing a sinking fund for retiring bonds, it is stated the storage plant will be paid for in ten years. There would be storage for 20,000,000 bbl. of oil.

In the refining of oil the Union and Associated may compete with the Standard Oil Co., as they have undertaken refining as a side line. While crude-oil prices fluctuate, the price for the refined product remains at about the same figure.

English capitalists are reported negotiating with Con. Midway for 100 acres, sections 30 and 32, 12-23, Maricopa district, for $200,000. The income from the property is reported to be $10,000 per month. Engineers for the Guaranty Oil Co. state that it will cost $966,920 to construct the proposed pipe-line from Maricopa to Ventura.

NEVADA COUNTY

The 75-hp. hoist at the Golden Gate mine has just been placed in commission. It has a capacity of 6000 lb. and is one of the largest electric hoists in this district. The hoist was constructed by the Taylor Foundry & Engineering Co. of Grass Valley. W. P. Martin is superintendent of the mine. As soon as the mine is unwatered to the bottom, at the 600-ft. level, the shaft will be sunk farther, a station will be constructed at the 600-ft. level, and driving will be commenced.

SIERRA COUNTY

A new company has recently been organized under the name of the Black Sand Leasing Co., with a capitalization of $50,000, for the handling and treating of the black sand concentrate and tailing to be taken from the undercurrents of sluices at the E. L. Goldstein hydraulic mine near Brandy City. The Brandy City Mining Co. has been operating since the year 1857 and owns 800 acres of placer claims with a face of over 180 ft. It has given a three-year lease on the tailing to the Black Sand Leasing Co., and it is reported that the tailing assays high in gold and platinum. Tests have been made with the separator manufactured by the Automatic Gold Separator Ltd. of Los Angeles, and these are reported to have shown recoveries of all the platinum and all but a trace of the gold. The Separator company has taken an interest with the Black Sand Leasing Co. in the handling and treating of the tailing. A plant will be erected at once and will be in operation in September. The officers and directors of the Black Sand Leasing Co. are Lew Robertson, president and general manager; J. A. Bothwell, vice-president; C. H. Gowman, secretary-treasurer; with W. E. Bechtelheimer and L. W. Partridge on the list as directors. All are of Los Angeles except L. W. Partridge, who is of Detroit, Michigan.

TUOLUMNE COUNTY

(Special Correspondence.)—The cross-cut on the twenty-second level of the Black Oak mine has penetrated 3½ ft. into the vein, but has not passed through it. The ore from the entire face is reported to assay as high as $91 per ton. Driving continues on the fourteenth and fifteenth levels.

Soulsbyville, August 21.

(Special Correspondence.)—Work in the Kanaka shaft was stopped suddenly a few days ago as a result of a large increase in the flow of water, which cannot be handled by the pump. This will not interfere with the driving of the adit, where good progress is being made. A larger compressor and a new pump will probably be purchased at once.

There is great activity at the Rio Tagus, formerly known as the Contention mine, about 30 men being employed in erecting buildings and putting in a complete equipment. The company, whose general manager is L. B. Dodd, recently completed a sawmill and is now at work on a 10-stamp mill and a large compressor. The plant will be operated by water-power, but it is the intention to put in electric motors and connect with the power-plant situated nearby. The property has been developed by a shaft and an adit several hundred feet long. Much of the ore assays $18 per ton.

The Fair Oaks mine, on Mount Provo, near Confidence, has been bonded to the Alta Investment Co. of Los Angeles, for $15,000. The property has a 5-stamp mill and has been opened by a long adit and a shaft 100 ft. deep. The ore, from a 2-ft. vein, mills from $6 to $12 per ton.

J. C. Gordon and J. L. Brooks are working on a 30-in. vein near the Densmore mine which assays from $50 to $200 per ton. A shaft has been sunk 80 ft. and 36 tons of ore taken out in development has just been milled.

At the Empire, operated by L. H. Jansen, work has been resumed in the winze on the 200-ft. level. Preparations are under way for resuming work at the Duffield, near Arastraville. The owners of that property will soon commence development of the Little Sonora mine, in the same district.

It is understood that the Central Mother Lode Mining Co., at its recent meeting held in Sacramento, decided to resume operation at the Mangante mine, near Jamestown, in the near future. It is said that the shaft will be sunk an additional 100 feet.

The North Star mine, one mile north of Tuolumne, owned by J. M. Aston, of Oregon, and associates, is being retimbered preparatory to the resumption of operation.

The Philbert G. M. Co. has filed articles of incorporation in this county. The capital stock is $100,000, shares $100 each. The directors are George H. Walker, Maggie Walker, O. J. Johnson, Philip Nicoll, and Flor G. Galusha, all of Los Angeles.

Tuolumne, August 11.

COLORADO

Clear Creek County

(Special Correspondence.)—A body of solid smelting ore from 8 to 9 ft. wide is showing between the eighth and ninth levels on the Shaffer mine. The product mills $35 per ton in gold. Shaffer Bros. are operating under lease. A streak of ore 14 in. wide has been uncovered on the adit-level of the Ben Harrison mine. Tests show ore assaying as high as 700 oz. silver. J. D. Armstrong and W. H. Williams are owners. Charles Fuller and others have taken a lease on the fifteenth level of the Gem mine, 1000 ft. of ground being controlled. A plant of machinery has been purchased for the Metropolitan adit. Thomas Coppard is manager.

Idaho Springs, August 10.

Dolores County

Press reports state that the United Rico M. Co. will resume operations on a large scale. H. Gedet, president and general manager for the company, is in New York to attend a reorganization meeting.

Hinsdale County

Great interest is being shown in experiments with the Rankin process, now being used in a new mill at Lake City. It is claimed that this method, in which nitric acid is the principal chemical, will greatly reduce the cost of extraction.

La Plata County

Ore assaying $460 per ton, according to report, has been found two miles from Durango by O. N. Kee, a prospector sent out by the grubstake committee of the Denver Chamber of Commerce.

Ouray County

It is believed that the Red Mt. R. R., M. & S. Co. will resume operations in its groups of the Crawford properties. Judgments amounting to $12,000 have been paid by A. Thompson, the receiver for the company.

The Atlas M. & M. Co., Sneffels district, has put in an additional 10-stamp battery.

San Juan County

Ore producers here have been assured of the construction in the near future of a custom cyanide plant near Silverton. John T. Milliken, of the Golden Cycle company, has been investigating the field for such a plant. A test made by Silverton assayers of $11 ore from Ice Lake basin showed a recovery of 92% of the gold and 66% of the silver. Tests of ore from the Eastern range gave encouraging results.

Teller County

The C. K. & N. mine at Cripple Creek after lying idle for about three years, has been reopened with a force of 20 men, according to press reports. This step was possible through the drainage afforded by the Roosevelt deep drainage tunnel, which lowered the water-level to the bottom of the shaft, 835 ft. deep.

IDAHO

Kootenai County

Construction of a main working adit 6000 ft. in length, on the Hercules property in the Coeur d'Alene, was reported assured when stockholders of the Humming Bird M. Co. confirmed the action of the directors in leasing their No. 5 adit to the Hercules people. It was decided to renew development on the upper workings of the Humming Bird property, where the showings are encouraging. Driving on the No. 5 adit was suspended two years ago, after 2000 ft. had been completed. The new directors of the Humming Bird company are: president, Harry L. Day; vice-president, Eugene R. Day; secretary and treasurer, F. M. Rothrock; L. W. Hutton and August Paulsen.

Announcement is made that work will be resumed on the Snowstorm Apex property in the Coeur d'Alene district in September. One hundred feet of tunnel will be driven. At the annual meeting a few days ago the board of directors was re-elected, with A. B. Babb president and general manager.

Lemhi County

Directors of the Pittsburg Idaho mines at Gilmore have just declared a second dividend of 3c. per share. The new compressor which was ordered some time ago and the pneumatic drill are now being placed.

Shoshone County

At the Stewart mine, near Wardner, work has been started on a 2000 ft. adit to tap the orebody at a lower level. It commences opposite the Caledonia's adit mouth and will be on the same level.

MICHIGAN

Houghton County

The report of the Wolverine Copper M. Co. for the year ended June 30 shows the total receipts were $1,209,747. Other figures from the report are: total expenses, $723,123; mining profits, $487,896; construction, $2191; net profit, $485,705; dividends, $600,000; total surplus, $673,340. The figure for receipts has been slowly descending since 1909, when it was $1,342,382. The average price received for 9,167,618 lb. of copper was 12.58c. and the cost of production was 7.542c. The average recovery was 24.75 lb. of copper per ton. The mineral production was 12,227,500 lb., of which 78.65% was copper.

The Old Colony M. Co., since starting diamond-drill operations three weeks ago, has taken out a rich core from hole No. 8 which shows nearly a foot of ore well filled with shot-copper. The ore in character is almost identical with that found by the Mayflower, north, and by the St. Louis, south of the Old Colony property. Old Colony's first drill was sunk 650 ft. northwest of the southeast corner of the property, to meet the eastern sandstone. This was found more quickly than expected and is believed to have a roll toward the west in that direction. Hole No. 8 was the second undertaken and is 650 ft. northwest of the first hole. The present drilling is about 2000 ft. northeast of where the St. Louis is sinking a three-compartment shaft.

Iron County

(Special Correspondence.)—The Lake Superior Mining Institute held its sixteenth annual meeting on the Menominee range, August 22, 23, and 24, with W. J. Richards, of Crystal Falls, general superintendent for the Corrigan-McKinney interests, as president. Attention was paid to developments in the Crystal Falls and Iron River districts where diamond-drilling is greatly enlarging the known area of iron-ore formation; to the matter of electric power for the operation of mines which is attracting notice on the Marquette and Menominee ranges; to the recent advance in safety appliances and prevention of accidents that the Oliver Iron Mining Co. and the Cleveland-Cliffs Iron Co. have instigated; and to certain underground mining methods of which the Menominee range practice offers excellent examples. The last meeting on the Menominee range was in 1905, since which date meetings have been held in the copper country in 1906, on the Mesaba and Vermillion ranges in Minnesota in 1908, at Ishpeming in 1909, and at Ironwood and Chicago in 1910. The Institute has about 600 members, including nearly all men prominent in the iron and copper mining industry of the Lake Superior district.

Iron River, August 24.

MONTANA

Lincoln County

(Special Correspondence.)—Joseph A. Coram, owner of the water-power site at the Kootenai falls, twelve miles west of Libby, is planning to form a company to develop the water-power there. The water in the Kootenai river, which is the largest in Montana, according to government reports, goes through the Purcell mountain gorge in Lincoln county in a succession of falls and rapids. The horse-power capable of being controlled is estimated at 200,000 at low-water mark, and as high as 357,000 during high water. There are no great engineering difficulties to overcome in connection with the work.

Libby, August 20.

(Special Correspondence.)—Peter Sorrenson has returned to Libby from his mining claim on Great Northern mountain, bringing out with him some samples of ore which, when pounded up and panned, yield considerable free gold. The vein on his claim is about 3 ft. wide, the stringer carrying the most gold being about 3 in. wide.

Libby, August 13.

SILVERBOW COUNTY

(Special Correspondence.)—The Never Sweat mine has resumed operations. It is rumored that in the course of time the Never Sweat shaft will be abandoned and that the ore will be hoisted through the Anaconda shaft.

The strike of section hands on the Butte, Anaconda & Pacific railroad did not interfere with the operation of ore trains. The men have returned to work.

Good progress is being made in surface improvements at the East Butte, and it is thought that the work will be completed by the first of December. The improvements include the erection of a large dust-chamber, a plant for sintering flue-dust, and a dam for impounding tailing. Ore assaying from 7 to 10% copper is being blocked out. Development work is being pushed on the 800, 1000, and 1200-ft. levels.

In two months the cross-cut from the Black Rock of the Butte & Superior mine to the Pilot Butte ground, at a depth of 1300 ft., should be completed. It is half done at the present time.

Butte, August 21.

NEVADA

ESMERALDA COUNTY

(Special Correspondence.)—The Mexican mine made a new record for itself in last week's production, which was the largest in its history, $34,417, or nearly $6000 per working day. The last record, made two months ago, was $26,000. The Mexican's production brings the record weekly yield of the north-end properties, the Mexican, Ophir, and Union Con., to $42,972, and with $2163 from Crown Point makes the total yield, as recorded in the reports of superintendents, $45,135. The Mexican's output is 76% of the whole Comstock Lode. Whitman Symmes, superintendent of the Mexican, reports that grading is being done for the mill foundation. Jointly with the Sierra Nevada and Union Con., construction work on the new store-house has been done, together with repairs on the main hoisting shaft.

Virginia City, August 22.

NYE COUNTY

(Special Correspondence.)—In a general report to the stockholders of the Dexter subsidiary companies, submitted by Percival Nash, secretary, there is a recommendation that the Manhattan Union Ext. M. Co. absorb the Dexter Crown, Dexter Prince, Dexter Queen, Dexter King, and Manhattan Dexter Extension mining companies. The Union is in the producing class and has the same stockholders, and holds the same amount of stock in each of the five companies proposed for the deal. Excepting for 300,000 shares placed in the treasury of each of the eight Dexter companies, the stocks were pro-rated to the Manhattan Dexter M. Co. stockholders, the stocks being placed in pool in the Tonopah Banking Corporation. It was intended to secure funds for development work by selling treasury stock before dissolving the pool. The continued depression in southern Nevada, and particularly Manhattan stocks, checked the plan. Lessees on the Dexter White Caps No. 1 claim have proved an orebody of considerable size and the two shafts and workings, 300 ft. apart, are reported on the same body. As there has been considerable trading in assignments in the White Caps company, objection has been raised to having it absorb the other companies. At present the producing companies are carrying the burdens of the non-productive ones, and stockholders have been asked to signify their approval or disapproval of the Union Extension company's absorbing the other Dexter subsidiaries excepting the Dexter White Caps and the Dexter Merger. A. G. Raycroft, of San Francisco, is president of the subsidiary companies; R. C. Moore, of Los Angeles, treasurer; and the Tonopah Banking Corporation is the depository. Hugh H. Brown, Tonopah, vice-president of the company, is counsel.

While the inactivity in stocks has affected the Litigation Hill Merger M. Co., some revenue has been received through lessees, who incidentally have prospected parts of the various claims without cost to the company. The leases are considered a temporary expedient, and the longest one is for a term of 18 months. A well defined dike of limestone traverses the full length of Litigation hill, its average width being over 200 ft. The dike is a coarsely crystalline pure carbonate, soluble in surface waters, and has in the deposition of the orebodies been replaced by silica and changed into quartz. The Litigation Hill Merger Co. is a compromise settlement between the Manhattan Union M. Co. and the Liberty & Justice G. M. Co. The title is a U. S. patent with two small exceptions.

Manhattan, August 20.

WHITE PINE COUNTY

(Telegraphic Correspondence.)—Six miners are dead and four are at the point of death through fire breaking out in the 5-compartment shaft of the Giroux Con. mine Wednesday night. While on the 1400-ft. level they saw the flames above in the shaft and signaled to be drawn up. Of five that stayed in the cage one was dead and four were near death on reaching the top. Five others who attempted to reach the old Alpha shaft from the 1200-ft. level perished. T. J. Gilmore, shift boss, is one of the head.

Ely, August 24.

(Special Correspondence.)—By a series of changes the capacity of the reverberatories at McGill have been doubled during the past few months. Formerly the capacity of the reverberatories was about 250 tons of calcine daily, but this was steadily raised until 500 is now the general average of No. 1, and during one day of the present week 622 tons of calcine was put through, which stands as the world's record. The best record of the furnaces at Anaconda for 24 hours was less than 500 tons. No. 1 at McGill is 121 ft. in length, and is said to be the largest in the world at the present time. All reverberatories there are now burning oil for fuel, which greatly increases their capacity, and lessens the cost of smelting.

The new Liberty pit of the Nevada Con. is nearing production. Two steam-shovels are used in stripping away the overburden. An ore railway is being built into the pit on a lower line than those that remove the overburden, and will be in operation within a few weeks, when the new pit will be called upon for an average of 2500 tons of ore daily. For months past the Copper pit has been supplying 10,000 tons of ore daily, and apparently could stand the drain indefinitely.

In the Zack mine of the Ely Con., a drift is being run on the 500-ft. level to connect with the old workings of the American mine, a distance of 3000 feet.

Ely, August 19.

NEW MEXICO

GRANT COUNTY

It is announced that the Chino Copper Co. will commence shipments of copper concentrate to the El Paso smelter in the middle of September, when the first of the three 1000-ton unites of the new mill will be in commission. The Chino concentrating plant will consist of crushers, rolls, jigs, tables, and vanners, and will be operated by electric power generated by steam-engines. It is stated that within two years its capacity will be increased to 3000 tons per day. Hurley, where the mill is under construction, is on the Deming-Whitewater branch of the A. T. & S. F. railroad, and the Santa Rita mines, whence the supply ore for the mill, are 10 miles north-east of Hurley. Five steam shovels are at work at the mines, and a large supply of ore will be ready for the mill. The camp has long been noted for its supply of copper and mines have been worked here for over a century.

WASHINGTON

Spokane County

L. K. Armstrong, superintendent of the mining department of the Spokane Interstate Fair, is making preparations for a convention of mining men from all parts of Washington, Oregon, Idaho, Montana, and the province of British Columbia at the fair in Spokane the week of October 2. The Spokane Mining Men's Club and the Spokane Chamber of Commerce will co-operate with Mr. Armstrong in making the meeting the most important of its kind in this part of the country.

ROMERO OPEN-CUT AND OLD MINE WORKINGS, CHINO COPPER MINE.

WYOMING

Crook County

(Special Correspondence.)—Pegmatite forming the Bear Lodge laccolith, eight miles west of Sundance, is reported by Edwin Hall, late State Geologist of Wyoming, to assay $5 per ton in gold, outside the small veins containing fluorite that traverse the mass. A company called the Bear Lodge Gold Mining Co. has been formed to work the property. The manager is P. W. Shafer and the offices are at Sundance.

Sundance, August 19.

CANADA

British Columbia

(Special Correspondence.)—The Granby company will close its smelter on the exhaustion of its supply of Connellsville coke, on account of the coal miners' strike, which has affected western Canada for the last three months. Coal strikes have taken place at frequent intervals in British Columbia for the past few years, and the purchase by the Granby company of the minority interest in the Crow's Nest Pass Coal Co. was to circumvent such troubles. The latest strike, however, included the miners employed by that company. The cost of transportation prevented the use of Pennsylvania coke, although the British Columbia Copper Co., at an added cost of $25,000 per month, used the Pennsylvania fuel in the same district.

[illegible], August 1.

Yukon

Exceptionally rich placer deposits have been found on McClintock creek, entering Marsh lake about ten miles from Tagish post, Yukon Territory, according to telegraphic despatches from Skagway. Carcross is being deserted, and from other towns great numbers are leaving for the field. The ground is not frozen, and the gold, which is coarse, appears to be plentiful.

Ontario

(Special Correspondence.)—The North Dome M. Co. has found a spectacular showing of free gold in the new vein, according to C. W. Nelson, superintendent for the company. The vein is 6 ft. wide and the free gold is scattered through 5 ft. of it. An assay from 22 in. across the free-gold pay-streak showed $2900 per ton. The discovery is said to be the best made in the camp. A new drill-hole is being sunk 280 ft. northeast of No. 1 shaft. Two shifts are being worked in the cross-cut adit toward the Dome Extension vein.

Porcupine, August 20.

MEXICO

Jalisco

The El Tajo M. Co. will increase largely the tonnage of the ores handled in its reduction-plant, as the machinery recently added is now in operation. It is reported that soon at least 100 tons per day will be treated. The plant consists of 20 stamps, two tube-mills, concentrators, and a complete cyanide equipment. Edwin Shapely, assistant general manager of the mines, recently shipped bullion worth $10,000, the result of the last clean-up, to the refinery in Mexico City.

San Luis Potosi

The American S. & R. Co. has purchased the Tiro General mines and the Central Potosi railroad, 10 km. long, which connects the mines at Charcos with the Los Charcos station of the National Railways of Mexico. The price is reported as ₱1,600,000.

Personal

Professional men are invited to send news of their engagements and travels. Such news is interesting to friends.

[illegible] has been in town.

[illegible] is at Ely, Nevada.

[illegible] has gone to [illegible].

[illegible] has gone to New York.

[illegible] is at [illegible], Utah.

[illegible] has gone to Ely, Nevada.

[illegible] is visiting the State of Washington.

[illegible] is in [illegible], Chihuahua, Mexico.

[illegible] is at [illegible] Valley, making a mine examination.

[illegible] Roberts, director of the Mint, is in San Francisco.

W. S. [illegible] has been at Salt Lake City, and has gone West.

[illegible] S. King has returned to San Francisco from [illegible].

W. [illegible] has returned to Mason, Nevada, from a trip to San Francisco.

[illegible] has returned to Montana and is now in Kingman, Arizona.

[illegible] has gone to Salt Lake City from Tonopah, Nevada.

[illegible] is on examination work in Mexico for New York interests.

S. F. Shaw has resigned as manager of the Montezuma mines of Costa Rica.

J. W. Hutchinson has gone to Denver, where a son was born to him last week.

W. H. [illegible] is making mine examination on the Mother Lode in Mariposa county.

[illegible] was in San Francisco, returning from [illegible] to New York.

R. P. [illegible] has left Battle Creek, Michigan, and is in Los Angeles on a business trip.

Francis A. Thomson has returned from examination work in the Ten-Mile district of [illegible].

[illegible] and [illegible] have been at Ely, Nevada, and have gone to Salt Lake City.

[illegible] has gone to Copper Center, Alaska, to examine placers. He will be gone six weeks.

F. C. [illegible] is manager for the A. S. & R. Co., which is to reopen the Silver Lake mine at Silverton.

[illegible] E. Brown has left Medellin, Colombia, for London, and will be in Dumbartonshire, Scotland.

C. H. [illegible] left London for Buenos Aires on August 4, to resume charge of the [illegible] mine in Chile.

[illegible] is in Plumas county on a professional trip. He expects to return to Sacramento in about two weeks.

[illegible] H. Kay has resigned from the service of the Southern Pacific to become a member of the State Geological Survey of Illinois.

[illegible], a young mining engineer, disappeared from his camp on Feather river in Plumas county, and it is feared that he has been killed.

J. W. [illegible], for several years mine superintendent for the Consolidated Mines Co. at Goldfield, has resigned owing to the ill health of his wife and will move to Los Angeles.

J. F. [illegible], general superintendent for the Consolidated Mines Co., has returned from a vacation on the Coast, and [illegible], who was acting as manager in Mr. [illegible]'s absence, has returned to San Francisco.

[illegible] J. [illegible], who died at Salt Lake, August [illegible], [illegible], was an Englishman by birth, though he spent his boyhood in [illegible] and his working years in the Western States. He was well known for excellent work in Colorado, Montana, and Utah especially. His attention was devoted mainly to ore dressing, and among the large mills built by him were the [illegible] and that of the Boston Con. at Bingham, Utah.

JAPANESE shipments of copper to the United States are expected to amount to 20,000,000 pounds this year, an increase of 3,000,000 pounds over those for 1910. The metal comes mainly in the form of blister copper and is refined on the Atlantic coast.

TANGANYIKA Concessions is now producing about 28,000 pounds of copper per day. During July 830,000 pounds of blister copper was shipped from the Kansanshi mine. At this rate the yearly production would amount to about 8,000,000 pounds. This is the first return on the large investment made by Mr. Robert Williams and his associates.

MEXICAN bandits continue to make trouble at outlying mines. Last week they raided the Pedrazzini mine at Chispas, Sonora, and carried away money and stores. The *rurales* are after the bandits, but in the meantime Mr. Edward L. Dufourcq has before him the difficult problem of operating without sufficient supplies; a problem apt to confront other managers before matters become altogether normal again.

SUMMER as well as winter trails in Alaska have their perils. In July this year Mr. R. S. Tarr and Mr. Lawrence Martin, experienced Alaskan travelers, lost their equipment and narrowly escaped losing their lives while crossing the Delta river on the Chitina-Fairbanks trail. That highway into the interior is being rapidly improved for all year service, but at present a summer trip over it involves much more risk than the journey when the rivers and the ground are frozen.

ZINC has been mined in increasing quantities in northeastern Oklahoma since old Indian Territory days. The mineral has also been frequently reported in the southeastern part of the State. Apparently deposits have now been found in the Arbuckle mountains that show real promise, though Mr. L. C. Snider of the Oklahoma Geological Survey finds it necessary to suggest a bit of caution regarding some of the claims. It is but natural that in a region where metal mining has been unimportant even a good find be over-rated. Such things occur, to the sorrow of many, in well established districts. The promptness with which the officers of the Survey have investigated the new district testifies to their interest and activity.

AMONG the new porphyry copper mines now coming into production the Ray Consolidated promises the largest immediate output. Within a couple of weeks it is expected that 5000 tons per day will be mined, this corresponding to one-half the ultimate capacity. We present this week a full description of the property written by Mr. Charles A. Dinsmore, and at the same time our New York correspondent notes the sale of the partly complete smelter at Hayden to the Guggenheim interests, and moralizes a little over the probable outcome. Ray Consolidated has been much in the public eye in the last two years. Evidently foundations have been well laid and Ray is to continue a centre of interest to both technical men and financiers.

PHOTO-LITHOGRAPHED copies of original plats are permitted to be used in place of the duplicate, triplicate, and quadruplicate drawings heretofore required in patent proceedings. These copies will be prepared in the General Land Office from the original, traced and white drawing prepared as hitherto. Extra copies will be furnished at cost, including one on tracing paper from which blue prints may be made. The effect of this change will be to reduce the cost of patent proceedings, perhaps as much as $10. The only criticism of the new order that has been made is to the effect that its late announcement may have caused those not going to patent enough to require an additional year's assessment work.

APPRAISAL of the mines of a whole State has seldom been attempted, but such an inventory for Michigan has just been completed by Mr. J. R. Finlay, acting for the State Tax Commission. We print this week a brief abstract of his report and will present the details later. It is clear that in fixing the value of mines for taxation purposes only present value is properly taken into account, and valuations of present value of mines are so rarely made in the United States that Mr. Finlay's report has been eagerly considered. A mine may have excellent possibilities for the future, but these are hardly to be taken into account in taxation. Comparisons of taxation values and stock-market appraisals are apt to show wide differences. That the method used by Mr. Finlay, one well known to all practising engineers, rests on well grounded principles is indicated by the general agreement between his figures and those reached by Mr. J. Parke Channing when valuing some of the same properties for consolidation. Mr. Finlay values the Calumet & Hecla at $51,000,000, Mr. Channing at $[illegible]. Both agree that the Tamarack has no present value, and Mr. Channing is more generous to the Ahmeek, whose stockholders have been fighting the proposed consolidation, than is Mr. Finlay; the one placing a value of $[illegible] on the property, and the other $7,200,000. There are minor differences, but a general agreement throughout. One matter that will interest many is that Mr. Finlay bases his valuations on a 14-cent price of copper. His reasons for this are interesting, but too long to quote in this place. The whole report is worthy of detailed study by engineers.

The Cottrell Process

Smelter-fume problems have received much attention in the Western States in the last few years. Not all the money has been spent in litigation, and substantial advances in efficiency have resulted. Probably none have been more interesting than those centering around the electrical precipitation of suspended particles. Mr. F. G. Cottrell, to whom is chiefly due the success of this invention, described his methods and apparatus last June at the meeting of the American Chemical Society, as we noted at the time. His full account of the matter has since recently been published in the Journal of that society. We print this week the concluding part of an extensive abstract of his paper. Prior to this publication by Mr. Cottrell no authentic account of his work has been so issued, and only a meagre description of the apparatus, together with general accounts of results, was available. Mr. Cottrell has until recently occupied a position in the department of chemistry of the University of California. This he has resigned to devote his whole time to research under the direction of the United States Bureau of Mines, and further solution of smelter-fume problems are to be his first work. At present, while final results are still in the future, there is a satisfactory record of accomplished results. The process is in daily use at one of the acid plants on San Francisco bay. Another type of apparatus is in successful operation in the oilfield separating water and oil. A third plant, erected at the Selby Smelting & Lead Company, proved entirely successful. At the Coram works of the Balaklala Consolidated Copper Company, a measurable success was achieved, despite the necessity for hurried erection of a plant many times larger than the experimental unit. At times 80 per cent of the suspended matter was precipitated, and there is little reason to doubt that the whole plant could have been ultimately brought up to that degree of efficiency. The smelter, however, is closed, and into the closing entered a variety of matters aside from the efficiency of the precipitating plant. Experimental work is to be continued at Garfield, Utah, with the object of making a better saving of flue-dust. Following months of work with a small unit, the complete plant of the Riverside Portland Cement Company is being equipped with the Cottrell apparatus. On the whole this is a cheerful record of progress; with some disappointments, it is true, but none the less with some things substantially accomplished.

The Lesson of the Giroux Fire

The trite saying that it is always the unexpected which happens, was never better illustrated than by the news despatches of last week, bringing the information that a fire had occurred in the Giroux shaft of the Giroux Consolidated Mines Company, and that a number of men had lost their lives. Nothing more unexpected could have occurred. The Giroux shaft is now 1400 feet deep; it was raised from workings connected with the 1000-foot level of the older Alpha shaft some 750 feet farther north. The 1200-foot level is also connected with the Alpha shaft. The Giroux is now being sunk below the 1400-foot level. At the 1200-foot level is the concrete pump station. The five-compartment shaft is timbered throughout and just below the collar it is encircled by a three-inch pipe, bored with quarter-inch holes every six inches, and connected with a 20,000-gallon tank so that 600 gallons of water per minute may be discharged into the shaft. This may be continued indefinitely, as the tank is connected with the pump discharge. It will be seen that unusual precautions had been taken to guard against fire in the shaft.

On Thursday of last week the men at work in the shaft heard a noise, and looking up, discovered that the shaft was on fire above the 1200-foot level. Ascending in the cage to that level, they disagreed as to procedure, and five decided to walk through to the Alpha shaft, intending to climb out the ladder way. Five others decided to try to pass through the fire in the cage. They reached the surface all badly burned, one being already dead, and one dying later in the hospital. None of those who went to the Alpha shaft escaped. With the data at hand it is impossible to fully explain the accident, but probably the water was turned on in the main shaft before the men were out, changing the Alpha from a down-cast to an up-cast shaft, driving the smoke into the Alpha workings and killing the men who were seeking safety. What is the lesson? Here apparently every reasonable precaution had been taken, yet a disastrous accident occurred. Much might be said—that the presence of safeguards induces a too great feeling of safety, that systems for fire protection will not always work, and many other platitudes. The essential point after all is that men lose their heads in emergencies and nothing can prevent an otherwise careful man from doing, under stress, exactly what he should not do. Training in rescue work will do much to inculcate in miners what may be designated as an emergency habit of mind and prevent the occurrence of accidents such as this. Not only must appliances be furnished, but plans laid and men trained.

Are Veins Richer in Depth?

Whether gold bearing veins become consistently richer or poorer in depth is a question still much debated. There can be little doubt that mines generally yield their richest ore at or near the surface. On the average there is undoubtedly more ore in the first thousand feet from the surface downward than in the second, and down to depths so far mined, probably each succeeding thousand contains less than the one above. It is also true that in nearly every district the average grade of the ore now mined is less than the average of earlier years, and, as each mine gets older, poorer and poorer ore is sent to the mill. All this may be said without altogether settling the main question. These easy appeals to experience somehow fail to carry complete conviction and rules deduced from them receive rude shocks from time to time.

In the annual report of the Alaska United Gold Mining Company, reviewed on another page, it is shown that in the Ready Bullion mine the average value of the ore reserves as reported from year to year since 1901 has been \$2.527 per ton and the average value of the ore actually milled has been \$2.061, while the average value of the present ore reserve is \$3.02. For the 700-Foot mine of the same company the corresponding figures are \$2.328, \$2.335, and \$2.51, while for the Alaska Mexican they are \$3.26, \$3.10, and \$3.41. Taking the whole group of mines on Treadwell Island, the average of the ore milled has been about \$2.40 per ton, while the average value of the ore now in reserve is probably over \$3. These figures are the more significant since gold alone enters into account and there is no question of fluctuating prices of other metals. At present work in these mines is deep; roughly, 1200 to 1500 feet. The ore is coming mainly from the second thousand feet of depth, and yet it now averages better in grade than that mined during the whole history of mining on the island. In the *Mining and Scientific Press* for February 25, Mr. Oscar Hershey presented detailed assays showing that 38 samples from the 1450-foot level of the Treadwell mine averaged \$2.50 in gold, 29 from the 1210-foot level of the Mexican, \$3.67, and 26 from the 1350-foot level of the Ready Bullion, \$6.11. In Mr. Robert A. Kinzie's annual reports there are tables presenting similar averages of assays level by level. These show that variation in gold content occurs in depth as along the strike, but there is no consistent evidence of decrease in amount of gold in depth. Indeed what is now available would point slightly in the opposite direction.

In South Africa the matter has been much studied, though details have never been made public. Geological work on the Rand has heretofore been done mainly by men employed by the individual companies, and the observations of any one man were necessarily, therefore, restricted. A systematic public survey of the district similar to that made in Western America by officers of the United States Geological Survey has only recently been undertaken. Evidence from the Rand therefore rests on *obiter dicta* of men presumably basing their statements on adequate information, or upon analysis of output figures. That the latter afford insufficient data for such an investigation has been pointed out by several in the discussion of Mr. C. O. Schmitt's paper recently read before the Chemical, Metallurgical and Mining Society of South Africa. The ore mined is determined by the cost of mining and as the scale of operations increases and practice becomes settled, lower grades of ore become available. Incidentally the mines become deeper, and so there is an appearance, perhaps false, of decrease in gold content with depth. Years ago Mr. Hennen Jennings investigated the matter and is understood to have come to the conclusion that, allowing for all variables, there was on the Rand an actual decrease in gold content with increasing depth. To confirm his conclusions Mr. Ross E. Browne spent two years studying the problem. Mr Browne, we believe, came to the same result as had Mr. Jennings. On the other hand, Mr. H. F. Marriott has recently asserted that on the evidence "of assay values of samples of actual reef widths taken throughout all the mines," of the group controlled by his house, there is "no substantial evidence today to prove a general deterioration in the richness of the ore." Mr. F. H. Hatch stated in his 'James Forrest Lecture,' printed in the *Mining and Scientific Press*, July 22 and 29, "I have not been able, with the material at my disposal, to come to any definite conclusion on this point, but I am inclined to the view that a gradual impoverishment with depth does exist." Mr. Hatch's views have been misinterpreted in South Africa, as is shown by our own Johannesburg letter in this issue. His estimates of the gold content of the Rand bankets were carried to the depth of 6000 feet only, because only the data to that depth were available. His own statement is: "For practical purposes the whole question turns on gold content; and what that may be at a vertical depth of 7000 or 8000 feet no one can tell. This much, however, may be said: the geological structure clearly indicates the continuance of the conglomerate or banket beds to still greater depths than even 7000 or 8000 feet before the bottom of the great synclinal basin of the Witwatersrand is reached; and, beyond that point, the beds must still continue until they rise to form the southern lip of the basin, known to exist beyond the Vaal river."

Evidently competent authorities differ in their interpretation of the facts shown on the Rand, and, in the absence of access to full data, the opinion of an outsider is of little value. It would seem, however, that it is to some extent a matter of interpretation as well as observation, and intelligent interpretation requires formulation of theory. It will not do to decry hypotheses and attempt to rely exclusively upon bare facts. No man can hold in mind enough facts to answer such a question as here proposed and the minute generalization of facts is attempted, theory creeps in. It is a common observation that the 'practical' man who scorns theory has a head most full of wild hypotheses which, however, he mistakes for facts of observation. To answer intelligently the intensely practical question as to impoverishment or enrichment in depth, consistent theory must be used. If the data now available in all the Rand mines be placed in the hands of a competent corps of geologists there should be no great uncertainty as to results.

Geologists have learned of recent years to discriminate sharply between primary and secondary ore deposits. The value of the discrimination has been shown repeatedly, perhaps most strikingly in the aid afforded in development of the porphyry copper deposits of the United States. Secondary ore deposits stand in definite genetic relations to the surface or to some other local phenomenon. The relation may be obscure, but once determined, a flood of light is thrown upon the peculiarities of the orebody. A primary ore deposit, formed before the present surface was sculptured, cannot well be dependent upon that surface, though the latter may still show relations to it. Silicification of a limestone bed occurring in connection with the introduction of ore-bearing solutions when the whole was deep below the surface, may, because of the hardening of the bed, later cause the latter to stand above the general level. This may give rise to an easy but erroneous generalization as to the influence of the surface on the ore. Many similar cases might be cited. To unravel such matters, to discriminate between the coincidental and the genetic, is the province of the trained geologist. With his help it should be entirely possible to reach sure conclusions about probable impoverishment in depth wherever sufficient ground is open to observation.

The Ray Consolidated Copper Company

By Charles A. Dinsmore

The Ray Consolidated Copper Co. owns properties at Ray, Pinal county, Arizona, and a 10,000-ton concentrator at Hayden, 20 miles away. The mine is the largest porphyry copper, in the Southwest at least; and within the 180 acres thoroughly prospected and developed there is 80,000,000 tons of 2.17% copper ore, equivalent to an average of almost 500,000 tons per acre. Development was first by churn-drilling, and later by regular underground methods, and at this time there are more than 36 miles of underground work. This is progressing at the rate of a mile and a half per month. It is interesting to note that the real opening of the mine by underground methods was begun but a little more than a year ago, since when development has been rapid. The ore is generally disseminated throughout an area known to be 7300 ft. in extent east and west and 3000 ft. north and south. The mineral belt considerably exceeds this in length, though it has not been systematically drilled beyond these limits. The average depth of the capping is 315 ft.; the average thickness of the orebody is 171 ft. The western orebody is thicker than the eastern, so that probably 60% of the total will come from the former area. To win 85% of the ore will necessitate hoisting approximately 300 ft., though for a great many years the lift will be only about 170 ft., or to the first level. The property will produce when in full operation about 80,000,000 lb. of copper annually, and the management estimates that this will be done at a cost not exceeding 9 cents per pound of commercial copper. The elevation is about 2000 ft. above sea-level. The caving system of mining is being employed, on the most elaborate scale, and an estimate of 9 to 10 tons of ore per man per shift is conservative. In the successful operation of the present-day low-grade copper properties, the mining costs spell profit or loss absolutely; so, if these be reduced the fraction of a cent per ton, it puts the figures on the right side of the ledger. With the Ray Consolidated the mining costs will be minimized almost beyond belief. The 10,000-ton mill at Hayden is admirably designed and built, so that with both mining and milling costs low, there is no doubt that this property will within another twelvemonth be one of the most important of the copper mines of the United States. At this time the concentrate from the mill is going to Aguascalientes, Mexico; but as soon as the new furnaces are completed at El Paso they will be sent there. The officers of the company include D. C. Jackling, general manager; David Cole, for many years at the head of affairs at Cananea, manager; Louis Cates, who had charge for many years of the Boston Con., mine superintendent; W. S. Boyd, who was with Mr. Cates in Utah, assistant; R. C. Nowland, who for many years has represented Henry Krumb, and who had charge of all the sampling and assaying at Ray during the churn-drilling period, engineer; George O. Bradley, superintendent of construction; A. J. MacLain, cashier; J. H. Brown, purchasing agent; E. J. Franklin, general superintendent of power plants for the Ray Con. and affiliated companies. Hayden is headquarters for the Ray Consolidated.

RAY, APRIL, 1910, SHOWING CENTRAL PORTION OF ORE-ZONE.

The determination of the value of the holding was the work primarily of the churn-drills, of which 13 were employed, including both Star and Keystone machines. Drill-holes were made on the corners of 200-ft. blocks, and 353 holes were drilled. Starting with an 8¼-in. casing, this was tapered first to 6¼, then to 4¼. In sampling, every precaution was made to secure exactness. Every 5 ft. each hole was completely cleaned and the sludge sampled, passing through an automatic sampler invented by Mr. Nowland. To check the work of the local chemist, a composite sample was taken, 20 samples for every 100 ft. These were thoroughly mixed, reduced to proper size, and assay samples sent to outside chemists. In the underground development and exploration, over 1000 ft. of drill-holes have been checked, giving the most wonderful results. The first checking underground was accomplished by driving to and under a drill-hole, [illegible] [illegible] the hole, taking out any bad. Two sets of samples were taken every 5 ft to correspond with the samples during drilling. The results of a comparison of the two checked within a small fraction of a per cent. In the churn-drilling work a grab sample was taken from the top of each bucket of sludge and sampled at once, to give constant knowledge of what the hole was doing. The balance of the sample was sacked, sealed, labeled, and sent to the laboratory for assaying. The regular sample for the 5 ft weighed about 60 lb. Some 25 miles of road was necessary for the transport of the drill machines to the different portions of the property, but much of this road building consisted only of cutting out underbrush and rolling away boulders. Water lines to the drills were of 1-in. pipe and were laid on the surface. The drilling and sampling were done on the most elaborate and careful scale, and this, with the results positived by underground developments, made it feasible to go ahead on the large scale the company has adopted for the mining and reduction of the ore.

The orebody is disseminated in Pinal schist. The schist has been fractured by many faults, and first diabase and then granite porphyry were intruded. Outside the belt of these intrusions, on the north is the Pinal schist, unmineralized; on the south, some schist and some granitic rocks; on the east, sedimentaries, which are intruded by different eruptives; on the west, schist and some eruptives. The orebody is at quite a uniform elevation, lying flat. Some of the drill-holes showed ore in the eastern section at 100 ft. deep, and in the western section sometimes 450 ft. of capping would be drilled before the ore was reached; the difference being due to the fact that in the western section the general elevation is greater than in the eastern, while the orebody lies at the same elevation in each district. The greater bulk of the ore shows copper disseminated in Pinal schist, generally in the form of chalcocite, sometimes chalcocite accompanied by cupriferous pyrite. Locally, there has been found but little cuprite or native copper, and practically no carbonate or silicate. The capping even is practically free from carbonates. The line of demarcation between the ore and the capping is very abrupt. In drilling, the bit often went from oxidized material having no value into good ore within 5 ft. A few acres of good ore has been found in the No. 1 mine in a laccolith of granite porphyry. This laccolith is entirely surrounded by ore-bearing schist. Considerably smaller areas of diabase in the form of dikes have also been found to contain good ore. The highest point of drilling so far was near the crest of Humboldt hill, where 450 ft. of capping was pierced. Under this hill is an orebody of approximately 1,000,000 tons per acre. The mineral belt is easily traceable on the surface, due to its high color, the red stain of hematite, together with the kaolin and the sericite, both of which are the results of decomposition of the muscovite mica. The mineralized belt differs, too, from the non-mineralized, in that the latter is a dark grayish rock, much harder and more compact than the former.

Operations will be conducted through working openings in what are called the No. 1 and No. 2 mines. At each of these there is a long adit arranged for transportation of ore. No. 1 is at this time 1300 ft. and No. 2 approximately one mile in length. The location of all work is at this property designated by sea-level elevation—thus, No. 2 is called 2090, No. 1, 2020, these figures representing actual elevation. At each of these points there is a vertical shaft, through which all ore is handled. From each adit-level there is an incline at about 36° to the main underground traction level. Down these inclines wide stairways have been constructed, these being used by the men, no employees riding. The head-frames are steel, each hoist is identical, the daily normal capacity of each being 6000 tons, handled in $12\frac{1}{2}$-ton skips. These are probably the two largest electrically-driven hoists in the country. They are described in detail on another page. No. 1 equipment is complete and in operation, while at No. 2 the machinery is being erected. The No. 1 mine has the greater amount of development, and work identical to it is going forward at the No. 2. Each level is developed exactly as the one above. Except in the traction ways no timbers are used. The method of handling the ore is interesting. The underground ore trains are of 12 cars, each having 5 tons capacity. The electric engine brings the train to the tipple and through it, leaving the last three cars. These are automatically fastened in the tipple, and the tipple turns, dumping the loads into a bin over an incline. The cars are then shunted out, and three more run in, and so on until the entire train of ore has been dumped. The ore-bin beneath the tipple is of concrete. The cars have no doors, nor openings at the side or end, but are simply steel boxes containing 5 tons. They are equipped exactly as are the freight cars on transcontinental railways, with straight air brakes and M. C. B. couplers. From the bin, by means of air-operated steel gates, the ore is dumped into gauge hoppers containing a full load for the skip. The skip is lowered below the gauge, when the bottom of the hopper is pulled out and the load instantly drops into the skip. The skip is brought to the surface and dumped into a receiving bin. Here, also by means of air-operated steel gates, the ore is sent over grizzlies and into No. 8 Gates gyratory crushers by gravity. From the gyratories the oversize goes to two sets of Garfield rolls, 72 by 20, these two processes dressing to 1 inch. Below the rolls there is a traveling belt which takes the ore to a carrier belt, which distributes the material into the bins, the latter having a total capacity of 20,000 tons. There are three railway tracks beneath these bins, the trains being run under and loaded by means of hand-operated gates. The dressing of the ore to proper size for milling is somewhat unique for this region, and the plan adopted is very economical. No handling is necessary at the mill, better and quicker work is done, and the cars receive the maximum load with no unfilled spaces. Power for all this, for the machines, for the haulage-engines in the mines, for lighting, and other purposes, is generated in the power-plant at Hayden. The power-transmission line is excellently built, steel towers being used.

At Ray may be seen the most advanced application of the caving system, on a large scale. The essential points here are to cave in such manner that the capping will not crumble and thus become mixed with the ore, and to win large quantities of ore constantly. Every move is exactly determined before it is undertaken; and throughout the mine all tracks are laid to grade, the same as on transcontinental railways. The initial point is numbered zero, and all operations numbered from that point, the same as the laying out of the streets in many cities. Thus the first opening off the tramway will be 1 S., 1 E., or 100 ft. south and east of zero, and so on. The sill-floor of each stope is 25 ft. above the traction level, and each stope is given a figure showing its position with reference to a central point. The thing is simple, but the practice here is to simplify this simplicity. In the laterals, manways are driven upward every 100 ft. to the capping, and through these the miners pass into the stopes at convenient points. The stopes are 30 ft. wide, leaving pillars of 20 ft. of ore. The miners strip the sides of the stope, and after blasting, the backs come down without further work. The ore is seamed and friable. The stope is carried to the capping, and the pillar holds the capping. Large areas are so stoped, only a small portion of the ore being drawn. This is removed in order to assist in the breaking down of the backs with the shoothing of the side holes, the weight of the ore aiding this process materially. When the time comes for drawing the ore from the stopes, small stopes are driven upward in the pillars 20 ft., and on either side a great many holes are drilled. These are shot in rotation during one shift, the result being that the base of the pillar is undermined completely. Then the car-men are put to work drawing ore, there being two chutes from each stope, one on either side of the track, and a chute for the pillar stope. The quantity of ore in the ground being caved is known almost exactly, so there is no guesswork about drawing out the supply. In drawing the ore a smaller portion is taken from the rear end of the stope than from the front. This permits the ore and the capping to settle uniformly and in conformity with the contour of the ground originally, and thus the capping is kept entirely free from the ore. To be certain that the ore is drawn as it should be, a central station is maintained, which every car must pass. Here the checker takes the number of the car, whence it was filled, and the name of the man in charge, thus keeping all records. An idea of the small quantity of waste may be learned from the fact that there are two bins, one for the ore and one for the waste, the former of 20,000 tons capacity, the latter 500 tons. In order to see exactly what this method was doing, an engineer watching the stoping operations crawled to the top of the stope from which the pillars had been released, and he found that the capping was from two to many feet above the ore the entire space of the stope—that, in fact, practice followed theory closely. By this caving system the amount of ore possible of extraction per man is enormous as compared with lode mining. The economy is here enhanced also by the fact that the ground is solid, the pillars holding well, and thus not a stick of timber is needed in the stopes, except for the chutes.

The surface equipment at Ray includes a complete machine-shop, with appliances for all ordinary work; carpenter-shop, warehouse, and other buildings. The sub-station where is received the electric voltage from the Hayden power-plant is very complete. The power comes over at 45,000 volts, and the high-voltage plant is on a balcony of the plant, completely isolated. The voltage is stepped down to 440 for power and 110 for lights. There is a 300-hp. motor generator set 440 A.C., 250 D.C. The switchboard serves the entire plant. There are two Allis-Chalmers motors, each of 500 hp., driving two Nordberg high-efficiency compressors, 3000-cu. ft. capacity each.

The concentrator at Hayden is now operating three units of what is to be a 10,000-ton plant of eight units. Other units are being built as fast as a large force can accomplish it. The building is steel frame, 378 by 400 ft. over all, and it is arranged for efficiency and convenience. I shall describe the flow of the material through but one of the units. The others are duplicates. The ore from Ray comes down in 60-ton Ingoldsby steel cars, and is dumped directly into steel bins of 25,000 tons total capacity. From bin it goes to a conveyor-belt, bringing it to a 30-in. 15-bucket elevator, which takes it to six impact screens of 7 and 8 mesh. The reject goes to two 16 by 42 Garfield rolls (dry crushing), regrinding it till it passes through the screens. The undersize goes to six Garfield roughing tables. Heads from the tables go back to an elevator and are discharged to a 4-compartment Janney classifier, the primary, where it is classified and returned to Garfield Chilean mills, grinding through two No. 77 screens. The overflow from the primary classifier goes to 10 cone-tanks, this feed going to Isbell vanners. The second compartment of the classifiers discharges to second classifiers, 4-compartment, and this feed goes to Isbell vanners with corrugated belts. The feed from Chilean mills goes to 3-compartment improved Janney classifiers, which feeds to four Garfield roughing tables and to Wilfley tables; on the Wilfleys the first concentrate and tailing are made. The overflow from secondary classifiers goes to 10 cone-tanks, and this feed to Isbell vanners with smooth belts. The overflow from mill classifiers goes to 10 cone-tanks, is syphoned off, and the pulp taken for the different vanners. The tailing goes to the tailrace, being automatically sampled every 30 minutes. The concentrate goes to receiving tanks under the mill, is elevated by centrifugal pumps, passes through automatic samplers, and so to the concentrate bins. There is a filter in each bin and a vacuum-pump takes the water out and puts it again into circulation. Concentrate is loaded into cars by a Morgan 10-ton Gentry crane. The ratio of concentration is 20 to 1. The overflow from all the cone-tanks is purified and pumped back to circulation, being used on classifiers and roughing tables for wash and feed water.

The line-shaft actuating the crushers and Chilean mills is beneath these machines and extends the entire width of the building. Rolls are on one side of the shaft on the floor above, and mills on the other side. Clutches, operated by air, start or stop any portion of this section of the mill. There is a 30-in. belt and a double row of 15 by 8-in. buckets. The sampling plant is at one side of the mill and is complete. Here all samples are taken and the pulps sent to the laboratory, a short distance away. The milling plant is very complete, well lighted, and is doing excellent work.

The pumping station is situated just below the confluence of the San Pedro and Gila rivers, about one mile from the mill. Wells have been sunk supplying clear water, which would not be the case were the water taken from the rivers or from ditches. There are three Aldrich quintuple special pumps, directly operating by induction motors, this equipment having a capacity of 10,500 gallons per minute per unit. The service reservoir for the plant holds 8,000,000 gallons, and the pumps are connected with 26-in. wooden pipes. The pumps are sunk to natural water-level.

The power-plant is one of the finest in the country. E. J. Franklin is general superintendent of power-plants for the affiliated companies; Henry Ruark is chief engineer at Hayden, and W. B. Clement, assistant. The normal capacity of the plant is 7000 kw., but it is capable of heavy overload. The equipment includes four Allis-Chalmers type E, 4-cylinder, triple-expansion engines of 1750 kw. each. There are a high-pressure and a low-pressure cylinder on one side, an intermediate pressure and a low pressure on the other side. The engines run 100 r.p.m.; steam pressure is 175 lb.; superheat between 50° and 75°; size of cylinders, high-pressure, 28 by 48 in.; intermediate, 52 by 48; low, 54 by 48. Alberger surface-condensers, two on each engine, on account of the low-pressure cylinder, one for each side. These are the largest engines of the kind, though there are many larger of the cross-compound type. The steel fly-wheel is made in four parts, weighs 55 tons, and is 26 ft. in diameter, with a rim speed of 8168 ft. per minute, or, at this rate, it would roll more than a mile and a half per minute. Each engine generates about 3000 maximum horsepower, and when it is stated that the ordinary locomotive running 60 miles an hour uses about 1700 hp., the size of these engines may be better understood. Each engine operates an alternating-current generator. The diameter of the roter over all is 23 ft. When I visited the plant the engine operating was pulling a 50% overload without trouble.

There are also two Nordberg tandem compound-exciter engines; cylinders 13 by 23 and 36; 100 r.p.m.; one Allis-Chalmers generator set; one Nordberg triple-expansion, high-duty pumping-engine; cylinders, 12 by 24, 36 and 36; capacity, 10,000,000 gal. per 24 hours. The water is in part first used for the condensers in the power-plant, and then goes over a set of cooling towers. The big pump takes it from the basin under the towers, pumping into the 8,000,000-gal. reservoir which supplies the mill. There are three cooling towers of Ray Con. design, and several more are to be built.

There are one Nordberg cross-compound, piston, blowing-engine, 8000 cu. ft. capacity; 14 Heine boilers, 513 hp. each, equipped with Foster superheaters; 4 Blake compound, boiler-feed pumps; and 3 Foster feed-water heaters.

The main and auxiliary headers and all valves and fittings are steel. The plant will develop largely in excess of stated capacity, and, in fact, when everything is running smoothly and to full capacity, there will doubtless be an idle engine, ready for emergencies.

The machine-shop equipment at the Hayden plant is exceptionally good. It includes 4 lathes; milling machine; planer; shaper, 2 drill-presses; 3 pipe machines; 2 belt-cutters; 1 grinder. Two additional lathes and a boring machine and press are en route. The blacksmith and boiler-shop is also furnished with every appliance needed. The carpenter-shop is close by and equipped with the necessities. In fact, no detail of this end of the business has been overlooked nor has any been neglected.

The staff house where the manager and heads of departments take their meals, is a handsome building, beautifully furnished, and the meals are excellent. The cost includes no profit to the company, but it is maintained as carefully as a fine hotel. The similar house at Ray is also excellent, and the service equal to that at Hayden. The mill at the Ray Consolidated at Hayden is as handsome a structure as I have ever seen, and the machinery is the best. The fact that the concentration is 20 to 1 proves efficiency. The whole planning of this mill was so correct that practically no changes have been made, and the building itself was exactly what was needed. The construction of additional units goes on with the regular operation of those in commission. This mill building and the first units were put into commission in record time. When, within a few months, the entire plant shall be in operation, with 10,000 tons of ore going through daily, there will certainly be a concentrator worthy more than cursory attention. G. O. Bradley was the designing engineer.

I must express my sincere appreciation of the kindnesses accorded me by the management. I was permitted to go where I would and when I would, ask questions and receive information. These courtesies coupled with others, including entertainment in the handsome and well arranged and furnished guest houses of the company, were all extended so freely and so heartily that I really felt at home, as I am sure was the desire. All this clearly indicates that the Ray Consolidated management has solved its problems, and that there is, and is to be, nothing here but mining on the most scientific and strictly business basis.

Refining Metals

Unless metals are of high purity they are usually of little usefulness, says Joseph W. Richards. Electrolytic methods enable almost perfect purity to be easily attained, and in addition permit the separation at the same time of the valuable gold and silver contained in small amount in the baser metals. Over $100,000,000 worth of copper is electrically refined every year in the United States; it is purer than could be otherwise obtained, giving the electrical engineer the highest grade of conducting metal, while several million dollars' worth of gold and silver are recovered which would otherwise have to be allowed to remain in the copper. Again, the method is so simple that but a few words are necessary to set it forth in principle. The impure copper is used as one electrode—the anode—in a solution of copper sulphate containing some sulphuric acid; the receiving electrode—the cathode—is a thin sheet of pure copper, or of lead, greased. The electric action causes pure copper only to deposit upon the cathode, if a properly regulated current is used, while a corresponding amount of metal is dissolved from the anode. Silver, gold, and platinum are undissolved, and remain as mud or sediment in the bottom of the bath; other impurities may go into the solution, but are not deposited on the cathode if the current is kept low. The cost of this operation is small, and the results are so highly satisfactory that 90% of all the copper produced is thus refined. Similar methods are in use for refining other metals. Silver, gold, and lead are thus refined on a large scale; antimony, bismuth, tin, platinum, zinc, and even iron can be thus refined. The field is very inviting to the experimenter and to the technologist, and is rapidly increasing in industrial importance.

An examination of the Porcupine district was recently made by A. G. Burrows for the Ontario Bureau of Mines. Mr. Burrows effectually disposed of the value of the sensational samples, on which the excitement concerning Porcupine was worked up and fed for a long time, by saying: "The distribution of the gold is generally irregular, occurring along one or both walls, while other portions of the vein may be very low grade. Most spectacular showings occur on many properties, but these are limited to portions of the veins. Considering the irregular character of certain veins and the quantity of the country rock which will need to be mined, the ore must be considered low grade."

Amur Gold Regions

St. Petersburg Correspondence

A Russian mining engineer who has visited the Amur gold regions states that an investigation of the Upper Sei river which rises in the Sei mountains and finds its way into the Amur at Blagoveshtchensk has shown that the gold-bearing region extends only between 55° north latitude and the river. North of this line stretches a mountainous country. Southwest there is low undulating ground on the upper part of which near the Sei have been found remnants of gravel deposits. The northern part of the country is non-auriferous, while in the southern part several concentrations of gold have been found sufficiently rich to make their exploitation profitable. The line of most intensive volcanic activity is found farther to the west on the same latitude and has been followed to the Gilya. But in the western part of the region the difference in character of the country becomes less pronounced; and finally beyond the Dzheltul it disappears almost entirely. South of the line noted gold has been produced in many places. The richest gold region is that of the Ulyagir Sugdzhari. East of this placer gold has been found on the Kinlyandzhak and in several places on the Kupuri where gold occurs in pyrite. This zone should stretch farther east to the limits of the basin of the Uda. If the western part of the zone described may be considered relatively known, the eastern part is practically unknown, which must be ascribed to the difficulty in reaching it, that is, to the absence of roads. The same may be said of the districts west of the Upper Gilya.

To the south the gold-bearing zone is much richer and dotted with mines. It stretches along a high range of mountains from the Dalny Taig and Tukuringra to the Upper Tungir and beyond. Its extension eastward constitutes a high watershed between the Amgun and the Selemdzha on the one hand and the Udom on the other. In close proximity to these ranges, reaching from one slope to the other, are the well known mining districts, the Verchne-Selemdzhinska, Unya-Bomskaya, the Sei, and the Dzhalinsky. The bedrock in the first and the third districts consists of granite and gneiss; in the second and fourth it is granite and metamorphosed schist. The Amgun and Nieman districts and the river Chargi are in the same vicinity. The first of these districts extends over a great length. The second stretches west-northwest and both zones come close together on the Upper Gilya. Between the Upper Sei and the Dalny Taig they are separated by about 100 versts (66 miles), where a great hollow has been formed filled up with relatively recent deposits, among which, in all probability, in many places gold sands will be found. Prospecting here, however, is difficult. In the western part of this depression, that is the Lower Bryanta Utugeaya and Unachi, these deposits are not particularly heavy, thanks to which it has been possible to employ dredges. Within the limits of the lower Sei gold-bearing region, as well as farther east, between it and the Lower Selimdzhinsky, in the basin of the Mamyna, and of the Gari, discoveries may very well be made. Gold, indeed, has been reported near various tributaries on the right bank of the river Gari.

It may be interesting to point out an immense region stretching from the upper Toma through the Bureya into the Upper Gari, the Tyrmi, the Upper Urma, the Karu, and the Amgun through Goryn to the lake district of the Lower Amur. Here, according to report, gold in profitable quantities has been found. The geological conditions are favorable in part; but the most interesting parts of this region must be considered up till now among the most difficult of approach in the whole area and have attracted little attention. With the building of a railway the Upper Solokatcha Tyrmi and the regions south of the right tributaries of the Urma begin to be accessible.

The Electrical Precipitation of Suspended Particles

By F. G. Cottrell

*The next plant in order of size that was undertaken was at the Balaklala smelter at Coram, Shasta county, California. The vast body of low-grade copper ore reaching for many miles across this county and commonly known as the copper crescent has recently been described in detail by L. C. Graton[12] and characterized as the second largest copper deposit which can be considered as a single geological unit in the United States. The first commercially successful smelter in this region was erected at Keswick in 1896 by the Mountain Copper Co., Ltd., under the management of Lewis T. Wright, and was of especial interest as one of the pioneers in pyritic smelting. Extensive heap roasting was also carried on at this plant, with the result of widespread deforestation of the surrounding country and the final closing down of the plant in 1905 through injunction proceedings instituted by the U. S. Forest Service. The company has since built a small smelter and acid phosphate works at Martinez on San Francisco bay and now ships its ore to this point, nearly 250 miles distant, for treatment, but even this latter plant has at various times come in for its share of fume litigation.

In 1901 the Bully Hill smelter at Delamar, with a capacity of 250 tons per day, was started. This was later purchased and is now owned by the General Electric Co., but since last July it has been closed as a result of complaints by the U. S. Forest Service, which insisted, at that time, that the plant either close or at least commence efforts on a practical scale looking toward controlling its fumes. In 1905 the Mammoth Copper Mining Co., a subsidiary of the United States S. R. & M. Co., blew in its present smelter at Kennett. This plant, when running full, has a capacity of some 1200 tons of ore per day. The Balaklala, which belongs to the First National Copper Co., is the most recent of the Shasta county smelters, having blown in its first furnace in 1908.

These smelters are all situated in the narrow, precipitous cañon of the upper Sacramento river and its tributary, the Pit. The region itself is too steep and rocky for agriculture, but was once heavily wooded, although now swept bare of vegetation for miles. As far as the cañon itself is concerned, probably all the damage possible has already been done, unless reforestation were undertaken. This latter even would probably be slow and difficult work, as, since the loss of vegetation, the steep hillsides have been washed bare of soil for miles around. At Redding, however, some 13 miles below Coram and 17 miles below Kennett, the cañon widens out into the fertile Sacramento valley, and from this point southward, for some 12 miles farther, lies the region from which for the past two years have come increasingly insistent complaints against the smelters. These culminated, a little over a year ago, in agreements between the farmers and the smelters under which friendly suits were brought in the Federal courts and injunctions issued by stipulation requiring the smelters to remove the suspended matter from their exit gases and dilute the latter to such an extent that their sulphur dioxide content should not exceed 0.75% by volume as discharged from the stacks, with the further general and sweeping provision that they should do no damage.

To accomplish this the Mammoth smelter built a bag-house which has been in successful operation since July 1910. The gases discharged from the five stacks (each 21 ft. square) are, to all intents and purposes, free from suspended matter and consequently invisible. This represents a notable achievement, being the first time that the bag-house, so efficient in lead smelters, has been successfully applied to copper blast-furnace gases on the large scale. It is made possible in this instance through neutralization of the sulphuric acid in the gases by the zinc oxide carried over in the fume from the zinc content of the ore smelted. The company is also the owner of patents[13] on the introduction of finely divided metallic oxides into the gases for this purpose. In addition it was necessary to provide an extensive system of cooling pipes in front of the bag-house. There are 39 of these pipes, each 4 ft. in diameter and averaging about 200 ft. in length. They represent a large part of the cost of the plant. It was expected that they would be sufficient to cool all the gases of the plant to a safe temperature to protect the $30,000 worth of woollen bags with which the house is filled, but upon starting it was found that only a little over half the full capacity of the plant could thus be treated with safety, and operations were accordingly restricted to this. In the cold weather of winter a considerably larger tonnage can be handled with safety than during the hot summer. Notwithstanding this, however, the bag-house is to be considered a decided success; at least for the particular conditions met with at this plant, and the management deserves great credit for the courage and skill with which it has carried through this new, and after all largely experimental, undertaking, representing as it does the expenditure of over a quarter of a million dollars.

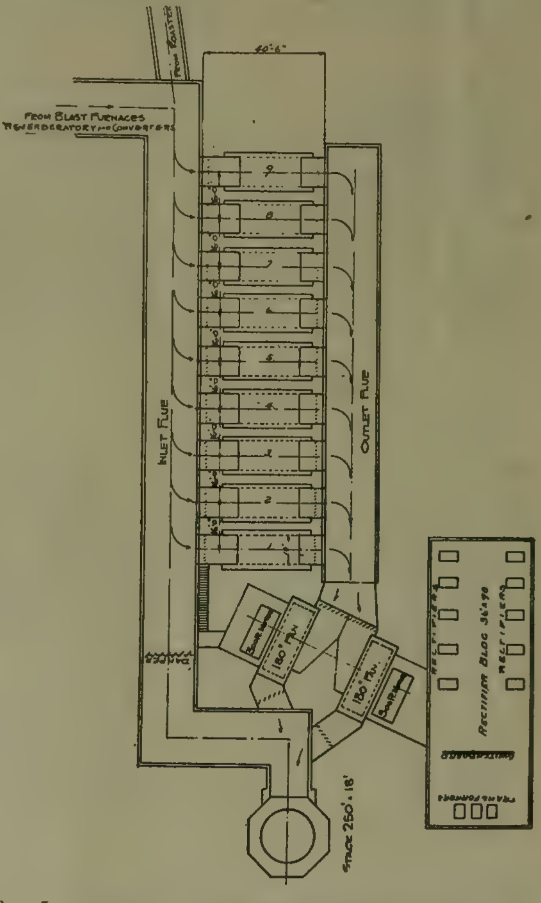

Fig. 5. GENERAL ARRANGEMENT OF PRECIPITATING PLANT, BALAKLALA CON. COPPER CO., CORAM, CALIFORNIA.

---

*Abstract from *Jour. Ind. & Eng. Chem.*, August 1911, and continued from *Mining and Scientific Press*, page 255.

[12] U. S. Geol. Surv., Bull. 430b.

[13] Clarence B. Sprague, U. S. Pat. 931,515, Aug. 17, 1909, and 984,498, Feb. 14, 1911.

In the case of the Balaklala smelter, the use of a bag house was also considered, and in fact a small experimental unit containing a few bags was run for some months in comparison with tests made by the electrical process here described, and also a centrifugal apparatus in which the gases passed through a rapidly rotating cylindrical shell equipped with radial baffles to insure the gas being raised to full velocity. As a result of these tests the electrical process was adopted for the full-sized installation.

The smelter treats from 700 to 1000 tons of 2½ to 3% copper ore containing over 40% sulphur with considerable but varying amounts of zinc. The greater proportion of this is handled in blast furnaces, but the fine material, including everything under ¾ in. and amounting to less than 10% of the whole, goes through McDougall roasters and an oil-fired reverberatory. The plant has also two converter stands. The gases from all these departments pass into a common flue, 18 by 20 ft. in cross-section. The volume of gases passing through this flue varies with operating conditions from a quarter to half a million cubic feet per minute, which means, in round numbers, a mean linear velocity in the flue of 10 to 20 ft. per second.

Before attempting to design the full-sized equipment for treating these gases a small precipitation-chamber capable of treating about 1% of the total gases, was erected and an extended set of experiments made with it. With this miniature unit as a guide, the equipment of the whole plant with similar apparatus was undertaken in March 1910. This was completed and first put into operation at the end of the following September, since which time it has been in continuous operation, with the exception of the latter half of December, when changes were decided upon, during completion of which it became necessary, under the terms of the court decree to shut down the plant for a couple of weeks. As was naturally to be expected, many difficulties were encountered, some of which have already been entirely overcome, while others are giving way more gradually before the systematic study of operating conditions. Fig. 5 is a plan of the nine electrical precipitation-units or chambers in their relation to the flue system and stack. It should here be noted that the two large fans indicated in the drawing are not required for the operation of the precipitating system nor to overcome any added resistance due to its introduction, as this latter is slight. The fans were made necessary by that section of the court's decree requiring dilution of the sulphur dioxide to 0.75% or less. When the furnaces are running on a high sulphur charge this feature of the decree necessitates a considerable dilution of the gases with fresh air and corresponding diminution of stack draft. At these times the fans are operated, but during a considerable portion of the time the sulphur dioxide in the gases can be brought low enough without interference with the draft, and during these periods the fans are stopped entirely, although the gases still pass through them.

At the rectifier building the current is received from the companies' three-phase power-circuit at 2300 volts, 60 cycles, and after being transformed up to from 25,000 to 30,000 volts under the control of the operator through the variable resistance and induction regulators, is rectified into an intermittent direct current, as already explained, and distributed to the individual precipitating units. Fig. 6 shows a cross-section through one of these units or precipitating flues as first installed. The double vertical lines represent the collecting or grounded electrodes, each 6 in. wide by 10 ft. high, made of No. 10 sheet iron. The dotted lines represent the discharge electrodes, consisting of two iron wire strands between which is twisted the discharge material, for which both asbestos and mica preparations have been used in this plant. Each unit contains 24 rows of 24 electrodes of each type. The collecting electrodes are carried by bars connected directly to the frame of the chambers themselves, while the discharge electrodes are supported by springs between a system of buss bars carried on externally placed insulators as shown in the figure. To the auxiliary chambers surrounding these insulators a small regulated amount of air is admitted to prevent conductive dust or fume from working back and settling on the insulators. The cam and shaker rod extending across the middle of the unit was originally designed for the purpose of vigorously shaking the electrodes, as it was greatly feared that the removal of precipitate from the electrodes in units of this size might be one of our most serious problems. In actual operation it has been found, however, that the electrodes can easily be shaken entirely free from dust by hand from the top; the whole operation, including cutting the unit in and out of the system and the removal and replacement of its covers, requiring only about ten minutes, and this having to be repeated every six or eight hours, depending on the dust content of the gases. The precipitated dust and fume as it falls from the electrodes is carried by the conveyor in each unit to a common longitudinal conveyor which in turn discharges into cars carrying it away for treatment.

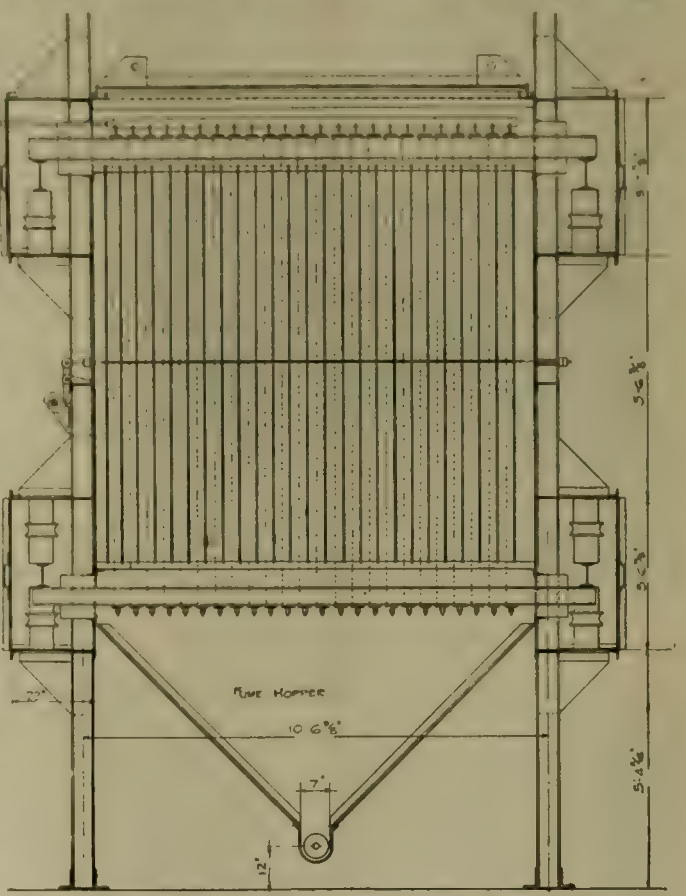

FIG. 6. SECTION THROUGH PRECIPITATING PLANT OF THE BALAKLALA CON. COPPER CO., CORAM, CALIFORNIA.

Filtration tests show that this plant, under favorable working conditions, precipitates between 80 and 90% of the suspended matter in the gas, the average over the whole period of operation to date being somewhat less. Under present operating conditions at the smelter, this represents some 6 to 8 tons of precipitate per 24 hours. The gas-treating plant as a whole, including flues, fans, motors, and electrical apparatus, cost, up to the time it was put in operation, a little less than $110,000. Although many minor changes have since been made, none of the larger or more expensive elements of construction have been greatly altered.

The total average power-consumption for the precipitation-plant when running is in the neighborhood of 120 kw. One man can readily control the whole operation in the rectifier house, although, as a matter of precaution for a new plant under the high tension here used, two have usually been on duty. Two laborers and a foreman are employed on the precipitating units and dust-handling system, although this can probably be reduced somewhat by automatic shaking devices, since as yet the main efforts at improvement have been directed elsewhere. The volume of gases to be treated varies considerably with the conditions at the furnaces, but at present may fairly be taken as averaging between 200,000 and 300,000 cu. ft. per minute, and entering the units at from 100° to 150° Centigrade. Fig. 7 is the interior of the rectifier house or control station, showing the general arrangement of apparatus and wiring.

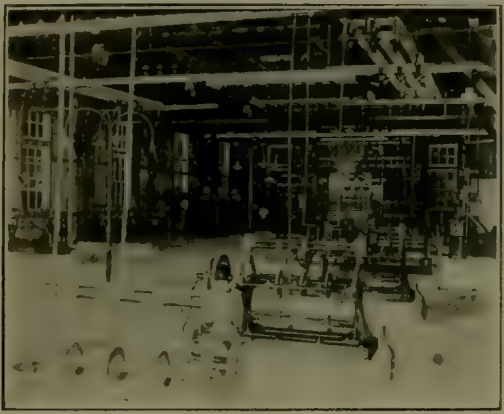

FIG. 7. RECTIFIERS AND WIRING OF DYNAMO ROOM.

One of the greatest difficulties met with at this particular plant has been the maintenance of conductivity in the fine fibres of the asbestos and mica of the discharge electrodes. At ordinary room temperatures these materials readily take on enough moisture from the air to afford sufficient surface leakage for all the discharge necessary, and the same is true at higher temperatures if the gases contain traces of sulphuric acid or other conductive matter, but in the particular gases here met with, the high and variable amount of zinc oxide at times robs them of all conductive matter, thus reducing the conductivity of the fibres of the electrodes and seriously affecting their efficiency. The possible methods of overcoming this and giving the fibres a permanent conductivity of their own, as well as other details of the more purely electro-technical matters underlying the whole process, will be treated more at length elsewhere, as the present article is intended more as an outline sketch of the history and practical development of the work thus far accomplished. Nor is this the place to speculate upon the final outcome of the situation between the farmers and the two great smelting plants which have adopted the remedial measures above described, for this is in the end a question for the botanical and agricultural expert, as to whether or not, or to what extent, actual damage is still being done, no matter whether this comes from suspended matter or from the sulphur dioxide, which neither the bag-house nor the electrical precipitation make any claim to remove. The two smelting companies have done and are doing everything in their power to better the conditions, while, on the other side, the farmers, through the executive committee of their protective association, have earnestly tried to carry out their part in a spirit of fairness to all concerned.

To those who know the circumstances of the many bitter conflicts between farmers and smelters all over this country, with the attendant expense and usual barrenness of results, the present developments in Shasta county present a very suggestive illustration of what may be accomplished in the technical development of our industries by spending the money on experiment and construction instead of all on litigation. Irrespective of the local issues involved, the work done at both of these smelters during the past year has been a real and decided step forward in practical metallurgy. Both plants have already sufficiently demonstrated the applicability to large-scale operation of the principles underlying them to ensure these principles finding a permanent place from now onward in the field of engineering, and each for the particular cases for which it is peculiarly adapted. Before us, of course, still looms the question of the sulphur dioxide, and the solution for this on an equally large scale is, unfortunately, not yet clearly in sight. Before leaving the subject, I cannot but make grateful acknowledgment to those who have worked so earnestly and loyally shoulder to shoulder during the past year and to whose energy and ability such measure of success as has been met with thus far is entirely due. Especially do I wish to express appreciation of the courage, determination, and ability of R. T. White, until recently general manager for the Balaklala company, and now holding the corresponding post with the Braden Copper Co. in Chile, in undertaking and carrying through this new developmental work with all its attendant risks under the most trying of circumstances.

Since the manuscript of the above was sent to the printer, the case of the Balaklala company *versus* the Shasta farmers has come up for formal hearing in the United States Circuit Court in San Francisco, before Judge Morrow, on June 19. The evidence presented from the farmers side consisted of a considerable number of affidavits from individual residents of the district in question, stating that they believed damage was still being done. They naturally made little or no attempt to distinguish between damage from gases and that from suspended matter. Of much more interest in the present connection was the report from Messrs. Gould & Burd, the chemists employed by the Shasta County Farmers' Protective Association, to examine the operating conditions at the smelter itself and determine to what extent the terms of the decree were being fulfilled. Their tests extended over the period from March 10 to April 3, and credit the electrical apparatus with removing during that period an average of 72.8% of the total solids in the gases entering it. In nearly one-third of the individual determinations, the removal of solids reported is over 85%. They report the average concentration of sulphur dioxide as 0.56% by volume, but state that several times during the month the concentration rose slightly above the 0.75% prescribed as maximum by the court. The outcome of the hearing was the entering of a judgment by agreement and stipulation between the contesting parties whereby the plant was allowed 35 days, under existing conditions, in which to run through the ore on hand, but was then required to close completely until such time as it can live up to the letter of the original decree, that is, remove *all* solids, never exceed 0.75% sulphur dioxide, and do no damage. During the time in which the plant still remained in operation, experimentation was carried on as vigorously as ever, with excellent results.

Of the other possible applications of the process, one of the most recent to be actively prosecuted is the collection of dust from portland cement kiln gases. The chief stimulus to this development has again been the nuisance to the surrounding population and its attendant litigation. This has been especially acute in southern California, where several cement plants are situated in the heart of an exceedingly rich orange country. In the case of the Coulton plant, with a capacity of 2500 bbl. per day, an injunction has already been issued by the court which, if sustained, will close the plant, unless they can control their dust, which the court estimates at present at some 20 tons per day. This case differs from that of the smelters in that here there is no question of damage from gases, but merely the deposition of a large tonnage of impalpable dust of lime and clay. From the technical side, a new condition is here met in the high temperature of the gases to be treated, which are 150° C. and upward as they leave the present stacks. The dust itself is, furthermore, entirely devoid of electrical conductivity, but notwithstanding this, it is easily and completely precipitated by the electrodes when these are properly adapted to the new conditions. Experiments on a scale of a few hundred cubic feet per minute were carried on for a few months under the direction of Walter A. Schmidt, at the Riverside portland cement works, and on the basis of these a plant is now being erected to treat the dust from these kilns.

Another extensive field in which it is hoped this process may find useful application is the cleaning of iron blast-furnace gas for use in gas-engines. Outside of the poisonous and combustible nature of these gases, and the consequent necessity for keeping the whole apparatus gas-tight, there would appear to be no new difficulties here to overcome, and steps are being taken to thoroughly test the matter on a practical scale, this work at present being in direct charge of L. L. Johnson, of Indianapolis. A question which naturally presents itself is whether this work has any bearing upon the coal-smoke problem of large cities. In answer, it may be said that for the great majority of cases at present the more logical line of attack would seem to lie in improved methods of combustion, to avoid making smoke in the first place, but in some special instances where such methods may happen to be particularly difficult of application, and the suppression of smoke is especially desirable, electrical precipitation may eventually be found of use, for experiments show that it acts upon ordinary smoke in essentially the same manner as upon the fumes and dust above discussed.

Specifications for Spelter

Standard specifications for spelter were drawn up for the American Society for Testing Materials, by its Committee B-2 on non-ferrous metals and alloys, of which William Campbell, professor in Columbia University, is chairman. These were submitted to the annual meeting of the society, which voted to refer them to a letter ballot. They are as follows:

1. Under these specifications virgin spelter, that is, spelter made from ore or similar raw material by a process of reduction and distillation and not produced from reworked metal, is considered in four grades, as follows: A, High Grade; B, Intermediate; C, Brass Special; D, Prime Western.

2. A brand shall be cast in each slab by which the maker and grade can be identified.

3. The maker shall use care to have carload of as uniform quality as possible.

4. *A. High Grade.*—The spelter shall not contain over 0.07% lead, 0.03 iron, 0.05 cadmium. It shall be free from aluminum. The sum of the lead, iron, and cadmium shall not exceed 0.5 per cent.

B. Intermediate.—The spelter shall not contain over 0.20% lead, 0.03 iron, 0.50 cadmium. It shall be free from aluminum. The sum of the lead, iron, and cadmium shall not exceed 0.5 per cent.

C. Brass Special.—The spelter shall not contain over 0.75% lead, 0.04 iron, 0.75 cadmium. It shall be free from aluminum. The sum of the lead, iron, and cadmium shall not exceed 1.20 per cent.

D. Prime Western.—The spelter shall not contain over 1.50% lead, 0.08 iron.

5. The slabs shall be reasonably free from surface corrosion or adhering foreign matter.

6. Not less than ten slabs shall be taken as a sample from each car; for smaller lots, in the same proportion to the total number, but in no case less than three slabs. In case of dispute, half of the sample is to be taken by the maker and half by the purchaser; and the whole shall be mixed. The slabs selected as samples are to be sawed completely across and the sawdust used as a sample. In case no saw is available for this purpose, the slabs should be drilled completely through, and the drillings cut up into short lengths. The saw or drill used must be thoroughly cleaned. No lubricant shall be used in either sawing or drilling, and the sawdust or drilling must be carefully treated with a magnet to remove any particles of iron derived from the tools.

7. *Lead.* For the determination of lead in High Grade not less than 25 gm., in Intermediate not less than 15, in Brass Special not less than 10, and in Prime Western not less than 5 gm., shall be taken, that is, the sample used for analysis should not contain less than 0.01 gm. lead.

Iron. The sample for iron should contain not less than 25 gm. for the three higher grades and not less than 10 gm. for Prime Western. The entire sample must be dissolved, the iron precipitated as ferric hydroxide, then re-dissolved, reduced, and the iron determined by titration.

Cadmium. Dissolve 25 gm. in 330 c.c. of a solution of one part of hydrochloric acid (specific gravity 1.2) and five parts of water. Let it stand over night; filter and wash; reject filtrate and dissolve the residue, which should be about 5% of the zinc, in nitric acid. Add 10 c.c. of sulphuric acid; evaporate to fumes; dilute and filter out and wash the lead sulphate. Dilute the solution to 500 c.c.; add 5 gm. of ammonium chloride; pass a slow stream of hydrogen sulphide for one hour and let stand for about five hours; filter, wash with hot water; dissolve in 10 c.c. of sulphuric acid and 50 c.c. of water; filter and wash. Dilute to 400 c.c.; precipitate with hydrogen sulphide as before. Weigh as cadmium sulphide or dissolve in hydrochloric acid, and titrate with potassium ferrocyanide.

8. Claims to be considered shall be in writing within thirty days of receipt of material at customer's mill, and the results of customer's test shall be given. The shipper shall be given one week from date of receipt of such claim to investigate his records, and then shall either agree to satisfy the claim or send a representative to the mill.

(*a*) *Analysis by car lots.*—No claims shall be considered unless the minimum samples as specified for the grade in question can be shown to such representative.

(*b*) *Physical defects of individual pieces.*—No claims shall be considered unless the spelter in question, unused, can be shown to such representative.

9. Where the spelter satisfies the chemical and physical requirements of these specifications, it shall not be condemned for defects of alloys in which it is used or for defects in the coating of galvanized products.

10. The maker's representative shall inspect all pieces where physical defects are claimed. If agreement is not reached, the question of fact shall be submitted to a mutually agreeable umpire, whose decision shall be final. On a question of metal contents an adequate sample shall be drawn by the representatives of both parties; the sample shall be prepared from the slabs so selected as described above. The sample shall be mixed and separated into three parts, each of which shall be placed in a sealed package, one for each party and one for the umpire if necessary. Each party shall make an analysis, and if the results do not establish or dismiss the claim to the satisfaction of both parties, the third sample shall be submitted to a mutually agreeable umpire, who shall determine the question of quality and whose determination shall be final.

11. The expenses of the maker's representative and of the umpire shall be paid by the loser or divided in proportion to concession made in case of compromise. In case of rejection being established, damages shall be limited to the payment of freight both ways by the maker for substitution of an equivalent weight of spelter meeting these specifications.

CHEMISTRY is the science which investigates the composition of substances, and studies changes of composition and reactions of substances upon each other. As an applied science, it deals chiefly with the working over of crude natural material, and its conversion into more valuable and more useful substances.

Operating Costs and Mine Management

By Charles Janin

The difficulty of making comparisons between costs of different mines is strikingly apparent to anyone who tries to tabulate the figures found in company reports. The operating costs at a mine are governed, among other things, by the size and character of the vein, hardness of the country rock, depth of mining, amount of water to be handled, cost and efficiency of labor, the metallurgical treatment, magnitude of operation, and the cost of power. A knowledge of these conditions is important in making comparisons of operating costs. It is also necessary to consider the situation of the mine, the transportation facilities, the cost and difficulty of obtaining labor, and the cost of supplies. Mines situated in different localities may be operated under closely similar conditions as regards wages, power, size and character of orebodies, and metallurgical treatment, and comparison of operating costs between such mines will be both interesting and instructive. Comparisons cannot, however, be profitably made between mines unless they are operating under somewhat similar conditions. Comparisons between different mines on the Mother Lode or between different mines in the Grass Valley district of California are profitable, but direct comparison between costs at Mother Lode and Grass Valley mines is valueless because of the widely different conditions and methods employed.

The matter of bookkeeping is often a serious obstacle in comparisons. The not infrequent manipulation of the books, and the preparation of cost sheets that do not represent the actual conditions, but place to capital expenditure, or omit altogether, charges that should rightly go to operating cost, while reflecting apparent glory upon the management adopting such a policy, give but little information of real value and apparently reduce the actual operating cost by the amount so juggled. A wide difference exists between the cost system kept at those mines where a refinement of bookkeeping leads to itemizing the number of candles, and cost per foot of drift run, or the pounds of different sized nails used in building repairs, and those where the management has only a hazy idea of the number of tons mined and milled, or where the superintendent generally 'guesses' at the cost per ton, or takes such figures as he may have over a short period, ignoring the cost of supplies on hand and used, and overlooking other vital expenditures. The operating cost per ton assumed under the latter conditions is generally a low one, in instances coming under my observation, from 75c. to $2 per ton less than the more nearly correct operating cost, as afterward figured from a careful accounting of the total expenditures for supplies, payroll, and contingent expense over as long a period.

Again, there are wide discrepancies in the estimation of the tonnage treated. A car is generally used as a unit, sometimes arbitrarily taken as a ton or a ton and a half measure, and often, if the ore is weighed, no allowance made for excess moisture. The actual amount of ore may be anywhere from 10 to 20% less than the unit taken. At one mine where a system for weighing the ore was put in it was found that the actual tonnage treated was one-third less than what had previously been thought. An estimation from the stopes is not possible when the mine plans are not kept up to date and when the examining engineer has to rely on verbal information as to the extent of ground stoped.

Some fairly well conducted mines do not keep tabulated cost data, the management looking upon such accounting as an unnecessary expense, since it requires additional assistance. The old-time superintendent was not one whose education was along lines leading him to appreciate the desirability of keeping such data, and often though possessed of good underground experience and sufficient ability to carry out construction and operative work, he did not have a thorough knowledge of many of the details of the mining business. Neither had he any accurate idea of the real cost as compared with the apparent cost of operations. Where cost data are carefully and intelligently kept, it generally results in increased efficiency and a lowering of operating costs. Points that would otherwise be overlooked are brought to light, such as a too heavy or suddenly increased expenditure in any department so the steps may be taken to correct the abuse.

Low costs do not always mean large profits. Perhaps capital expenditure for new equipment results in reducing the actual operating cost, while the final accounting and amortization of the new plant would show a profit considerably lower than if the work had continued under the old methods. Nearly every engineer when called in consultation over the future of a mining project desires to make a record in lowering the costs of his predecessor. Often this ambition results in irreparable damage to the mine. For instance, economy in timbering has resulted in disastrous caves. Shutting off development and devoting all attention to extraction of ore already developed, while temporarily pleasing to stockholders and apparently increasing profits, brings an ultimate crash; generally after the engineer has accepted work elsewhere. He afterward points to the record of low working costs that no one following him has been able to reach; thus impressing those who do not know the true situation. In other words, the question of total profit is not always as seriously considered by the ephemeral manager or consulting engineer as is desirable. Too often he loses sight of the ultimate welfare of the mine in the effort to establish a record.

Again, low mining and milling costs per ton may mean a real loss in operations, and efforts in this direction occasionally result in good mines being run at a loss. Sometimes tonnage is attained by mining unnecessary waste, resulting in an apparent reduction in working costs per ton, thus reflecting credit to the management, but resulting in actual ultimate loss to the company. Mining of a smaller tonnage at a greater operating cost per ton could advantageously be made in such cases with an increased profit. A change in the method of ore treatment may sometimes be of great benefit. The great strides in recent years in cyaniding silver ores, and in slime treatment, have, with a reduction of working costs and an increase in percentage of recovery, made possible the economic treatment of ore formerly considered of little value. It would seem that any great reduction in working costs at mines to be made in the future, will be in the metallurgical end through improved methods and more efficient management, though appreciable reductions in cost may be made in every department of a mine that has not now the benefit of an experienced staff.

A field for the reduction of milling costs lies in increasing the efficiency of the stamp duty. It must be said that mill-men generally seem to be behind some of the more progressive men on the Rand, and, aside from their reluctance to try new methods, it is not easy to understand why more efforts have not been made to increase the mill capacity on lines similar to those evolved in South Africa. By using a heavier stamp battery for coarse crushing and following with tube-mills or other regrinding apparatus, it seems possible with most of the ores amenable to the simple method of gold mining, to increase the stamp capacity from the present 3 to 5 tons to two to three times that amount.

A familiar saying of one successful mine operator of early days was 'to the devil with a mine that won't stand bad management,' but there are a number of mines that are in the ranks of the dividend payers today where the balance between success and failure depends upon such a narrow margin that with careless or less experienced management they could not be profitably operated. To illustrate the difference in management, a case may be mentioned where the management of a well known Nevada mine, by devising a different method of ore development and extraction, reduced the operating cost of mining by over $2 per ton. The manager is to be highly commended on his success, which was not only due to a better method of handling the ore, but to a considerable increase in labor efficiency and to the building up of a strong esprit de corps in the staff. In some mines a bonus is offered the foremen in ratio to decreased cost; this has produced wonderful results, and this is a method that could be adopted in many mines.

Low working costs result only from close management, close figuring, and constant supervision by a capable, energetic man familiar with the details of operation. At one mine an average of 80 men were working while operating only 10 stamps. The ore was hard quartz and the vein narrow. Hand-drills were used exclusively. After thoroughly familiarizing himself with the conditions, the new manager put in a compressor, increased the mill to 20 stamps, weeded out the least efficient labor, and put good foremen in charge. He found that a force of 60 men, under these conditions, was sufficient, and work progressed more satisfactorily than before. Under the first manager the number of trammers and shovelers had gradually increased to 12. Under the new regime it was found that 6 men could do this work. The policy of the new manager in shutting off all useless expense and inefficient labor changed the mine from a close or dubious into a profitable enterprise. It is surprising how the number of men on the payroll will gradually increase unless carefully watched. A few extra men are needed perhaps for this or that new work, and the foreman, unless he is on a bonus arrangement, will generally keep them on after the work is finished.

The greatest cost in mining is that of labor, which runs over 50% of the total mining and development cost in all mines on which I have accurate data. The cost of explosives is also important; experiments recently made in one mine demonstrated that by a more careful selection, careful tamping of holes, and the use of considerably less powder, a saving of 20% was made in the powder bill. Miners are nearly always careless and extravagant in the use of powder and candles, and a careful supervision of these supplies will often work a considerable saving.

The overhead cost at mines of small output is sometimes a considerable item per ton treated. Especially will this be noted at mines where, as above mentioned, development has not kept pace with extraction. At such places present operating costs cannot be properly compared with those mines that have not suffered from 'engineering' ambition, or lack of proper development, until the former have again been put in proper shape. At other mines the management cost is higher than necessary, for the reason that the numerical strength of the staff and salaries paid would be sufficient for a concern of several times the size, and are far in excess of what the conditions warrant. Mention must be made here of a small mine in Mexico, where, if it had been in charge of an experienced superintendent instead of being inflicted with a 'staff of incompetents,' a different tale would have been told the stockholders.

An example where increased operating cost, over that of the former manager, was not only legitimate but necessary, may be mentioned. This was a mine being operated through a shaft about 400 ft. deep. When the first manager had blocked out a considerable quantity of ore, this work being charged to development, he then stopped all work in the shaft and at the face of the drifts, and devoted attention to extraction and milling of ore. The working cost while mining and milling was $2.25 per ton. With the advent of a new manager, who faced the necessity of rapidly developing more ore, costs advanced to $2.75 per ton, and later to $3.25. Soon after this the new manager received a stop order from headquarters and explanations were in order. The first manager had established a 'record' that could not be maintained simply because he did not do all the work incident to mining the ore over the period for which figures were quoted. Another example is that of a California mine where the total operating costs for a considerable period, with economical management, were slightly under $4 per ton. The mine changed hands and the costs increased over 70%. The mine is no longer a profitable undertaking.

Block-Caving and Sub-Stoping at Crystal Falls

By Fred C. Roberts

*The systems of mining used at the Tobin mine, Crystal Falls, Michigan, were developed after trial of several methods. Underhand stoping was tried, but soon discontinued on account of the continual falling of the ground from the back of the stope. Back-stoping was next tried, but the danger from falling ground was still too great. Sub-stoping was the third method used, and in some parts of the mine proved satisfactory. It is still used to some extent where the orebody is too narrow or too firm to be mined by the block-caving system. Block-caving was the next method used, and proved so well adapted to the conditions and physical characteristics of the ore that it has been adopted as the principal means of mining.

The levels at the Tobin are 125 ft. from floor to floor, and the main haulage drift follows closely the hanging wall. In the block to be mined by caving, parallel cross-cuts, 24 ft. from centre to centre, are driven from the main drift, as nearly at right angles as may be, to the foot wall, and are connected at the foot wall side by a small drift for ventilating purposes. Throughout the length of these cross-cuts, chute-raises are put up alternately on the right and left sides at intervals of 15 ft., to the sub-level 25 ft. above. The sub-level is opened 25 ft. above the back of the main level. A drift is driven, parallel with and about 15 ft. from the hanging wall, the entire length of the block to be mined. Cross-cuts are driven to the foot-wall from this sub-level drift directly above the cross-cuts on the main level. Opposite each cross-cut on the sub-level a raise inclined about 45° is put up from the sub-drift to the hanging wall, the object being to leave an additional thickness of back above the main haulage-drift. The cross-cuts on the sub-level are connected every 15 ft. by drifts over the line of chutes, leaving small pillars of about 10 by 16 ft. It is sometimes necessary to cross-cut these small pillars again, depending upon the nature of the ground. A drift is also driven along the foot-wall connecting all the cross-cuts.

After the pillars have been reduced to a suitable size, they are drilled with a sufficient number of holes so that they may be all blasted at once, the pillars farthest from the man-way being drilled first. Holes are also drilled around the tops of the chute-raises and blasted, making the raises funnel-shaped at the top. At the ends of the block to be caved, it is necessary to weaken the ground so that it will cave square with the pillar. Raises are put up from the end cross-cuts at varying intervals, depending on the nature of the ground. These raises are connected by two cross-cuts 25 and 50 ft., respectively, above the sub-level. After all the necessary raising, driving, and cross-cutting have been completed, the holes in the pillars of the sub-level are all blasted at once, undercutting the entire block, which settles down on the back of the level below. The ends of the block not being entirely cut off from the pillar, the ore does not drop down in one solid block, but breaks in settling and comes down in such shape that it can be handled through the funnel-shaped chute-raises with only occasional blasting of masses that lodge in the chutes. The caved ore is drawn uniformly throughout the level, so that it will settle down evenly, and this keeps the caved rock from the old level above from getting mixed into the ore.

Sub-stoping is used where caving is not practical; at the narrow ends of the orebody, and in pockets and smaller deposits that are sometimes found separated from the main body. Conditions vary so in these cases that they have to be met in different ways. The nature of the ground and dimensions of the orebody have to be taken into consideration in each case, and the method of mining

---

*Abstract from paper presented to Lake Superior Mining Institute.

adapted to it. The usual method is to drive a drift on the main level the entire length of the orebody in question, and determine the width of the same by cross-cuts. Chute-raises are put up at intervals of about 15 ft. From a raise, at the end of the ore nearest the shaft, a sub-level is opened 15 ft. above the main level. This sub-level consists of a drift the length of the ore and connected at the far end with a raise from the main level. Second, third, and fourth 'subs' are opened in a similar manner above the first, 20 ft. being the usual distance from the back of one sub-level to the floor of the next above. The raise at the far end of the ore is carried through to the upper sub. All preliminary development work being completed, stoping is begun at the far end of the ore on the lower sub-level. Upper and underhand holes are drilled and blasted around the raise which connects all the subs at the far end. The ore thus broken falls into the chute at the bottom of the raise. This is repeated until the lower sub is drawn back 12 or 15 ft., when the miners on the second sub begin stoping in a similar manner to that done on the first sub. The second sub having been drawn back to a safe distance, the third sub-stope is begun. In this way each gang of miners is always working under solid ground and far enough back to escape falling ground from the stopes above.

The width of stope that can be carried this way depends upon the nature of the ground. In the Dunn and Great Western mines where the ground was exceptionally firm, with a strong capping above, stopes were worked out 80 ft. wide. The first stope was carried 30 ft. wide through the middle of the ore, beginning at the far end and drawing back. Benches were then cut at each sub-level the entire length of the ore pillar on each side of the stope. These benches were cut into the pillar far enough to protect the men from falling ground from the others working above. Beginnning at the far end and drawing back, these benches were stoped out by upper and underhand holes, the broken ore falling into the open stope. The process was repeated to remove the remaining ore in the pillars.

Coal Trade of the Pacific Coast

The fuel requirements of the Pacific Coast and the methods of meeting them will be discussed in the report on the production of coal in 1910, by E. W. Parker, of the U. S. Geological Survey, now in preparation.

The present consumption of coal on the Pacific Coast, according to Mr. Parker, is not large, and the successful operation of any coal mines in Alaska will depend on naming prices attractive to the development of manufacturing industries. For railroad and manufacturing purposes, the consumption of oil, particularly in California, largely exceeds that of coal—in fact, for railroad use oil is practically the only fuel. The principal domestic fuels are wood, and gas made from oil. Recently oil itself has assumed importance as a domestic fuel. About 15,000,000 bbl. of California oil were consumed by locomotives in 1909, as against a little over 18,000,000 in 1910. The total consumption of fuel oil was probably between 35,000,000 and 40,000,000 bbl. in 1909, and between 40,000,000 and 50,000,000 in 1910. The probability is that the consumption of fuel oil displaced about 10,000,000 tons of coal on the Pacific Coast in 1909 and between 11,000,000 and 12,000,000 tons in 1910. The per capita consumption of coal in California, Oregon, and Washington averages not much over 1 ton, while the average consumption in the United States as a whole is about 5¼ tons for each inhabitant.

The principal source of coal supply for the Pacific Coast is the State of Washington, the output of both California and Oregon being at present small. In 1909 the total production of coal in Washington was 3,602,263 short tons. California produced 45,000 tons and Oregon 87,276 tons. In 1910 the production of coal on the Pacific Coast was 3,903,983 short tons in Washington, 62,707 tons in Oregon, and 11,164 tons in California. The imports of bituminous coal amounted to 752,046 tons, and of anthracite to 9116 tons. The exports of coal from Seattle were 26,883 tons in 1909 and 23,771 tons in 1910. The total consumption of coal on the Pacific Coast from various sources in 1909 was 4,576,052 short tons and in 1910 4,812,389 tons. The imports of coke to Pacific Coast ports (exclusive of Hawaii), as reported by the Bureau of Statistics of the Department of Commerce and Labor, were 111,676 short tons in 1909 and 114,061 tons in 1910.

Including 761 short tons of coal sent from Puget Sound to Bering Sea, the total quantity of coal shipped into Alaska in 1910 was 98,420 short tons, of which 8178 tons went from British Columbia, and 15,877 tons from Washington. The production within the Territory was reported at 1000 tons, or about 1% of the total consumption.

Mining in New Zealand

The Wellington committee of the Waihi G. M. Co. held a meeting early in July, when a report was presented stating that replies to the circular which had been sent out disclosed the existence of a strong feeling against the present management. Owing to a regrettable misconception of the purport of the motion to remove the registered office of the company to New Zealand, in order to save New Zealand shareholders from paying double income tax, the committee did not get the support in England which its efforts should have obtained. However, A. E. G. Rhodes, a New Zealander, had been appointed an extra member of the board. Advices received at Waihi indicate that J. W. Walker is still seeking capital in London for the exploitation of mining leases, totaling 2000 acres, and reaching from the Waihi Reefs Con. property to the seacoast. Should his efforts be attended with success, a shaft will be sunk to a depth of 800 ft. in mineralized country, and prospecting drifts undertaken across the trend of the Waihi reef system.

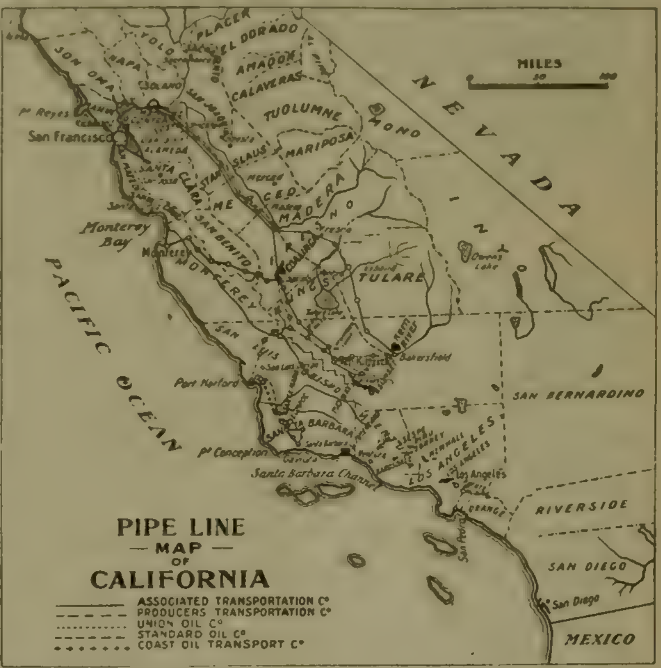
Steps are being taken by mining men now in London, and who are interested in the Waihi Beach mine, to raise capital for the flotation of a new company to thoroughly develop the claim, says the *Otago Witness*. Should the money be raised, it is intended to sink a main shaft farther inland, where operations can be conducted from a more central point. At present the property is under option for six months, commencing from May 30.

During June the Talisman Con. G. M. Co., whose property comprises 565 acres near Karangahake, crushed and treated 4580 tons of ore with a return of bullion valued at £19,020. Compared with the return for the corresponding period of last year, when 4090 tons yielded £18,372 5s. 5d., the past month's crushing represents an increase of £648. Costs for the past month totaled 34s. 6d. per ton, made up as follows: Mine development, 8s. 3d.; mining, 12s.; milling, 12s. 5d.; general expenses, 13s. 10d. The total value of bullion won from the mine to date is £1,525,622. The directors of the Taranaki Petroleum Co., at Moturoa (N. Z.), recently purchased 3500 ft. of 2-in. casing, and complete pumping-plant, from the Standard Oil Co. This casing will be placed in the well, and the oil allowed to flow. It has been flowing for some time between the casings in fairly large quantities, and in about a week it will be seen what the well is capable of producing. Oil still flows satisfactorily at No. 2 well, the quantity being well up to the usual average. No. 3 is now drilled to a depth of 4015 ft. The original intention was to drill to 4000 ft. The directors are now taking steps to test the oil at this depth. Many years ago oil was tapped in the Kotuku district, but absence of modern appliances and lack of expert knowledge have hitherto retarded development. The Consolidated company, of Reefton, however, is pushing ahead with boring operations. The latter operations contemplated will induce a large influx of mining men, and to provide for their housing, G. H. M. McClure (commissioner of crown lands) has gone to Kotuku to plan out the future town of Kotuku.—*Australian Mining Standard.*

Pumping California Petroleum

By C. P. Bowie.

The total length of oil pipe-lines in California at the present time is about 1600 miles. Of this amount 1250 miles leads from the San Joaquin Valley fields to the sea-coast and is owned and operated by four companies: (1) the Associated Pipe Line Co., which operates 262 miles of 8-in. line from the Sunset and Kern River fields, Kern county, to tidewater at San Francisco bay; (2) the Standard Oil Co., which has an 8-in. line 280 miles long from near Moron, Kern county, by way of Bakersfield, to Point Richmond in Contra Costa county, which line is joined in Fresno county by an 8-in. branch leading from the Coalinga fields; (3) the Producers' Transportation Co., whose 8-in. line extends from the Kern River fields, the Sunset fields, and the Coalinga fields to a junction station near Dudley, Kings county, and thence to the sea-coast at Port Harford, San Luis Obispo county, a distance in all of 200 miles; (4) the Associated Transportation Co., which has a 6-in. line 108 miles long from Coalinga to tidewater at Monterey, in Monterey county. The remaining 350 miles is made up of short lines in the southern part of the State leading from the coast fields to the ocean. Of these lines the Associated Transportation Co. operates one 8-in. line 35 miles long, and one 4-in. line 30 miles long from the Santa Maria fields to Gaviota in Santa Barbara county. The Coast Oil & Transportation Co. operates an 8-in. line 30 miles long from the same fields to Port Harford; the Standard Oil Co. operates an 8-in. line 28 miles long from near Orcutt, Santa Barbara county, to Port Harford, and a 3-in. line 45 miles long from the Torry Canyon fields in Los Angeles county to the city of Ventura; and the Union Oil Co., has both a 6-in. line 30 miles long, and an 8-in. line 50 miles long from the Santa Maria fields to Port Harford; a 4-in. line 45 miles long from Torry Canyon to Ventura, an 8-in. line 30 miles long, and a 6-in. line 25 miles long, from the Whittier and Salt Lake fields to San Pedro in Los Angeles county.



PIPE LINE
— MAP —
OF
CALIFORNIA

The base of the California oils is asphaltum. The gravity varies from 14 to 35°B., and the depth of the wells from 200 to 4000 ft.; the lighter oil being found usually in the deeper wells. In the Kern River fields, which was the first of the inland fields to be extensively developed, the producing sands were found at a distance varying from a few feet in depth to 1300 ft., and fully 80% of the oil was of a heavier gravity than 15° B. The difficulties in moving this viscous material through pipe-lines, especially in cold weather, has given rise to two distinct systems of pumping, known locally as the 'Rifled Process' and the 'Hot Oil Process'.

THE RIFLED PROCESS

The 'rifled process' was invented by J. D. Isaacs, consulting engineer of the Harriman railroads, and Buckner Speed, a professor in the University of California. It has been successfully used for the past three years by the Associated Pipe Line Co. between Bakersfield and Port Costa, Contra Costa county, this being the only rifled line operated in the State. The process consists in pumping cold oil of from 13 to 14° B., together with about 10% by volume of water, through a pipe which is corrugated spirally or 'rifled'. These rifles are put into the pipe in the making by running each joint with a twisting motion through a set of rolls, consisting essentially of wheels about one-fourth of an inch wide, which push the indentations into the pipe from the outside. The rifles make one complete revolution of the circumference in ten feet of length of pipe and give to the interior of the pipe much the same appearance as the barrel of a gun.

In operation, water is forced along the inner periphery of the pipe through an injection nozzle surrounding the pump discharge and at a distance of about ten feet from the pump. The pipe being already filled with oil, the water in this way is forced between the core of oil and the pipe itself. As the mass moves forward the rifles give to it a whirling motion. The water's greater specific gravity and this centrifugal motion form a water film between the pipe and the oil, thus keeping the oil from coming in contact with the pipe and consequently greatly reducing the frictional resistance.

Experience has shown that the following conditions are essential to the successful operation of a rifled system: (1) The oil must be very viscous—of a gravity not lighter than 15° B. An oil of higher gravity will form an emulsion with the water and produce a mixture which is very difficult to pump. (2) The oil must not be too warm. Heating an oil raises its gravity and increases its tendency to emulsify with the water. Best pumping results will usually be obtained when the oil has a temperature of from 65 to 85° F. (3) The velocity of the mass must be at least 3.5 ft. per second and should be greater if possible. (4) Sharp bends, rough places, etc., in the line which tend to break the water envelopment must be avoided.

The line now operated under this system is 285 miles in length. A steel pipe is used, 8 in. in diameter, each joint being tested in the shop to withstand a working pressure of 1200 lb. per square inch. Pumping stations average 24 miles apart, giving an available fall in pressure per mile, assuming 800 lb. working pressure on the pumps, of from 32 to 35 lb. At each pump station the oil is run into a tank and allowed to settle for from 24 to 48 hours or longer. The water, being heavier than the oil, will gradually drain to the bottom of the tank, where it can be drawn off. The process of settling is, however, much slower than might be expected, and no attempt is made to entirely separate the mixture before re-pumping. Although the oil is thus settled eleven times during the process of pumping 285 miles, it reaches the terminal station holding in mechanical mixture about 25% water. The greater portion of this water would probably leave the oil if the mass were allowed to remain undisturbed a sufficient length of time. However, to hasten the settling and render it more complete, the mass is pumped through a heating tower, or tank, 15 to 25 ft. in diameter and 40 ft. high, the first 12 ft. of which tank contains water at

212° F., kept boiling by means of steam-coils. The incoming oil is passed direct from the field line into this tank, which it enters through a pipe lying on the inside bottom of the tank in the form of a Maltese cross. In the upper circumference of this pipe slits are cut about ¼ in. wide and from 1 to 1½ in. long. These slits distribute the mixture into the boiling water in a series of ribbons. The sudden heating causes the oil to lose the greater portion of its moisture, so that it may be drawn off at the top of the tower containing not over 2 to 5% of water. From the heating tower the oil goes into a settling tank, where it is allowed to stand for several days. From this tank it is finally drawn off to cars and ships through a swing pipe operated to draw always from the top of the oil. Any water which settles in this tank is carried away through a bleeder in the bottom.

Commerce demands a fuel oil containing not more than one to two per cent of moisture. To make sure that this proportion is not exceeded, samples are taken daily from various depths in each settling tank as well as from all cars and vessels as they are loaded. It will usualy be the case that practically all the oil is drawn from a settling tank before the specified percentage is exceeded. There is, however, always a certain amount of residue left in each settling tank which contains water in excess of requirements. This residue is either passed back through the heating tower or placed in a similar but somewhat smaller tower where superheated air is pumped through it until the excess of moisture is evaporated.

HOT-OIL PROCESS

All other pipe-lines in California are operated under the so-called 'Hot-Oil Process'. This system consists in pumping the oil dry, that is, without the addition of water, and of passing it at each station, before it reaches the main-line pumps, through a heater where the temperature is raised from normal to 130 or 150° F., depending on the temperature of the atmosphere. The heater consists usually of a drum 5 ft. in diameter by 21 long, constructed much on the principle of a water-tube boiler. In this the oil, while passing through, is heated by means of exhaust steam.

Experience in pumping oil by this process indicates that the essential features to successful operation with California oils are: (1) An oil lighter in gravity than 16° B.; (2) A temperature at all times of 100° or greater; (3) A velocity of at least 3.6 ft. per second.

An oil of somewhat less gravity than 16° B. can be pumped, but its movement will be sluggish because of its high factor of viscosity. Raising the temperature of an oil will increase its fluidity; in general, any California oil between 16 and 20° B. must be raised to a temperature of at least 100° F. before the viscosity factor is sufficiently reduced to insure a free movement of the molecules of the oil one upon the other.

Under ordinary conditions, as when practically all of a pipe-line is buried in the ground for its total length and the pipe is running full under a constant velocity, the fall in temperature of heated oil between the initial temperature and normal is almost directly proportional to the distance traversed. When the distance between pumps is too great to admit of incoming oil having a temperature of 100° F., intermediate heating-stations are constructed. The heaters are placed in a bypass from the main line and consist of a two-compartment brick flue about 250 ft. long. In each compartment is placed a number of rows of pipe, about four inches in diameter, in such a manner that the oil, which enters the flue at one end, travels the full 250 ft. by the pipes in one compartment and returns a similar distance to the same end at which it enters by the pipes in the other compartment. The heater is fired either at the end or in the middle, and the air in the flues is kept at a temperature of from 400 to 900° F. With such an arrangement it is possible to raise the temperature of oil having a velocity of 2.5 ft. per second 40 to 60° Fahrenheit.

Pumping-stations for this system are usually so spaced as to give an available fall in head per mile of 60 lb. per square inch with 800 lb. working pressure at the pumps, or in level country they would be about 13.3 miles apart. The pipe used is black line pipe tested to withstand a working pressure of 1200 lb. per square inch.

The Davis, Oklahoma, Zincfield

By L. C. Snider

In the heart of the Arbuckle mountains, 7 miles southwest of Davis, Oklahoma, is a zincfield which has recently shown promise of development. The productive horizon is a dolomitic member in the lower part of the Arbuckle limestone. The dolomite outcrops from northwest to southeast along the northeast side of two large granite-porphyry hills, known as East and West Timbered Hills. The belt has a length of 15 miles and an average width of less than ½ mile. The porphyry and dolomite are separated by the Reagan sandstone, of Middle Cambrian age, and the lowest portion of the Arbuckle limestone, which is a dense, thin-bedded, blue-gray limestone. The limestone above the dolomite is similar to that below, except that the layers are much thicker. Locally, at least, there is an intraformational limestone conglomerate at the top of the dolomite. The limestones and dolomite dip steeply to the northeast away from the granite porphyry. The average dip is between 40° and 50°, but there is much variation due to minor folding and to faulting. Many small faults almost perpendicular to the strike cross the outcrop of the dolomite. The lateral displacement due to these faults varies from a few feet to 20 rods. In every case the northernmost block is displaced to the east. All the rocks are much broken by jointing, but this is especially true of the dolomite. A sharp blow of the hammer breaks a large block into small, angular fragments, few of which are over one inch in any dimension. The concentration of the zinc in the dolomite is probably due to this broken condition, the small seams forming channels for the passage of circulating waters carrying zinc in solution and at the same time affording small cavities for the deposition of the ore.

It is claimed by the prospectors and others interested, that all the dolomite area contains rich ore, but from the present development this is only proved in a limited portion of the belt, lying in sections 17, 18, and 21, in T. 1 S., R. 1 E. Here the zinc ore occurs as the carbonate from the surface to a depth of 5 to 8 ft. Below this level the zinc is in the form of sulphide or zincblende. The carbonate contains large proportions of dolomite. The blende is usually finely disseminated, but in some cases seems to have largely replaced the country rock so that the blende makes up the larger portion of some of the strata. The two most important mines that have been opened show two layers of the blende-bearing rock, each 3 to 4 ft. thick, separated by a layer of 'dead rock' 5 to 6 ft. thick, carrying only thin seams of blende. A well being drilled on one of the properties is said to have shown the rich ore to a depth of 30 ft. and to have penetrated a similar body at 125 ft. below the surface.

The samples collected so far show the following results:* Four samples consisting of chips from surface blocks in different parts of the field show, respectively, trace, 0.17, 0.77, and 1.32% zinc; samples of carbonate from near the surface and from shallow prospects in different localities show, respectively, 0.55, 0.45, 0.77, and 5.4%. A sample composed of chips of a large number of blocks in a pile of blende ore selected for milling shows 25.46%; a sample of blende from one of the deeper prospects shows 8.88%; a sample from all parts of one of the most widely advertised mines or prospects shows 7.29%. The concentrate from the only mill which has been built shows 45.96%. The mill was not run long enough to get the crushing machinery and tables properly adjusted, so that the showing of the concentrate is probably not so good as can be obtained. Much higher values than those shown by these analyses are reported by others, and for that reason it is judged best not to give the exact location of the samples until a larger number can be collected and analyzed.

---

*Analyses by Frank Buttram, chemist, Oklahoma Geological Survey.

Other metals occur in small quantities with the zinc. An interesting feature is a narrow belt of iron ore (hematite) seldom over one rod in width, which lies near the middle of the dolomite member throughout the length of its outcrop. Bowlders of hematite, in part altered to limonite, are strewn thickly along the surface of this belt. Some of them are as much as 10 ft. in diameter. In only a few cases does the iron ore extend as much as 10 ft. beneath the surface. The richest portion of the zinc ore so far seems to be in close proximity to this iron bearing horizon. The cause of this segregation of the iron ore into so narrow a belt is problematic, but it is entirely possible that it is due to a small fault parallel to the strike of the rocks. Such a fault would be almost impossible to trace in the dolomite unless the belt of ore itself be taken as evidence of its existence. The localization of the ore took place before the formation of the small faults perpendicular to the strike previously mentioned, since the iron-ore belt is offset by them.

Pyrite and marcasite are practically absent from the zincblende in the body of ore near the surface. The cuttings from the deep body found in the well previously mentioned show some pyrite, but it is apparently in small quantity. Lead occurs in small quantity near the surface as the sulphide and as the carbonate. Copper stains are often present, and some pieces of malachite and azurite have been discovered in different parts of the field. So far no large body of copper ore is known to have been found, although there are rumors to the effect that such bodies exist.

The principal development so far consists in small openings or prospects. One company has a mill with four concentrating-tables. The mill was run less than one day before the water-supply was exhausted, consequently little can be said of the milling properties of the ore except that fine grinding is necessary to insure complete separation. A well is being drilled at this mill in the hope of securing a permanent water-supply. Three other companies have boilers on the ground and mills ordered. One of these companies has a core-drill outfit ordered and plans to prospect thoroughly for deep-seated ore. Several carloads of carbonate ore have been shipped from the field. This is reported to have paid fairly well. One or two carloads of sulphide ore has been shipped, but the results could not be learned.

Although there is undoubtedly considerable ore present in the field, there are several factors which combine to make the value of the field somewhat problematical and to render any prophecy along this line a matter of guesswork. Some of these factors are as follows:

1. The question as to the areal extent of the ore. While the prospectors admit that the richest ore is near the outcrop of iron ore which has been described, they claim that good ore is present practically to the edges of the dolomite outcrop. The samples so far collected from prospect pits near the edges of the dolomite, and analyzed in the Survey laboratories, do not bear out this claim, but the number of samples collected is too small to warrant a definite conclusion.

2. The depth to which ore occurs. The first body of ore does not exceed a depth of 40 ft. over most of the area which has been the most thoroughly investigated. The only investigation at a greater depth than 50 ft. is the well which has been mentioned. Some ore was found at about 125 ft., but as a churn-drill was used, neither the exact thickness nor percentage of zinc can be told with accuracy. Thorough prospecting with a core-drill is the only method of settling this question, and until this is done, any statement as to the probable value of the field must be founded on mere supposition.

3. The absence of pyrite is favorable to the production of concentrate low in iron, but, on the other hand, the extreme fineness of grain of much of the ore will render complete separation very difficult, and the concentrate will probably run high in lime.

4. The question of adequate water-supply is unsolved. The portion of the region which is being developed lies near the headwaters of a small creek, and there is not sufficient water through most of the year to supply the ore-concentrating mill already built. The limestone and dolomite are too badly fractured to form a reservoir for any water which might be impounded during the wet season. The problem may be solved by the deep wells which are proposed, but the high dip of the rocks, the small catchment areas, and the presence of numerous sink-holes renders it improbable that an adequate supply will be found at any reasonable depth. A possible solution is to pipe water from Honey creek near Turner's Falls. The distance is about 4 miles from the mines in section 18, and the mines are approximately 250 ft. above the creek. Water for the northern portion of the field can probably be secured from Colbert creek, about 2 miles below the stream from the mines.

5. The ore or concentrate must be hauled to Davis, a distance of 7 miles, over roads which at present are very bad. This, of course, is not prohibitive, but should be borne in mind in trying to arrive at any estimate as to the value of the field.

Silver and the Far East

Below are London's exports of bars of silver to the Far East, including India and China, together with corresponding influences affecting prices of silver, in pence:

	Av. price in pence.	London exports.	Influencing events.
1902	24 1/16	£ 7,565,305	Boxer war; silver falls.
1903	24¾	8,051,780	India buys heavily.
1904	26⅜	10,038,319	U. S. buys for Philippine coinage.
1905	27 13/16	8,643,405	Mexico stops free coinage; India buys more.
1906	30⅞	15,565,334	U. S. and India buy silver.
1907	30 3/16	12,752,230	India stops buying.
1908	24⅜	10,243,968	General depression.
1909	23 11/16	8,936,765	Big cotton crop.
1910	24⅝	8,700,000	Big wheat crop.

Crop conditions in India are so intimately associated with silver that a good yield soon reflects itself in better silver prices, if not in larger takings. India's great cotton crop in 1909 of 3,773,000 bales was an increase of 44% over the previous two-year average. The wheat crop of 1910, together with a good cotton yield, combined to restore the hope and confidence in the future of silver. But the natives have taken more gold, commerce has called for gold instead of silver, and the Government has not bought. This has left the speculative banks of Bombay to finance the silver movement. To what extent they have unloaded is uncertain, but if they still hold largely in the face of the new year's crop conditions, their prospect is not encouraging, and the prime hope of higher prices may yet lie in the revival of trade and industry in China and elsewhere.—*Boston News Bureau.*

STEAM-SHOVELS have been in use abroad for many years, but all modern developments along the line of power and size have emanated directly or indirectly from the United States. American shovels are now standard for heavy work, though a few heavy machines have been built recently in Germany. The first real 'steam-shovel' built in America was made by the Pound Mfg. Co. at Lockport, New York, in 1870. It was built largely of wood, mounted on wooden wheels, and controlled by one vertical engine. It was necessary to dismantle it in order to move it any distance.

Dredging at Dawson

Staff Correspondence

This season began with one of the latest and coldest springs on record. Consequently all mining work was delayed. The two dredges of the Canadian Klondike Mining Co., at Bear Creek, began work the latter part of April, and those of the Yukon Gold Co. a few days later. All dredges have since been running smoothly and doing well. The 16-cu. ft. boat of the Canadian Klondike M. Co. is working satisfactorily, and the owners are much pleased. No serious defects have developed, and the boat has been able to maintain its expected capacity. This company's 7-cu. ft. boat is also doing good work. These two dredges were designed and constructed by the Marion Steam Shovel Co. at Marion, Ohio. There is some likelihood of the Canadian company building another boat of the same size and design as the 16-cu. ft. boat. However, this has not been definitely settled.

The Yukon Gold Co. has under construction two new 7-cu. ft. Bucyrus dredges, with steel hulls, the first of their kind in the Klondike. One of these boats is to be placed on upper Bonanza creek, and the other on No. 7 Eldorado creek. It is expected that they will be finished early in September, and will be well tried out this year before going into winter quarters about November 1. This company also moved one of its boats from Lower Bonanza creek to a point six miles farther up the creek during last winter. It was dismantled last fall and hauled up the creek over snow roads during the winter and reassembled early this spring, getting to work in the latter part of May, since when it has been doing well. When the two new boats are completed the Yukon Gold Co. will have six 7-cu. ft. boats and three 5-cu. ft. boats in operation—nine in all; these boats dig an immense amount of gravel during each season. As these dredges work their way up the creek they will undoubtedly be in richer ground; consequently, each year should show an increase in their combined output. They are all well equipped and splendidly managed. The hydraulic work of this company has been going steadily ahead this season, plenty of water having been available. Several new properties have been opened which should materially add to the output of this part of the company's holdings.

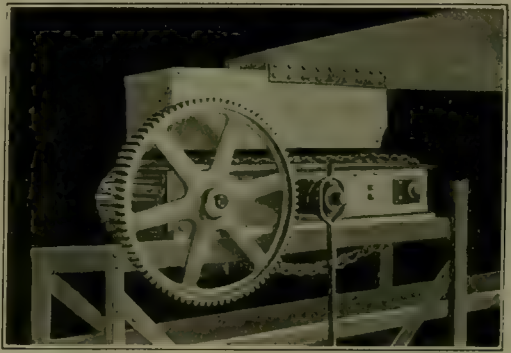
The Risdon dredge owned by the Gold Scoopers Co. of London, lately placed on the lower end of Walker Fork, Alaska, was dismantled last fall, and during the winter moved to the North Fork of Forty-Mile river, and reassembled this spring on a property known as Mosier Bar. This boat got to work early in June, and as the ground on which it is to operate is known to be exceptionally rich, there is no doubt that the boat will handsomely repay its owners for the difficulties they have experienced up to the present time. R. H. Milvain is resident manager for this company; Russel King, its president, remains in London. Mr. Milvain is also manager for the Walkers Fork Gold Dredging Co., whose property lies well up toward the headwaters of Walker Fork, a tributary of the Forty-Mile river, and is also in Alaska. The dredge belonging to this company is also a Risdon boat, and has been successfully at work since early in May. It is generally understood that some unexpectedly rich ground has been found of late, and it is to be hoped that this will continue. Generally, the clean-ups on this property are good, even for this country. The dredge operating at the lower end of the Forty-Mile river was sunk this spring during the high-water period and has not yet been raised.

The Northern Light & Power Co.'s plant at Coal Creek has been completed, and supplied power to the Yukon Gold Co. and the Canadian Klondike Mining Co. during the latter part of last season and the early part of this season. This company generates its power from steam, burning coal from its own mines, which are close to the plant, so that delivery to the furnaces virtually takes place at the mine's mouth. The plant has been shut down since about the first of July; it is probable, however, that it will be started up again about September 1. The hydroelectric power-plant of the Granville Mining & Power Co., situated on the North Fork of the Klondike river, began producing power this spring, and is at the present time supplying the Canadian Klondike Mining Co. with power for the two boats which they operate. This plant is capable of generating 10,000 hp. at present, and can be enlarged to twice this capacity at no great expense. It is expected that it will be necessary to increase its present capacity in the near future; this will be done as the occasion demands. The watercourse for the supply of the plant is ideally placed, running from its intake to the pressure-box over almost entirely level country. The entire bottom of the ditch is in gravel, so that no trouble need be feared from either leakage or the ordinary troubles of hillside waterways.

There is no new work under way in this section, though much talk of that contemplated; it is expected, however, that the Granville Mining & Power Co. will soon start work on a ditch that will carry water from the Klondike river up Hunker creek to a point opposite Dago hill, where it is understood it will be pumped by the company's power to an elevation sufficient to permit hydraulicking on this hill, which has an elevation of approximately 400 ft. above the Klondike river and 300 ft. above the ditch that will supply the pumps, necessitating a raise equal to at least 500 ft. for the purpose of hydraulicking. There have been some new finds made on tributaries of the Yukon river some hundred miles up-stream and south from Dawson, but nothing authentic has yet come in. On the whole, the district is in much the same condition as it was last year, though it is probable that this year's gold output will exceed that of last year, on account of the two new dredges now being erected by the Yukon Gold Co. and the addition of the 16-cu. ft. boat to the Canadian Klondike Mining Co. Account should also be taken of the richer gravel that Yukon dredges will undoubtedly secure as they advance farther up Bonanza creek.

Ore Feeder

At the Chino copper mine, Santa Rita, New Mexico, ore is drawn from coarse-ore bins upon a conveying belt which carries it to the rock-breaker. To meet the problem of gates and of steady feed the device figured below is used. The ore falls through an opening in the bottom of the bin, not as here represented through a chute, but directly upon a short length of steel conveyor which is mechanically operated. The gate itself is not closed, as when the conveyor is not moving the ore piles up on the belt and chokes. By changing the speed of the conveyor the amount drawn from each bin is regulated. The whole device is simple and effective. A similar arrangement was put in the Boston Consolidated mill when it was built, except that the short feeding-belt traveled at right angles to the main conveyor belt, instead of, as at Chino, parallel to it.



A cubic mile of average rock weighs 12,800,000,000 tons.

Discussion

Readers of the MINING AND SCIENTIFIC PRESS are invited to use this department for the discussion of technical and other matters pertaining to mining and metallurgy. The Editor welcomes the expression of views contrary to his own, believing that careful criticism is more valuable than casual compliment. Insertion of any contribution is determined by its probable interest to the readers of this journal.

The Economy of Dynamite

The Editor:

Sir—Having read 'Student's' letter in your issue of August 19, I wish to question his statements as to the energy developed by the explosion of one pound of dynamite.

H. Brunswig, in his 'Explosivestoffe' (page 61), gives the following results of calorimetric tests of various explosives. (I have changed the units from the metric to the foot pound system.)

Explosive.	Heat developed in lb. Cal. per lb.	Energy equivalent to heat in Col. 2, ft. lb.
Blasting gelatine (7% cotton)....	1640	2,240,000
Nitroglycerin	1580	2,210,000
75% dynamite	1290	1,797,000
Nitroglycerin pulver (40%) (gelatine dynamite?)	1290	1,797,000

I should be interested to know on what grounds your correspondent "assumes" the initial pressure of the explosion to be 120,000 lb. per square inch, and how he "calculates" the energy expended to be 724,150,000 ft.-lb. per pound of dynamite.

ANOTHER STUDENT.

Douglas, Arizona, August 22.

Pitch of Ore-Shoots

The Editor:

Sir—The inquiry of the 'Gentleman from Sonora' as to the direction of pitch or trend of ore-shoots in the plane of the vein, is one that interests all miners. I have heard numerous engineers and miners express opinions on this interesting and important subject, but as far as I am aware no 'rule' has, as yet, been discovered by which the pitch of an ore-shoot may be pre-determined. I have repeatedly heard mining men say, that: "standing on the outcrop of a vein and looking down the dip, the ore-shoot will trend to the right." This is correct—where it happens to occur that way, but there are a great many exceptions to this 'rule.' In some instances there are certain 'indications' which may be considered a guide, but I am not sure that these indications are always to be depended upon. Take a case where a slaty or schistose formation, having a north-south strike and an east dip, is cut by a vein having a northwest-southeast strike and a northeast dip—the angle in either case is unimportant. Along the walls of such a vein the laminations of the inclosing slate, or schist, where exposed in the mine workings, will usually appear as a series of striations, or grooves, of greater or less strength, and the ore-shoots, if there are any, will be likely to be found to pitch downward along the vein in the direction of the pitch of these grooves. These grooves or striations must not be confused with the striations produced by movement of the walls of the vein. These latter are of common occurrence, and some consider them a safe index of the direction of the pitch of the ore-shoots, but I have not found them to be dependable. In fact, it is no uncommon thing to see two or more sets of such striations running in different directions, on the same wall. They merely represent movement of the walls in different directions, at various times, due to change in the direction of stress in the rocks. The walls of a vein, whether conforming to the strike and dip of the enclosing rocks or not, are often sinuous in their course as well as in their dip, these planes (the walls), appearing as a series of wave-like undulations, forming a succession of rolls or troughs, of varying size. Generally these rolls have a trend or pitch downward along the vein. In such cases the ore-shoots are likely to follow the trend of these rolls. A number of interesting experiments can be made in studying the result of the intersection of the strike and dip of strata by veins, by placing a number of thin boards side by side to represent the strike and dip of the formation, and then sawing these at various angles to represent the vein cutting the formation in different directions of both strike and dip. The two examples above mentioned will, I believe, give the key to the situation in most cases, though there may be exceptions. The trend or pitch of ore-shoots along a vein is due no doubt to physical conditions, and the direction of this trend can be determined with reasonable certainty wherever the true nature of these physical conditions can be ascertained.

WILLIAM H. STORMS.

Berkeley, California, August 7.

Mining and Speculation

The Editor:

Sir—During the past four or five years that I have been a reader of the *Press* I have often noticed in its columns the statement, that mining is a speculation; and being a man of limited ability, I was swayed by this talk so I bought myself an alfalfa ranch. This accounts for my being in arrears with my subscription. I would like to have it made plain that mining is not a speculation but a business that must be thoroughly understood the same as any other business in order to be a success. I contend that the surface indications of a new mining property are like the preface of a book; if we were only smart enough to read them correctly.

Reverting again to the farm, I will say to the editor when you are tired, weary, and long to be away for a little rest and recreation, come to the Silver Oak's Farm, six miles northwest from Modesto, and enjoy the exhilarating rural breeze of new-mown hay, have spring chicken for breakfast, help yourself to all kinds of fruit, and smoke a corn-cob pipe to your heart's content. If we are not at home when you get here, the latch-string is on the outside of the front door just above the cat hole. Walk in, introduce yourself to the family, and be at home till I come to talk mines with you. Once a miner always one. I shall keep the ranch, but continue mining.

AN OLD MINER.

Modesto, August 22.

[Thanks for the invitation. We will come at the first opportunity. We agree that mining is not a speculation, except in the sense that any business is speculative, to one who goes at it with knowledge and determination. Our preachments have been aimed rather at those who have neither special knowledge nor persistence. To such persons mining is highly speculative, and they have no right to blame the industry if they lose money mining.—EDITOR.]

TEXAS IRON ORE is expected soon to be available, especially for Eastern markets. Transportation facilities are now being provided between the orefields in Morris, Cass, and Gregg counties and the shipping port of Port Bolivar on deep water. From Port Bolivar the ore will be transported by vessel around Key West to Philadelphia. Shipping from these mines may be inaugurated soon after October 1. According to the *Iron Trade Review*, prospecting and development have disclosed the presence of a large body of hematite in Texas. This ore runs about 48% iron in the natural state, about 0.12 in phosphorus, 12 in silica, and from 2 to 5 alumina. The ore is lumpy material and of good physical quality. Some trial lots have been used in the mixtures of eastern Pennsylvania blast-furnaces within the past year and have produced satisfactory results.

SPELTER has advanced to 6.20c. per pound St. Louis and 6.35c. New York. At these levels a gain of one-half cent per pound has taken place within the past three weeks. The highest price at which spelter ever sold was in the neighborhood of 6½c. a few years ago.

Concentrates

Most of these are in reply to questions received by mail. Our readers are invited to ask questions and give information dealing with the practice of mining, milling, and smelting.

THE VOLUME of the lithosphere, including the continents elevated above the sea, is 1,633,000,000 cubic miles.

THE SALT in the ocean would make 4,800,000 cubes each 1 mile in dimensions, which, if spread over the United States, would form a layer 1.6 miles high.

RUSSIAN measures of volume may be easily translated by using the following formula: 7 cu. sagene = 343 cu. ft., 12.704 cu. yd., 2.68 cords, or 9.71242 cu. metres; 1 cu. chetverik = 26.24 litres; 1 vedro = 12.30 litres.

THE ATMOSPHERE is equal in weight to 1,268,000 cubic miles of water, which, however, is only one two-hundred-and-thirty-eighth of the volume of the ocean; yet this would be sufficient to raise the level of the ocean 45 ft. on all shores and to submerge an important part of the continents.

ROUND-POINTED shovels should be used where shoveling broken rock from a rough rock bottom. Where a smooth bottom is available or sollars can be laid, square shovels are to be preferred. At the North Star mines, laying sollars and changing to square shovels increased the amount of rock handled per man per shift by 20 per cent.

IN WATER-POWER development the prime requisite for a small power are, first, a stream of water of an appreciable volume, and second, a water fall, a rapid, or a gradient of appreciable amount. In round numbers a stream having a flow of one cubic foot per second will generate one theoretical horse-power for every 10 ft. of fall it has. Thus, a stream flowing 4 cu. ft. per second, and having a fall of 30 ft., could generate 12 theoretical horse-power.

DIAGONAL GRAIN, due to the sawing, is a serious defect in structural timbers, and there is ample justification for guarding against it in specifications and grading rules. The results of tests indicate that a slant in the grain as great as 1 in 45 inches can be admitted without seriously affecting the strength of the timber, but if the diagonal grain is much more pronounced than this, the timber, if heavily loaded, may fail suddenly in cross-grain tension some time before the compression strength of the wood is developed.

IRON DEPOSITS of the 'magmatic type' are due to the separation of the iron minerals from cooling basic igneous rocks. Magnetite is the most common iron mineral and usually carries titanium. The type is well represented by the titaniferous iron ores of Quebec and of eastern New York. From a commercial standpoint this ore is at present largely useless. Changes in furnace practice and improved methods of concentration will probably make it valuable in the future. The nickeliferous pyrrhotite of Sudbury also belongs to this class.

RUBBER SUBSTITUTES are much in demand, and in an effort to find a cheap one interesting experiments have been made with two bituminous minerals, elaterite and tabbyite. Material very similar to rubber can be produced, and good wearing qualities are claimed for it when used in automobile tires and elsewhere. Other varieties of bitumens similar to elaterite and tabbyite have been discovered. One of these, known as wiedgerite, is a soft moist material about the color and consistence of liver, which turns black on exposure. Wiedgerite, which is somewhat high in sulphur, is claimed to be especially valuable for the manufacture of rubber substitutes.

CHLORATES are salts used on matches and in gunpowder. Chlorate of potassium is a valuable salt with important uses. It is made from common cheap potassium chloride, in solution in water, by simply electrolyzing the solution without trying to separate the products forming at the electrodes. It is a simpler operation than the production of electrolytic alkali. Chlorate thus forms in the warm solution, and is obtained by letting the solution cool and the chlorate crystallize out. The ordinary chemical manufacture of this salt was tedious and dangerous; the electrolytic method has practically entirely superseded it.

THE PANAMA CANAL is undoubtedly the best instance of the use of modern excavating methods. Here there are 100 steam-shovels in use, 47 of which are of the heaviest and most powerful type. On account of the very accurate records kept it is particularly interesting to note the outputs recorded in material which is considerably harder than the average. The daily record is now held by a 95-ton shovel built by the Bucyrus company. This machine in 8 hours dug 4823 cu. yd. of material designated as rock and earth, although delayed 160 minutes waiting for cars and for other reasons. More remarkable performances are frequently reported by contractors, but the above is mentioned as it is strictly official.

'STAND-BY' losses constitute a serious element of cost in the running of a steam plant for generating electric current for community supply, where the load changes are great, and at times rapid. In order to handle this change, boilers have to be kept hot, ready for instant service, at a considerable loss of fuel, and when the load is off, the stored energy in these boilers is lost. With an oil gas-producer plant these losses disappear, as the plant efficiency is lowered only a few minutes after starting, and then only a small fraction from its maximum efficiency. Gas is generated the instant the fire is lighted, making it possible to operate a plant constantly at its highest economy by cutting out units as the load falls off, and putting them in as the load comes on.

THE FRASCH process, whereby practically pure sulphur is obtained directly from wells, was invented by Herman Frasch, of Cleveland, Ohio. It is extensively used in Louisiana. The process is as follows: A well is driven in much the same manner as a gas or oil well is sunk, and into it are placed several concentric lines of pipe. Superheated water, introduced through the outer pipe, melts the sulphur, which may be several hundred feet below the surface. Hot compressed air is then forced through the smallest of the pipes. This forms an aerated emulsion with the molten sulphur, which is forced out by hydrostatic pressure between the remaining pipes and discharged in a purified form into large vats where cooling, solidification, and feeding go on simultaneously. The sulphur is then broken up, shipped by rail to the Gulf coast, loaded on ships by machinery, and transported to Eastern coast ports.

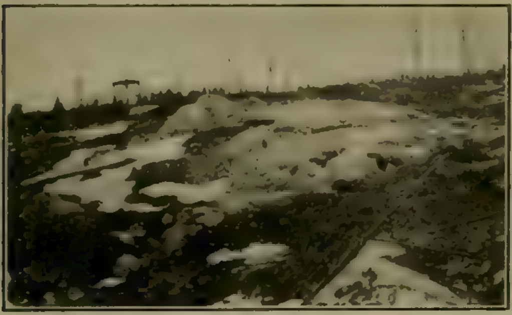
ASBESTOS, according to J. S. Diller, plays a more important part in the national life than is generally credited to it. The well-made asbestos theatre curtain assures the safety of the audience from stage fires. In the home the asbestos covering of the furnace and heating pipes, or of the gas logs in the open fireplace, makes for economy and comfort. Wherever steam is used as a motive power in factories, on trains, or on ships, it is asbestos packing that holds the steam to its work; on the other hand, if electricity is employed the wires are probably insulated by asbestos tape and the adjacent parts are made of asbestos 'lumber.' Asbestos shingles and sheathing make houses cooler in summer and warmer in winter and reduce the fire risk. From the ice-house, where asbestos protects the brine pipes from the heated air, to the foundry, where it shields the workman from molten metal, in the workshop, the home, or the place of amusement, asbestos contributes materially to human welfare.

Special Correspondence

TORONTO, CANADA

Porcupine Ore Occurrence.—Cobalt Shipments.—Revival in Lake of the Woods District.

Porcupine stocks have been steadily declining for some time, but the recent sharp downward tendency has probably been largely due to the publication of a report by the Ontario Bureau of Mines in which the writer, A. G. Burrows, corrects some of the greatly exaggerated ideas prevalent as to the richness of the area. Mr. Burrows, after dealing with the geology of the district, states that the occurrence of gold is associated with the quartz solutions which circulated through the fissures in the Keewatin and Huronian formations, and emphasizes the irregular and non-continuous character of the fissuring, owing to which the quartz structures present a great variety. While some are tabular, though often irregular and lenticular veins traceable for several hundred feet, others are mere veinlets, very narrow and only a few feet in length. Irregular bodies are often found, which may have a width of 10 or 20 ft., but disappear at a distance of 50 ft. The underground extension of the dome-like quartz masses presenting an elliptical or oval surface outline, has not been closely examined, but the report states that in some parts these masses can be seen in contact with underlying rocks at a low angle. This would suggest that they are broad lenticular masses which have filled lateral fissures in the country rock.



OUTCROP OF QUARTZ AT DOME MINE.

The general conclusion reached is that the distribution of gold in the veins is as a rule irregular, occurring along one or both walls, while other portions of the vein may be very low in grade. Spectacular showings occur on many properties, but these are limited to portions of the veins, and therefore, considering the irregular character of certain veins and the quantity of country rock which will have to be mined, the ore must be regarded as low grade. The slump in the market coincident with the publication of this report, if not mainly due to it, has apparently run its course, and the market shows some indications of greater firmness during the last day or two. There are at present four stamp-mills either under construction or shortly to be established, so that it is anticipated that active production will be under way by the New Year. The work is in progress at the Hollinger and the Dome, which will install 40 stamps each, the McIntyre will proceed at once to lay the foundations for a mill of the same capacity, and the Vipond, which had determined on putting up a 10-stamp mill, will delay operations until another level has been reached and more ore blocked out. At the Crown Reserve property a 12-ft. vein of quartz and schist running from the Hollinger has been opened by trenching and found to carry free gold. At the Rea an adit has been pushed for 100 ft. on the orebody at the 200-ft. level. Native gold shows across the width of the vein, which is 4 ft. The Dome has taken over on option, for an amount stated to be $500,000, the seven Jowsey-Wood claims in Carscallen township, Cripple Creek area. The veins contain iron and copper pyrite as well as good showings of gold. Men identified with the Crown Chartered have taken an option on the five Davidson claims in Northern Tisdale at a price reported as $175,000. Two of these claims adjoin the Crown Chartered location. Louis Reyersbach, business manager for the Central Mining & Investment Corporation of London, and Hugh Marriott, consulting engineer for the same interests, recently visited Porcupine and Cobalt.

Although the tonnage of the shipments of ore from Cobalt shows a decrease as compared with last year, the value of the output shows a satisfactory increase, owing to the greater quantities of concentrate and bullion sent out. The output for the first six months of the year was 11,978 tons, as compared with 11,868 for the first six months of 1910. The values of ore and bullion are calculated at $7,927,333 and $6,104,372 for these respective periods. The Coniagas has made remarkable progress lately and has ore of the estimated value of $8,000,000 blocked out. A good find has been made on the Gould Consolidated property on Cart Lake, native silver in considerable quantities having been found in shaft No. 2. A large force will be set at work and development pushed. At the Gleason claim, half a mile from Gillies station, where extensive prospecting had for some time led to no important results, wire silver has been found in a smaltite vein at 45 feet.

The Black Eagle gold mine, also known as the Regina, in the Lake of the Woods district, is being unwatered for examination on behalf of an English syndicate. It was at one time a large producer. The Penniac, another Lake of the Woods property, though just across the Manitoba border, is working in good ore. Visible gold is shown at the bottom of the shaft 76 ft. down, and surface stripping has disclosed high-grade ore. The St. Anthony at Sturgeon lake, another old-time producer, is being successfully worked. An off-shoot of the main vein traced 20 ft. at the 100-ft. level has widened from 18 in. to $3\frac{1}{2}$ ft. and the orebody is reported to assay very high.

JOHANNESBURG, TRANSVAAL

Criticism of Hatch.—Temperature in Depth.

The prediction of F. H. Hatch, in his 'James Forrest' lecture delivered before the Institution of Civil Engineers, that the future output of the Rand would be limited to £1,046,000,000, has caused much adverse comment on the Rand. From the full text of the lecture, now arrived, it would, however, appear that the depth limit was fixed at 6000 ft., or only about 1000 ft. below the present deep mines, and based on calculations made some ten years ago, while it was further stated that he was inclined to the view that a gradual impoverishment with depth does exist. It is some time since the lecturer was on the Rand. Outside a few instances where he has obtained recent information on metallurgical matters, his illustrations and statements are many years behind the prevailing opinion on the Rand. To limit the mining possibilities of the Rand to a vertical depth of 6000 ft. is far behind present-day opinions. The figures quoted with regard to underground temperatures are six years old. Later observations in the deepest mines have shown that the temperature increases only 1° F. for every 255 ft. in depth, and not 1° F. for every 208 ft. as stated. Then as to the gradual impoverishment with depth, there have been numerous instances of late where the grade has improved at the deepest point, which, as a matter of fact, is shown in the lecturer's own statement of value of ore developed. In many of the new deep mines there has been lately marked instances of improvement in depth as compared with the ore now being obtained in the corresponding outcrop mines. There are, of course, cases where the grade has also fallen with the depth, but there is no general gradual impoverishment as the lecturer is now inclined to believe, and both with regard to the depth and future resources of the Rand competent authorities on the spot would have a little hesitation in doubling the lecturer's figures, providing something unforseen does not happen to reduce the grade of ore more than 30% below its present average.

FAIRBANKS, ALASKA

Quartz Development.—New Companies.—Dredging.

The Newsboy Mining Co., which recently sold 100,000 shares of stock to continue development and buy a plant, has already erected a hoist and compressor and will continue sinking. The shaft will be put down beyond the 115-ft. level as fast as possible, so that when the mill arrives the ore reserves will be ample. To further aid development, 100 tons of ore will be milled at the Chena customs mill this month. The 5-stamp Joshua Hendy mill for the Rhoads-Hall property arrived at Fairbanks early in July and is being freighted to the claim. Another month should see the mill in operation. In sinking below the level of the main tunnel, Mr. Rhoads has struck a flow of water that solves the problem of water-supply for the mill during the winter. The last run of 90 tons sent to the Chena customs mill netted a bar worth a trifle over $10,000, besides the value of the concentrate. The Homestake Mining Co. has placed on the market an issue of 80,000 shares to carry on development. This company owns the claim known as the 'Russian Kids', on which a remarkably rich lead was recently found. The McCarty lead also passes through its ground, and it is the intention of the company to drive the adit until this is intersected. The Tanana Hydraulic & Quartz M. Co. has also placed a block of 50,000 shares on the market. This property, better known as the 'Tony Goessman', adjoins the Rhoads-Hall claim and should be intersected by the Rhoads lead. A parallel vein has been opened for 200 ft. on one of the claims. Inside of two weeks the Huntington mill being erected on the Tolovana will be in operation. Enough ore has already been broken to keep the mill busy for some time.

Since putting on a boiler and hoist, Alois Friedrich has cleaned out the shaft, cut a station at the 110-ft. level, and is now sinking to the 200-ft. level. A large body of good ore was found on the foot-wall while cutting out the station. Two samples across the vein have been sent in which assay $94 and $104 per ton. While timbering the shaft, antimony ore was found on the hanging wall. While some of the hitches cut penetrated this for 14 in., the further extent of the shoot is not known. Three tons of the high-grade rock is now going through the test mill. Negotiations are under way by outsiders for a bond on the properties between Vault and Wildcat creeks, owned by Drury, Cathcart, Friedrich, and McDonald.

Sinking is still going ahead on the Fairbanks Quartz Development Co.'s lease, although water and bad ground have been struck. Mr. W. B. Vanderlip, of the Bonding & Leasing Co., has been suddenly called back to Seattle, by the illness of his wife. A shaft is being sunk by contract on the Berry-McIlroy ground on Fairbanks creek. A recent mill-run of 13½ tons of ore from the McCarty Ledge on Fairbanks creek netted the owners $181 per ton. The litigation concerning this claim has been settled out of court, Angus McDougald getting the upper 300 ft. of the claim. Owing to scarcity of timbers, August Hess, of Fairbanks creek, has had to abandon his shaft till the cold weather again tightens up the ground. He is now engaged in surface prospecting. A mill-run of 50 sacks was recently put through the test-mill by Andy Olson of Wolf creek. The rock came from a new find. The dredge owned by the Alaska Exploration Co. and brought from Dawson is being dismantled at Chena and hauled to Fairbanks creek, where the company has considerable ground. It is also the intention of the company to bring in a 10-stamp mill from Dawson, a complete mill being available there. G. G. Lemmons is manager for the company here, while Dupree Lance is consulting engineer.

Rice & King, who hold an option on a Moose creek prospect owned by Alois Friedrich, are now down 25 ft. in the new shaft. The rock is of high grade and a shipment will be made soon to the test-mill. W. H. Isom, of the N. A. T. & T. Co., has wired for the company expert to investigate the quartz mines of this vicinity, with the idea of investing. Mr. Isom has been in Fairbanks but a few weeks. The expert is expected by the first of August.

JARBIDGE, NEVADA

Discoveries on Buckeye and Bacon Claims.—Buster Flotation.—True Fissure.—Wagon Roads and Mills.

Jarbidge is steadily advancing; new veins are being discovered in new territory, additional orebodies are being opened in the older veins, shafts and adits are proving the veins and grade at depth; one mill is running, another is about ready to be started, several mines are showing reserves which will soon warrant other mills; preliminary work has been started on two water-power plants; one new road into the district is finished and another is nearing completion; the telephone line to Rogerson is almost finished and the one to Elko has been started. Two new discoveries of great importance and equal to anything yet found have been made. The first was on the Buckeye claim, over half a mile southeast from the Bourne mine; the second about five miles farther to the southeast and on the Bacon claims. The Buckeye find was made after considerable trenching in from three to seven feet of surface wash and slide matter. The vein uncovered is equal in size and value to the Bluster. It has been traced by numerous surface cuts 100 ft. on each side of the original discovery and is 5 to 10 ft. wide with good ore in all these openings. Some idea of the average richness of this ore can be formed from the amount of gold accumulated by saving the pannings from the small test-samples panned while prospecting during the past three weeks. This saving amounts to over three ounces of gold. The Buckeye is high up the slope of the mountain, in the heavy slide, east of the great quartzite dike, and heretofore has been considered to be of but little promise.

The Bluster property has had several would-be owners bidding for it, but the owners and buyers could not agree. A company has been organized to work the property, and the first offering of its stock at 30c. was quickly taken. The ground on either side of the Bluster shaft has been surveyed into blocks for leasing, the company reserving the central portion, with three leases to the north and three to the south. All of the leases were taken immediately; two of the lessees have found good ore, while the others were so confident that they began at once on a short adit to cut the vein at a depth of 50 to 100 ft. The Bluster vein has been opened on the Success claim; and has been traced down the hillside across the It and the Sliver fraction to the north side of Bonanza gulch. George Wingfield has been in negotiation for the Bluster and adjacent claims. He is now in camp.

The latest find on the Bacon claims in the Cougar Creek basin, or so-called 'Fifth Crater,' promises to be one of the most important yet made in the district. It was made on newly located ground and entirely to the east of that already proved. A large amount of prospecting has been done along the strike of this vein during the past two weeks and numerous openings have been made where good pannings are obtained, extending along it for a distance of two miles. The first discovery was made on Bacon No. 1. It was traced south onto Bacon No. 2 and Bacon No. 7, and north on the Colonel George, Etta B., and Good Luck fraction. The gold found in this vein is quite yellow in color and seemingly high grade. It is also much heavier than that in the west side veins. From the Etta B. some specimens of free-gold ore have been taken which are equal in richness to any yet taken out of any vein in the camp. The Sugar claim of the Crater City Co. lies between the Colonel George and the Etta B. claims, on the line of the vein, but as yet the company has done no prospecting on this vein, being busy with development on the True Fissure vein and the Sugar vein. The True Fissure Co., having proved the value of its vein by surface work, has started development, that can be carried on all winter, in a long adit to tap the vein at a depth of 500 to over 1400 feet.

The wagon-road from Three creek into and up the East Fork of the Jarbidge, which is being built by the True Fissure and Crater City companies is almost finished to the Dixie cabin, from which good pack trails extend on up Fall, Elk, and Cougar creeks to the Third, Fourth, and Fifth Crater mines and prospects. The Crater City Co. has secured the water-rights on the three creeks named and will put in a power plant near the junction of these streams and just below the end of the road, where it is expected at least 200 hp. will be developed. While the mines of the older section of the camp, such as the Blaster, Buckeye, Bourne, and Pavlak, may have richer ore and wider orebodies, the veins to the southeast, along the higher part of the range, seem to be more regular in formation. They have been traced for longer distances and show a more general mineralization and gold content. There seems to be about an equal division of opinion as to the relative value of the two sections, but some of the best engineers in here tend to the belief that the southern part of the district will eventually prove the most productive. The Clark Fletcher mill on the Bourne vein is grinding away and so far has been running quite well for a new plant. The Pavlak mill is expected to start in less than a week.

JOPLIN, MISSOURI

Higher Prices Lead to Renewed Activity.

With the rise in zinc-ore prices, mines have resumed work to a great extent in the sheet ground district north of Webb City, and for the first time in many months extensive mill building is going on in that locality. Among the more recent plants planned is a 300 ton mill for the S. Y. Ramage ground, where a deep run of ore has been found in a number of drill holes and in prospect drifts. In the soft ground camps, where the cost of production is low, virtually every mine that has not been drowned by the recent floods is producing ore or getting ready to produce. In the flooded camps, pumps are working day and night. Galena, Kansas, especially, suffered greatly from high water, thousands of dollars worth of damage having been done to the mines in the Short Creek bottoms. Many of the mines, flooded the middle part of August, will not be in shape to produce ore again for several weeks.

Mining on an extensive scale has been begun by the Kramer Mining Co., operating the old Herald property at Cave Springs, Missouri. A mill with a daily capacity of 500 tons has been constructed. Zincblende is being developed at 240 and 270 ft., while from a shaft to the west of the mill, dirt from the 100-ft. level is milled. The shallow blende occurs in flint; the deeper ore is disseminated through limestone. Numerous drill-holes have shown the formation to be extensive. Faces 80 ft. high are being carried. Throughout the mill and in the underground workings numerous warning placards are posted. Printed instructions on the best method of cutting drifts, the proper ways of handling explosives, etc., are to be found at every turn. The signals are posted both at the mouth of the shaft and at each level to do away with the possibility of incorrect signals.

The erection of a big concentrating plant on the Ideal Mining Co.'s plant, southwest of Joplin, Missouri, has proved again the oft-repeated fact that a tract is not worked out merely because operations have been suspended. Almost a quarter of a century ago the Ideal ground was one of the heaviest producing properties in the entire district. Then it passed the way of numerous other small properties, and lay dormant for years. The new operators, Craver & Barnes, went into the heart of the old district and at a depth of 55 ft. have opened a series of pockets which have been tested both with drill-holes and with prospect drifts. The mill is one of large capacity and is of modern equipment. Another tract that has 'come back' is the old Kohinoor on the Continental ground at Joplin. For years the Kohinoor was an enormous producer; then it passed into the hands of 'gougers'. The ore was found at varying levels from 75 down to 125 ft. The new company working the Kohinoor is composed of Kansas City men. They first drilled the ground and found that an extensive but comparatively lean blende run, underlay the old mine. The ore is of semi-sheet formation and is found at a depth of 175 ft. The shaft has been sunk to this level, and the Quindaro-Continental mine, as the property is now known, is turning out from 60,000 to 80,000 lb. of zinc ore per week, while the production of galena will average several tons per week.

NEW YORK

Dull Markets — International Lead Furnace — Hayden Smelter — Guggenheims and Copper — Finlay Report

The acute conditions prevailing during the past two or three weeks have not been eased in any way. Liquidation is in full swing. The dominant factor in the situation is the conviction, which in the past few weeks has forced itself upon Wall Street, that there is to be no relief from the present strain until corporate regulation is achieved in some form. That the present agitation will be prolonged into the approaching Presidential campaign is one thing upon which there seems to be a unanimity of opinion. There seems to have been no reaction as yet in the Porcupine issues. A sensational find was made on the North Dome this week; there is some new work going forward, a crew has been started on the Daly Taylor and a vein uncovered. Thirty miles to the northeast of Porcupine, near Matheson, in New Ontario, there are some new properties being opened that show quite as well as the average properties in Porcupine, but in the present depression it is hardly to be expected that new finds would receive attention.

Ever since the erection of the plant of the International S. & R. Co. at Tooele, Utah, it has been anticipated that the A. S. & R. Co. would make some counter move. The International smelter is now handling 700 tons of ore per day. The long promised shipments from the Giroux are now apparently farther away than ever, but the lead stack is nearing completion and the bag house and two of the furnaces are so nearly done that the plant may go into commission in November. In erecting a lead stack the Cole-Ryan people got into territory long considered private property by the Guggenheims, and the announcement that the Ray Con. has sold its smelter site to the A. S. & R. Co. may be looked upon as a bid by the Guggenheims for the business of developing Arizona coppers as a counter for the International move in getting into Utah to handle lead-silver ores. The A. S. & R. Co. takes over the partly constructed plant of the Ray Con. at Hayden and agrees to immediately erect a much larger plant of the latest type and to give to the Ray Con. an advantageous long-term contract. The ores of the Miami Copper Co. go to the Greene-Cananea smelter; this will be one contract that the new smelter will be out to get immediately. The Inspiration, the Live Oak, the Keystone, and other mines are developing and the new plant is expected to soon have all the tonnage it can handle. Presumably the new smelter will have a contract with the Chino, where the first section of the concentrator is just being started. Ray Con. is a particular example of the caprice of market followers. A year or more ago, when ore reserves and metal content were largely problematical, the shares sold above $30. Now with tonnage easily calculable and a mill half completed, the stock is quoted at less than $15. Ray Con., Chino, Braden, and Miami make up a string of new producers that are bound to influence the copper situation. Present equipment plans contemplate an annual output of 80,000,000 lb. of copper from the Ray, 50,000,000 from the Chino, and 40,000,000 each from the Braden and the Miami; a total of 210,000,000 to be produced at not more than 8c. per pound. All of this production is controlled by the Guggenheims, except that of the Miami. They control therefore 170,000,000 lb. of new production to be added to the possible 285,000,000 of the combined output of the Nevada Con. and the Utah Copper, and 24,000,000 now said to be coming to the Tacoma smelter from Alaska, making a rough total of 479,000,000 lb. of copper, practically all of which could if necessary be sold considerably under present prices and still show a handsome profit. On the other hand, the situation is working out along normal lines, in that several high-cost coppers are dropping from the producing list. Not all of these shut-downs are directly due to the poor metal market conditions, but if the metal market conditions were better, there would undoubtedly be found a way to keep the properties going. Among those which have discontinued operations temporarily, First National has closed on account of fume trouble; Granby and British Columbia are closed on account of the strike in the coalfields; Imperial of Arizona is in the hands of a receiver; Butte Ballaklava is closed on account of litigation with the Anaconda; Shattuck Arizona is frankly shut-down on account of the low price of copper; Tuolumne in Butte and the Tamarack of Michigan are only producing about one-half full capacity. This is real curtailment to the extent of about 70,000,000 lb., and while some of these mines will in all likelihood resume operations in the near future, the low price of the metal will not hasten the resumption. J. R. Finlay's report on the copper mines of Michigan, prepared for the Board of Equalization for taxation purposes has worked a world of discussion concerning the mines, and, incidentally, concerning Mr. Finlay. The generally unsettled condition of the Lake copper mines owing to the proposed merger now being bitterly fought in several courts, has not served to quiet the shareholders, and they are in a frame of mind to attach possibly too much importance to Mr. Finlay's report. Still, when Mr. Finlay says the future "is much less promising than it is popularly supposed to be," and again that "the limit of profitable working is now in most cases in plain sight," it is little wonder that holders begin to ask if such opinion comes from competent authority or is to be sustained by facts. Mr. Finlay's report in the main, however, does not vary widely from the figures of the Calumet & Hecla committee, so far as the producing properties are concerned, but Mr. Finlay does wipe out the Superior, the Centennial, the Mass, the Gratiot, and some others that are unable to turn out any copper at a profit on a 14-cent market. Michigan copper people are believers in higher prices and insist that while for taxation purposes these properties may have no present value, eventually their ore will be taken out at a profit.

There is a rumor that L. Vogelstein & Co. have taken over control of the Nevada-Utah Mines & Smelters, but this is denied. Vogelstein & Co. have for some time had an eye on Pioche and it is possible that there is some real foundation for the story. Owing, it is said, to a disagreement concerning the dividend policy pursued by the Nipissing company, D. Lorne McGibbon is resigning from the board of directors. His action breaks the strongest connection between the Nipissing and the La Rose companies. Mr. McGibbon is president of the latter and the La Rose has persisted in maintaining an 8% dividend rate and has accumulated a surplus of approximately a million and a half, while Nipissing has been distributing 30% annually and paying out almost dollar for dollar of its net earnings.

HOUGHTON, MICHIGAN

FINLAY'S APPRAISAL OF COPPER AND IRON MINES.

The State Tax Commission recently arranged for an appraisal for taxation purposes, of the copper and iron mines of Michigan, the farmers of the southern part of the State having contended that the mines were not paying their fair share of the taxes. J. R. Finlay was employed to make the appraisal and the following abstract of his report has been telegraphed by the Associated Press. Mr. Finlay values the copper mines at $69,815,000, the iron mines at $119,485,000, and the coal at $861,745.

He says: "Only nine copper companies in Michigan made money during the last five years. If we could assume that these mines would last forever the investor would probably be satisfied with a 5% income and he would probably capitalize their average earnings of $8,240,000 into a present value for the group of $164,800,000. The fact is that these mines are not worth even half of this amount, because their life is not by any means perpetual. On the contrary, their future is much less promising than it is popularly supposed to be. These mines have shown unusual persistence, but the limit of profitable working is now in most cases in plain sight. It must not be forgotten that the tonnage maintained now is three times as great as the mines have averaged in their fifty years of existence. During the past five years," he continues, "profitable copper mines earned $50,937,690.27 over expenditures, but I consider these earnings abnormal, being chiefly due to the great boom of 1906 and 1907. The iron mines earned in five years, $57,551,202 without the benefit of any abnormal prices." He estimates that the Marquette, Menominee, and Gogebic iron ranges will produce 360,000,000 tons more of ore. Mr. Finlay bases his figures on an estimated price of 14c. for copper, and it is interesting to note that his valuation of the Calumet & Hecla properties, while differing in detail, checks closely in totals those upon which it was proposed to consolidate the companies.

KALGOORLIE, WESTERN AUSTRALIA

JUNE YIELD.—BULLFINCH.—A NEW CAM.—RE-TREATING CHARCOAL.—SALTING SANDS.

The gold yield from this State for June was valued at $2,480,000, and dividends were paid amounting to $552,000.

In the main shaft of the Bullfinch Proprietary, at 210-ft. depth, a flow of 3000 gal. of water per hour has been found. Development of $20 ore recently sent shares up from $3.36 to $4.22. The field is very dull on the whole. Experiments are being tried at the Lancefield mine with the Minerals Separation process as used at Broken Hill. The Lancefield ore is somewhat refractory, containing pyrite, arsenic, and graphite, and extractions average 85 per cent.

All the ore milled at the Oroya Links is now being treated direct in the vacuum plant, but results have not been disclosed so far. A new cam has been devised here by W. Birrell. It is cast in halves, and locked on the shaft by the halves being fitted in one another, and by the ordinary Blanton wedge. The cam has been running for 10 days in a custom mill with 900-lb. stamps, with satisfaction; but is now being tried in the Horse-Shoe mill with 1275-lb. stamps. The idea of the split cam is to facilitate removal from the shaft in case of breakage. Its utility has yet to be proved. The cost is about the same as an ordinary cam.

In the June report of the Chamber of Mines, V. T. Edquist discusses the 'Recovery of Gold-Bearing Charcoal on Re-treating Filter-Pressed Slime.' Years ago this slime was dumped from trucks which had a coating of wood ash to prevent the wet slime sticking to the sides. In re-treating, the slime is mixed and passed through trommels with $^3/_{16}$-in. holes, the reject being mixed again, giving a clean product of charcoal, wood, jute, and waste, assaying from 20 to 40 oz. Au per ton as collected. That portion escaping to the agitators is skimmed off. The rubbish is burned, and the product sold to smelters. The charcoal contains as much as 100 oz. Au per ton, it being the chief gold-bearing material. The other organic matter varies from 1 to 7 oz. Au. The charcoal re-precipitated the soluble gold from the old dump, which contains 23% moisture. The bullion from the charcoal carries only 3% Ag, while from the working solution it is 18% Ag, showing a somewhat selective action.

At a customs mill recently 23 tons of ore was milled, and returned $10.50 per ton from the plates, while the sand assayed $220. The mill people would not pay for the sand on this basis, so the customers took action at the Civil Sessions for a balance of $1400 due. Some interesting discussion on battery work took place, including matters of foul mercury, bad condition of plates, etc. The disputed sand contained a lot of free gold which readily amalgamated when tried. Allegations of salting were made, as the plaintiffs had access to the sample room. The judge concluded that the sand contained only $7 per ton, on reckoning the value of some other sand mixed with part of this particular lot. The plaintiffs lost the case with no costs, and retired sadly, with the stigma of having salted the sand sample. It was a clear case. Another case of alleged salting took place about a year ago in another custom plant. A lot of telluride ore was assaying $40 regularly, when it suddenly jumped to $140, the working of the plant not showing such ore to have been treated. This case was more complicated than the one above mentioned, and to save expense the higher value was paid. Two cases of mines employing foreigners who did not understand the English language were recently brought up by the Mines Department. Fines of $150 and $100 and costs respectively were imposed.

General Mining News

ALASKA

The Tanana

The Tolovana M. Co. has started crushing on its property on Willow creek with a new Huntington mill. Water power is used.

It is reported that on both American and Sullivan creeks in the Hot Springs district the extensions of pay streaks have been found which promise a future for the camp. The Sullivan vein was traced to the McVicker claim.

T. A. Utgaard, T. Nerland, and Nels Gieske are to sink a 70 ft. shaft on the Pioneer property on Chatham creek. On an adjoining claim ore assaying $90 per ton was obtained.

ARIZONA

Gila County

D. C. Jackling, president and manager for the Ray Con. Copper Co., is quoted in the press as stating that negotiations have almost been completed by the A. S. & R. Co. to take over the partly built smelter of the Ray company at Hayden. Final arrangements should be completed inside of two weeks. Three units of the Ray concentrator are in commission and the fourth will be ready in a short time. The present output of the concentrator is about 150 tons of concentrate per day. It is rumored that the capacity of the concentrator is to be increased about three times that figure. The principal source of ore for the smelter under the management of the Guggenheims, who are to operate it as a custom plant, will be the Ray mines. Later advices from Boston quote Charles Hayden, vice-president of the Ray company, as stating that the deal has been completed. The proposed early extension of the Southern Pacific from Hayden to San Carlos, 29 miles, and the finding of new ore in the Globe and Kelvin districts, were factors prompting the taking over of the smelter by the A. S. & R. Co. It is stated that E. L. Newhouse, for the purchasing company, offered to pay the Ray company all money expended on foundation work and machinery and to give the latter a low smelting charge for concentrate from the Ray mill.

CALIFORNIA

Kern County

There were rumors during the week that the Honolulu company's properties had been sold to either the Standard or the Dutch company for $10,000,000. This report was denied by William Watson, of the Honolulu company, who stated that there was no foundation for the report. While the machinery for the extraction of gasoline has arrived, the erection of the house will not be commenced until the close of the warm season. Owing to the expense of construction and the competition of the Standard, the plan to pipe natural gas to Los Angeles has been abandoned.

Nevada County

(Special Correspondence.)—Efforts are being made to open promising quartz veins in the North Bloomfield district, formerly noted for its hydraulic mines. Outcroppings of veins are numerous and it is generally believed that the wash from these orebodies yielded the phenomenal gold gravel of the North Bloomfield placers. On the Jenny Lind, McKilliran, King Edward, Bunker Hill, Oriental, White Diamond, and other claims indications are particularly promising. The development thus far consists merely of slight surface trenching, no attempt at shaft or adit work having been made. From the outcrops the quartz is said to be largely free milling, with values ranging from $5 to $50 per ton. A 4-ft. vein has been discovered on the 400-ft. level of the Golden Gate mine. It has been opened about 25 ft. and appears to carry good milling ore. The 10-stamp mill will go into commission within a few days. The Golden Gate is owned largely by Charles C. Haub, of San Francisco. It is reported that the Prudential mine, formerly the New York-Grass Valley, has been purchased by George A. Aldrich, who has recently become interested in the promotion of the California Midland railway. The Prudential has had a stormy career, lack of finances militating against its deep development. A. P. Wilson is superintendent. Along Deer creek, at Nevada City, several men are washing the gravel. The old time pan is much in evidence.

Nevada City, August 26.

The mill at the Alaska mine will be increased from 20 to 40 stamps, and an order for the machinery will soon be placed. All of the latest gold saving devices will be used, it is stated. The principal development is on a drift driven east on the 750 ft. level. A new hoist for the Alaska has arrived at Nevada City and will be hauled there in the near future. It has a 4000-ft. capacity. Gen. W. S. Schuyler, stationed at Fort Riley, Kan., H. A. Moss, of Moss & Co. of San Francisco, and Oliver Crook, of Oakland, all of whom are heavily interested in the mine, have just made an inspection. George St. John is manager of the mine.

Sierra County

Unusually rich quartz has been discovered at the Red Ledge mine at Alleghany. Two chunks assayed, it is reported, at $1000 and $2500, respectively. It is said that the ore did not come from a pocket, but from a vein which is believed to be a continuation of the Tightner vein. The mine is being operated under bond by J. M. O'Brien, who is represented at the mines by C. C. Derby and L. N. Wagner. The 10-stamp mill at the Tightner mine will be in operation in a few weeks.

ALLEGHANY, CALIFORNIA.

Tuolumne County

(Special Correspondence.)—During the next few months operations at the Mohican will be confined to the development of the property, under the direction of E. McHale, the superintendent.

An increased flow of water in the main shaft has caused the Springfield Tunnel & Development Co. to reopen the old 200-ft. shaft, where an electric hoist and a pump will be installed. By sinking a little deeper and driving to the channel it is hoped to drain the workings.

Work has been commenced at the Starr King mine, near Tuolumne, which was recently bonded to a San Francisco company represented here by A. H. Wagner as manager. A hoist, compressor, four machine-drills, and a 5-stamp mill have been purchased, and an effort will be made to have all the machinery housed before the wet weather sets in. The former operators had uncovered good-grade ore in several places, but abandoned the property when the mill, which had just reached the point of completion, was destroyed by fire. The shaft is 800 ft. deep. The rich vein recently uncovered at the 1500-ft. level of the Black Oak mine has been tapped at the 1400-ft. level, and, according to report, the ore is of a remarkably high grade. The Soulsby mine, which the Bagdad-Chase company operated until recently, is to be worked by a number of the miners who were in the employ of the former management.

Under the direction of C. E. Shafer, a long adit is being driven at the Punch Bowl gravel mine, on Table mountain, to tap the ancient channel. The work of erecting a small mill on the Grant mine, near Columbia, will begin at once.

Tuolumne, August 26.

COLORADO

Clear Creek County

(Special Correspondence.)—A body of ore 18 in. wide has been uncovered on the Aetna vein at the Capital mine that assays 14 oz. gold and 26 oz. silver per ton. The discovery was made by Tong. McCluskey & Co., who are operating under lease. H. Holcombe & Co., leasing on the same vein, have shot into a 16-in. streak of ore that mills 8 oz. gold and 11 oz. silver per ton. A pool of Silver Plume lessees has secured the Pelican mill under lease and the plant will be operated on the coöperative plan. On the Senator vein of the Blue Ridge M. & M. Co. a streak of ore 12 in. wide has been found that assays as high as 35 oz. gold and 300 oz. silver per ton. P. H. Stanhope of Denver is manager. B. Converry & Co., leasing on the Millington mine, have started shipments of ore that mills 260 oz. silver per ton. Work will be resumed next week on the Golden Glory property on Saxon mountain. The adit will be driven for several hundred feet to intersect the series of veins controlled. J. F. Puchert is manager. Brad Cowles, operating the Frisco property on Wood mountain, has uncovered a 12-in. streak of sulphide ore that carries free gold. Test assays show as high as 1000 oz. gold per ton. A tramway has been constructed from the National mine in West Argentine, and shipments of galena ore have been started. Charles Coggswell is manager of the mine. Four carloads of machinery for the new Conqueror mill at Empire arrived last week. The plant will be equipped for amalgamation, while cyanide tanks also will be provided. The capacity will be 300 tons per day. G. S. Schneider is manager.

Georgetown, August 28.

(Special Correspondence.)—The Tennessee M. M. & T. Co. has been organized to operate the King Solomon mines, on Chicago mountain. C. S. Birkins is manager for the company. The adit will be advanced 800 ft. to intersect the series of veins on the property.

Idaho Springs, August 29.

Dolores County

John W. Burton and Clinton D. Day, of Salt Lake City, have secured several important groups of claims, including the General Sherman, General Sheridan, General Howard, General Logan, Maid of Australia, Wellington, and Zona K.

La Plata County

Ore assaying as high as $6000 per ton in gold is reported to have been found by lessees on the Buffalo, a claim that lies next to the Neglected. Although the former is an old patented claim, it has been undeveloped until this year, when it was leased to James Dennison and associates of Durango.

Additional specimens from O. N. Kee, the prospector sent out by the grubstake committee of the Denver Chamber of Commerce, are said to be better than the first ones he sent in, about a month ago, which assayed $60 per ton. An engineer will be sent to examine the property.

San Miguel County

It is reported that platinum assaying as high as $500 per ton has been found in a sandstone deposit in the Naturita valley, near Norwood. In appearance the ore resembles the vanadium ore of the same region. The General Vanadium Co. has an option on 26 claims which it obtained through the belief that the ore was vanadiferous.

Teller County

The Kavanagh mill at the Jo Dandy mine, built by Kavanagh & Co., has been opened. It will treat the dumps at the Jo Dandy. The mill has five large tanks of 200 tons capacity each. Ed. Parlin, of Victor, has taken a lease on the Theresa dump on the Golden Cycle estate and will place a washer there. The shaft is on Bull hill. After being closed four months, the Happy Year mine, D. O. Darnell, lessee, has been reopened. Darnell and James Bacon have secured a lease on the Pride of Cripple Creek dump and will start treatment in a short time. Lessees of the Pharmacist mine, on Bull hill, have resumed shipping ore.

By September 1 the Homestake mill, on the estate of the Rex M. & M. Co., on Globe hill, will be in operation. It has been leased to Joe Cooper, superintendent for the Altman Leasing Co., and W. Huxley. Power will be supplied by the Pueblo & Suburban Traction & Lighting Co. Ore from several old dumps will be treated.

IDAHO

Shoshone County

Hypotheek mine, three miles south of Kingston, one of the oldest properties in the Coeur d'Alene, has started concentrating its ores in a small mill, and if the tests are satisfactory, additions will be made to the plant. The property, which was located by Octave Quay more than 25 years ago, has been developed 1000 ft. by adit and shaft. Drifts on the 800 and 1000-ft. levels have opened ore. Recently electric power was installed.

The Federal M. & S. Co. recently made a distribution of 1¾% on its preferred stock, bringing the total dividends paid by the company on this class of stock since its incorporation, eight years ago, to $6,502,426. On common stock for the same period, $2,850,000 has been paid. The dividends on preferred stock this year amount to $629,265, or 5¼%, while the company's customary annual dividends are 7%. The earnings for the current fiscal year to June 1 amounted to $887,000, after all charges, an increase of $405,000, or 86% over the corresponding period of last year. Some difficulty has been experienced through a change in ore content at the Morning mine. A saving of about $3000 per month has been effected through the introduction of the McQuiston tubes. The unit treats about 50 tons per day.

Gold Ridge M. & D. Co., which recently acquired the Buckhorn mine in the Ten-Mile district, Idaho, will install a 15-ton mill on the property and have it running by October 1, it is reported. The Buckhorn group has nine claims and includes a water right on Buckhorn creek from the State of Idaho for milling purposes. A new adit driven this year gives 175 ft. more depth under the upper workings, and when driven 1800 ft. ahead will give a vertical depth of 800 feet.

Press reports state that a consolidation of the Beartop and Orofino properties, in Bear gulch, east of Murray, is planned. Such a merger would end the legal tangle which has tied up the Beartop mine.

The Federal M. & S. Co. has taken a bond for $400,000 on the Cleveland mine, near Mace, adjoining the Standard-Mammoth group, which the corporation acquired from the late Thomas Greenough and Peter Larson for $3,000,000 about seven years ago. The Cleveland is owned by Mrs. James Leonard of Spokane, William R. Leonard of Denver, and Richard Wilson and Walter McKay of Portland. It is reported that the Standard-Mammoth orebodies extend into the Cleveland property, to the line of which the former has been worked. Charles Sweeny, former president, and F. H. Brownell, president of the Federal, started negotiations for the option at a conference in Seattle several months ago. Clayton Miller, of Spokane, general manager of the Federal properties, confirmed the report of option, but declined at this time to give any details.

ILLINOIS

Lawrence County

(Special Correspondence.)—It is reported that the Asiatic Oil Co. has secured options on several oil properties in the Lawrenceville district. The same company has secured a 49% interest in the Indian Refining Co. of Georgetown, Ky., and there are rumors that an American company, capitalized at about $20,000,000, will be formed to operate the holdings. The transactions involve properties valued at $8,000,000, according to report.

Lawrenceville, August 26.

KENTUCKY

(Special Correspondence.)—A new record was made in the yearly production of coal by Kentucky mines in 1910 with a total output of 14,720,011 short tons, states C. J. Norwood, chief inspector of mines and State geologist, in his annual report. Of this amount, 76,108 tons was of cannel coal produced in Bell, Breathitt, Johnson, and Morgan counties. In regard to home consumption, the report states:

"No better coals are sent to market from any mines than are produced in Kentucky, and yet, because of lack of manufacturing enterprises, the increase in the home consumption is relatively slow. Of the output for 1910, 8,800,682 tons was reported as shipped to other States, and it is probable that the actual tonnage so shipped somewhat exceeded that amount."

All Kentucky fluorspar marketed in 1910 was produced by mines in western counties, according to the report. The amount mined was 10,576 short tons, and the amount marketed was 17,008 tons, valued at $124,575. The coal in stock at the end of the year was 1830 tons.

"The year 1910," states the report, "in the number of fatal accidents was the most disastrous in the history of coal mining in Kentucky. This was due to three explosions, as the result of which 50 persons lost their lives. The number of fatalities from all causes was 84, all but one of which occurred underground. Forty-five wives were made widows, and 94 children rendered fatherless."

The report includes a recommendation that laws be passed regulating the quantity of powder that may be carried into a mine each day, and prohibiting shooting on the solid, and regulating the use of electric machinery in mines. One explosion of powder, in which one miner was killed, was due to a trolley wire coming in contact with a keg of powder which was being placed on a car.

Lexington, August 25.

MINNESOTA

ST. LOUIS COUNTY

(Special Correspondence.)—A body of high-grade hematite ore has been discovered at the Camp shaft of the Vermilion & Mesaba Iron Co., one mile east of here. The company took over the holdings of E. C. Kennedy, an attorney of Ely, and began development more than a year ago. It is thought that the Lucky Boy property, on which the discovery was made, has a continuation of the vein of the Chandler mine, which is reported to have produced 10,000,000 tons of ore.

It is stated that more money is being spent on the Vermilion range than at any previous time, and with better results. It is said that several new mines will become shippers, judging from indications, within the next year.

Ely, August 19.

MONTANA

FLATHEAD COUNTY

(Special Correspondence.)—J. J. Hibbard, manager for the Kalispell-Lincoln G. M. Co., is in town from the company's claims on the West Fisher river and reports that the adit is now in 80 ft. and there is a good showing of free-milling gold ore. Two shifts of miners are employed on the tunnel work. The pay-streak in the vein on this property is only about 18 in. wide, Mr. Hibbard says, but is quite rich. It was the intention to put in a stamp-mill this summer, but it has now been decided to wait until winter, when the machinery can be hauled over the snow.

Libby, August 28.

LINCOLN COUNTY

(Special Correspondence.)—Operations are progressing steadily at the Blacktail gold mine, in the southern part of the county, and the mill will soon be in shape to treat the ore which has been mined during the summer. A. M. Balfour and others are working the property on a lease. Three settling-tanks are being built for cyaniding.

J. M. Roberts and Louis Hale have returned from the headwaters of Pipe creek, where they have been searching for Lincoln county's lost coal mine, but state that they have been unable to find the lost vein. This is the second trip that they have made into the country this summer, and they feel confident that they have found the place in which the coal is situated, but owing to the heavy growth of timber, prospecting is difficult.

It is reported here that the Independence copper property, in the northern part of Lincoln county, has been sold to Eastern parties and that it will be operated.

Libby, August 28.

SANDERS COUNTY

(Special Correspondence.)—The Royal Copper M. Co., Ltd., will undertake extensive development work in the spring, according to general report. J. W. Wright, who has the contract for development work, has secured funds to complete the 190 ft. remaining under the contract. The property consists of 12 patented claims four miles north of Belknap, on the Northern Pacific railroad. John H. Nordquist, of Wallace, Idaho, is president of the company.

Belknap, August 28.

SILVERBOW COUNTY

The Tuolumne company, a few days ago, encountered a fine body of high-grade ore on the 1600-ft. level, which is the same body of ore as encountered on the 1400-ft. level, but it is much wider and runs higher in both copper and silver. It is said to be a 22-ft. orebody of bornite and copper glance, and runs on an average 12% in copper with a fine yield of silver. The company is continuing its usual shipments of about 150 tons per day, which runs fully 7% in copper and about 8 oz. in silver per ton. The spur which is being constructed by the Butte, Anaconda & Pacific railway from the Tuolumne mine to the railway connection for the purpose of hauling the ore direct to the smelter at Anaconda is to be ready for operation by September 12, and then hauling ore by teams will be discontinued.

NEVADA

CHURCHILL COUNTY

The Pirouette, controlled by Pennsylvania capitalists, will resume operations in the Wonder district, according to press reports. An electric hoist will be placed, and development work on the 500-ft. level will be pushed. Three or four miles of wire will be strung to connect with the power lines at Wonder.

CLARK COUNTY

The stamp-mill at Newberry mountain will be moved to the Paden property at Crescent peak. The Paden mine has recently shipped to the Salt Lake City smelter a carload of ore which is reported to assay as high as $800.

The New York-Searchlight M. Co. has applied for a patent for the Waterspout group of claims, in the Ormond addition to Searchlight. W. W. Hurt, president of the New York-Searchlight company, is quoted in the press as stating that warranty deeds for surface rights will be given to everyone holding quit-claim deeds or contracts for lots who have their taxes paid, if the patent is granted.

ESMERALDA COUNTY

(Special Correspondence.)—At the Goldfield Belmont, four miles northeast of the Goldfield Con. property, an oreshoot has been opened from which several shipments of ore assaying from $40 to $80 per ton have been made. The driving before reaching the shoot was through faulted ground. A stope on the 300-ft. level, where the discovery was made, also exposed an orebody, $2\frac{1}{2}$ to 3 ft. wide, which assays about $200 per ton.

Seams of quartz assaying $2.50 to $9 have been cut in the dacite in sinking the shaft of the New Jersey M. Co., three miles east of Goldfield. Two or three other companies are working in the neighborhood. This is known as the central dacite formation, and is similar to that found by producing mines farther to the west.

The Florence company is treating 170 tons per day, and is making an improved recovery since using the Akins classifiers and Dorr pulp-thickeners. Operating costs have been reduced, and the capacity of the mill increased. The main shaft has been sunk through bad ground to 880 ft. At the 900-ft. level a station will be cut and driving started north to intersect the rich Reilly ore-shoot. Some good ore has been sent from the 500-ft. level. On the Polverde claim the Jumbo Extension is driving south on the 1030-ft. level, and good ore has been found on levels above the 850-ft. level.

Goldfield, August 21.

Lander County

(Special Correspondence.)—There has been quite a find at Gold Basin, 65 miles east of Fallon. The geological conditions are greatly similar to Tonopah in that the country rock seems to be dacite, while the orebodies are along dikes of rhyolite-porphyry. The orebody thus far is quite wide, the best of it being 6 ft. of $60 ore, chiefly silver, although it pans well in a very fine low-grade gold.

Fallon, August 29.

Nye County

(Special Correspondence.)—The Bath lease on Union No. 2 claim of the Litigation Hill Merger M. Co., is developing what appears to be one of the most promising orebodies in that section of the Manhattan field. The new incline shaft has attained a depth of 250 ft. and reveals an 8-ft. vein said to assay about $32 per ton. This is at a vertical depth of 100 ft. from the surface. The vein is termed a replacement fissure in the lime formation, with the ore so soft it does not require drilling. An electric hoist has been installed and the shaft will be sent to water-level. A pump will be installed later. From 15 to 20 tons of quartz is hoisted daily. An 8-ft. vein of $10 to $25 ore has been opened at a depth of 65 ft. on the Union No. 4 claim. The find was made on the McNeil lease while running a drift to connect the two shafts. The quartz will be treated by the 10-stamp mill on the lease. The winze from the 100-ft. level of the Crescent has entered good ore, and the sinking of the shaft will be carried 50 ft. deeper. At the Tip-Top claim of the Seyler-Humphrey group, the 45-ft. shaft is said to have entered a large body of ore assaying over $25 per ton. Neither wall has yet been encountered. At the Big Four work is going on near the 300-ft. level. The Dexter Con. Leasing Co. is keeping the War Eagle mill running on ore from upper levels of Union No. 9 claim. The inrush of water on the 500-ft. level has increased so that a new pump has been ordered. The entire Manhattan district is showing remarkable activity, but lack of adequate milling facilities continues to handicap operations. In numerous instances leases are compelled to proceed slowly because of inability to have their ore treated promptly. Despite these handicaps an excellent rate of production is maintained. Electric power costs $2 per horse-power month in the district.

Manhattan, August 27.

(Special Correspondence.)—At the War Eagle mill intermediate grinders are being placed between the stamps and the tube-mill to increase the crushing capacity. This step has been made necessary by the steadily increasing demand for reduction facilities. It is reported that ore is being extracted more rapidly than the mill can treat it, and that contracts for ore on the dump will keep the establishment busy for months to come.

Manhattan, August 19.

Storey County

(Special Correspondence.)—The Eagle's Nest-Hailstone Con. Mining Co. has been incorporated with a capitalization of $2,500,000, to be assessed until fully paid up. The incorporation marks the final consolidation of the properties. The secretary is John Matheson. Directors, F. J. Symmes, J. V. De Laveaga, Herman Zadig, C. E. Hudson, and A. S. Wollburg. Principal place of business, Virginia City.

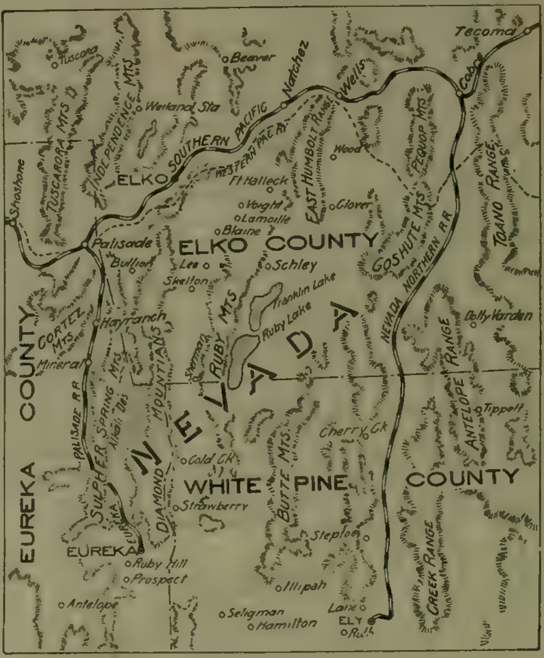
Virginia City, August 29.

(Special Correspondence.)—The weekly report on the Mexican, Ophir, and Union Con. mines shows a gross output of $40,096, which with $4767 from the Crown Point, gives a total extraction from the Comstock Lode of $44,863. This is nearly equal to that of the previous week, when the Mexican made a record for extraction. The water at the C. & C. shaft was from 5 to 10 ft. above the 2500-ft. level through the week, but water was kept from the latter mine by a dam. For safety, no work was done on the 2500-ft. level until the dam was relieved of the pressure, and accordingly much work was done on the 2300-ft. level.

Virginia City, August 26.

White Pine County

(Special Correspondence.)—A silver discovery of great importance was made last week in the southern end of the White Pine mountains and has created much excitement. The vein is said to be 6 ft. wide and to assay from $400 to $600 per ton. The discovery was made on Willow creek, about 25 miles from the Blue Eagle district.



MAP OF EASTERN NEVADA.

The new potash fields of Nye county are situated about midway between Ely and Goldfield, and are attracting much attention. It is said that the ore averages from 7 to 10% in potash on the surface of the ground. Many locations have recently been made, and arrangements have been completed for testing the deposits at depth with a churn-drill, which soon will be operating on the ground. Mining men are of the opinion that the tests will show a large body of water charged with potash, and should this be the case, the future of the new field would seem to be assured. It is claimed that soda in almost a pure state has been found there, from which prospectors are in the habit of making their biscuits. There are also salt deposits in the same neighborhood. Several hundred locations have already been made, and much activity is expected. The new district is near the line of the proposed Ely Goldfield railroad.

Ely, August 19.

(Special Correspondence.)—The Nevada Con. M. Co. in July 1911 produced 5,258,582 lb., against 6,896,429 lb. for the same month last year. The production for the first seven months of 1911 is 37,345,715 lb. During the same period last year 37,848,427 lb. was produced.

Ely, August 26.

(Special Correspondence.)—One more miner injured in the fire in the Giroux shaft last week has died in the hospital, making a total of seven deaths. It is stated that the others have good chances for recovery. It is reported that neither the [illegible] water used to quench the flames caused serious damage.

Ely, August [illegible]

The Nevada Cons. M. Co. has declared its regular quarterly dividend of [illegible] per share.

NEW MEXICO

Socorro County

At the Socorro [illegible] the woodchoppers employed by the power plant were taken off some time ago. Several thousand cords are cut, and by the time this is transported to the power plant the oil engines will be installed.

The Ernestine M. Co.'s mill treated 705 tons during the week and produced [illegible] oz. of gold and silver bullion and 4½ tons of concentrate for the first 10-day period of August. Grading and foundation pits for the new power plant are completed, and construction work has been started. Over a carload of cement will be required for the foundations.

Mogollon, August 18

OREGON

Josephine County

L. L. Jewell has leased the Mountain Lion mine on the Applegate, sixteen miles south of Grants Pass, to C. C. Daniels of that city. The mine has been tied up by litigation, which has been settled, and for a time was a satisfactory producer. There are a 5-stamp mill and two concentrating tables on the property. The ore is a quartz.

TENNESSEE

Polk County

(Special Correspondence.)—The Tennessee Copper Co. has been fighting actions based on alleged fume damages by the Ducktown smelter to timber lands for several years. A verdict recently rendered against the company was for $4650. This particular case has been tried twice previously. One former verdict having been for $10, and one for $32,000.

Ducktown, August 19.

UTAH

Salt Lake County

(Special Correspondence.)—The production of the Utah Copper Co. for the first seven months of 1911 was 53,321,919 lb., against a production for the corresponding period in 1910 of 52,447,279 lb. The production for July 1911 was less than the production for July last year, 7,555,407 lb., against 8,677,851 lb. The production for the month is 1,307,493 lb. short of that of May 1910, 8,862,900 lb., which is the record for the company.

The Utah Copper Co. has declared its regular quarterly dividend of 75c. per share.

Salt Lake City, August 27.

WASHINGTON

Ferry County

(Special Correspondence.)—The Republic Mines Corporation has driven a cross-cut 20 ft. on the 600-ft. level of the Surprise mine and intersected an 8-ft. wide vein, from which the average assay of eight samples is $80.55. The cross-cut is vertically on the dip below the Bonanza shaft and on the hanging-wall side of the vein. Where the cross-cut from the main shaft intersected the vein on the 300-ft. level, the vein is narrow and the ore low grade. A drift in 30 ft. southward shows the vein widening and the quality of the ore improving. On the 200-ft. level the Wallek stope is 25 ft. wide, and the shoot is being mined on the glory-hole system. The ore shipments to Tacoma have been increased, amounting in all, in 18 days, to 30 cars from the Surprise and four cars from the Lone Pine mine.

The Hope company is sinking a shaft, now down 30 ft., on a 6-ft. cross-vein, the ore assaying from $5 to $53 per ton. A raise is going up on the main Black Tail vein, near the winze, on the adit-level. The east drift on the 300-ft. level (formerly referred to as the 100-ft. winze level) is in 30 ft. and shows the pay-shoot on the cross-vein gets longer with depth.

Republic, August 19

CANADA

British Columbia

The British Columbia Copper Co. has declared no dividend for September 1, the regular date for the quarterly distribution. Unsettled conditions due to the miners' strike caused the failure to declare dividends.

Assurance that the Government is to commence work on a pack-trail from Portland city to the British Columbian boundary line has given great encouragement to miners in the Portland Canal district. At present supplies have to be taken to the mines on men's backs, at a cost of 30c. per pound. The first proved property to be tapped will be the Cascade Falls, or Dilworth Bunting group at the junction of Cascade and Cowper creeks, 900 ft. above sea level. The Indian Mines, Ltd., lies a mile northwest. George A. Clothier is superintendent for the latter company.

A luncheon was held August 11 to celebrate the completion of the Canadian Northeastern railroad to the Red Cliff mine. Among those present were J. W. Bryant, representing the Tyee smelter; A. E. Smith, president, and H. Beil Smith, superintendent of the Red Cliff mine; several officials; and representatives of the railroad.

Ontario

(Special Correspondence.)—Re-sampling of the No. 3 vein of the Porcupine G. M. Co.'s property shows 15 ft. of ore assaying $11.70 per ton and 10 ft. of mineralized schist assaying $5.20 per ton, according to C. H. Poirier, manager for the company. The No. 3 vein was found in the cross-cut from the No. 2 workings. The cross-cut reached the south wall before the fire damaged the workings, but the mine recently has been pumped out and the surface equipment overhauled.

Porcupine, August 24.

Yukon

Scroggie creek, for a long time 'tied up' by a mining concession, has been thrown open to prospectors, according to press reports. Many are prospecting there. A large sack has been filled with virgin gold washed on No. 16 Above Discovery, by W. J. Lee and partners. The gold is coarse and brown and resembles somewhat the Jack Wade gold.

Britannia creek, the scene of recent placer discoveries, is being prospected by a large number. The creek is several miles long. Nansen creek is the scene of considerable activity. The pay-streak is said to be 30 ft. wide and the gold is found from the surface to bedrock. The greatest drawback to Nansen creek is the scarcity of timber.

MEXICO

Chihuahua

It is reported that the hydro-electric plant for furnishing power for the mine at Palmarejo has been completed. A new 300-ton mill will be constructed and an aerial tram will be built from the mine to the proposed mill. The old plant has been destroyed. Water-power will be used. The crushing machinery will include stamps and tube-mills. The cyanide process will be used.

Sonora

The new Greene-Cananea mill, the only electrostatic plant in this district, has been placed in operation, and within the next few months the Calumet and Sonora mines will begin to ship ore in quantities larger than ever before. The old mill continues to operate, although it had been operating only one shift before the completion of the new mill.

The new mill was constructed on account of the refractory nature of the concentrates, which in most of the ores contain copper, silver, zinc, and lead. Except in the case of pure zinc and lead ores the company was unable to treat the concentrates at a profit and they were stored, with consequent loss from oxidation. The oxidized concentrates will be given a cyanide bath before treatment.

Company Reports

GOLDFIELD CON. JULY REPORT

The report of J. F. Thorn, general superintendent for the Goldfield Con. M. Co., for July, shows: Total production, 29,253 tons, containing $848,429.44, an average of $29 per ton, of which 29,174 tons was milled with an average extraction of 94.55%, and 79 tons of an average value of $46.80 per ton was shipped. The net recovery from all the ore was $27.42 per ton. The total net profit was $582,021.68, or $19.89 per ton. Development included 4078 ft. The total cost of mining, development, transportation, milling, office and general expense was $7.66 per ton, distributed as follows:

Mining:		
Development	$0.97	
Stoping	2.46	
		$3.43
Transportation		0.07
Milling		2.27
Marketing		1.12
General expense		0.33
Bullion tax		0.31
Marketing ore shipped		0.03
Construction		0.10
Total cost of operation		$7.66
Miscellaneous earnings		0.13
Net cost per ton		$7.53

In the Combination mine, on the third level, about 300 ft. north of the shaft, ore of a good grade has been found. It is probably the downward extension of the 136 orebody on the second level. In the Mohawk the 163 and 155-ft. drifts on the 150-ft. level were extended 100 ft. and produced 400 tons of ore worth $20 per ton. The 354 sill was extended on the hanging-wall side and produced 245 tons of ore worth $58 per ton. The 490-ft. intermediate, 60 ft. below the 450-ft. level, produced 161 tons of ore that averaged $30 per ton. This orebody is probably the downward extension of the north end of the 354 orebody. The 499 was extended about 50 ft. and produced 150 tons of $13 ore. In the Clermont the 408 sill was extended along the 413 intermediate and produced 1576 tons of ore that averaged $53 per ton; 306 N., on the 600-ft. level, mentioned in last month's report as the probable extension of the 354 orebody, has been considerably extended, and produced 870 tons of $12 ore. In the Laguna the 303 E. raise from the 600-ft. north drift of the Clermont has produced 122 tons of $20 ore. The 329 intermediate, probably the upward extension of the 303 E. orebody, produced 377 tons of $12 ore. The Jumbo has produced 365 tons of ore that averaged $14 per ton. The indications are that this mine will produce a large tonnage of about $15 ore. The mines, as a whole, are looking exceptionally well.

ALASKA UNITED GOLD COMPANY

This, the youngest of the three mines of the Treadwell group on Douglas Island, Alaska, operates two mines, one on the 700-Foot Claim between the Treadwell and Mexican, and the other, the Ready Bullion, south of the Alaska Mexican. Details regarding the operation of these mines have been given from month to month in the *Mining and Scientific Press.* In the report of the superintendent, Robert A. Kinzie, for the year ending December 15, 1910, a great deal of interesting technical information is given. The Ready Bullion mine, at the date of the report, had in sight below the 900-ft. level 1,754,350 tons of ore of which the average assay value was $3.02. In 1910, 232,330 tons having an average value of $2.43 were milled. Since 1900 the average of the ore milled has assayed $2.06, showing that the ore now in reserve, despite increased depth, is worth more per ton than the average already milled. Indeed the reserves in 1902 were estimated at only $2.03 per ton. In the operation of the mine in 1910, 151,460 tons of ore and 2756 of waste were broken. An average of 10.12 machine-drills were kept busy with an average duty of 36.12 ft. drilled per shift and 23.06 tons broken. The cost was $8.35 for labor, $2.43 for explosives, and $4.96 for supplies, power, repairs, and incidentals. In stoping, 1.61 tons was broken per foot drilled; in development, 0.22; and in cutting out stopes, 0.31 tons. The total number of feet of holes drilled in the mine in the course of the year was 241,679. The average of the assay values by levels was 1050-ft., $1.99; 1350, $3.07; 1500, $4.07; 1650, $2.86; 1800, $2.74. From the 700 mine 188,329 tons was milled, and in it 865,223 tons is in reserve. Here again the average assay value of the present ore reserve, $2.51, is higher than the average of the ore so far sent to the mill, $2.33. The tons broken per machine-drill shift was 30.41, and feet drilled 34.37. Costs were: labor, $6.96; explosives, $2.84; supplies, power, repairs, and incidentals, $4.55. A central hoisting plant designed to handle 5000 tons from a depth of 3500 ft. in 20 hours is now being erected at the 700 mine and will be used to hoist ore from it, the Treadwell, and the Alaska Mexican mines. The head-frame will be built of steel and the power-house of reinforced concrete.

Decisions Relating to Mining

Specially reported for the MINING AND SCIENTIFIC PRESS.

RECOVERY OF MINING CLAIM—PLEADING AND PROOF

In an action to recover certain mining claims a particular location was not mentioned in either the complaint or answer, but the defendant claimed some rights in reference thereto. On the trial evidence was properly admitted showing a forfeiture of the location by a failure to perform the required assessment work on the plaintiff's behalf without an express plea.

Harper *v.* Hill, (Cal.) 113 Pacific, 162, Jan. 1911.

MINERAL LEASE—IMPLIED COVENANTS AND DUTY OF LESSEE

An exclusive lease giving the lessee the right of exploring for and taking minerals from certain lands for a long term, based on a cash payment and royalties, implies a covenant on the part of the lessee to make proper and reasonable diligent explorations and development of the premises, and such a lease may be forfeited for breach of the implied covenant on the part of the lessee to make such exploration and development. But if a lease to explore for and take minerals expressly provides when and how the exploration shall be made, then there is no implied covenant. However, a provision that failure to begin prospecting on the land, or on other land within four miles thereon within one year, should defeat the lease, does not preclude forfeiture for the lessee's breach of the implied covenant to diligently explore and develop the premises.

Mansfield Gas Co. *v.* Alexander, (Ark.) 133 Southwestern, 837. Jan. 1911.

JURISDICTION TO DETERMINE TITLE TO MINES

The land department of the United States is not a tribunal authorized to determine the title to lands, but it is only the medium through which parties may acquire the title of the United States. Accordingly its functions are mostly administrative and only incidentally judicial, and it only determines the existence or non-existence of alleged facts in order to enable it to select the person who is entitled to purchase. The proceedings before the land department is to acquire title and not to determine who has title. Therefore in an action by an owner of a mining claim against the owner of an adjoining claim for damages for encroaching on the former's claim, and where both parties allege title to the property in question, it is not a question for the land department to determine, but is one of law for a court of competent jurisdiction. And this rule applies in cases where there is an adverse claim.

Lightner Mining Co. *v.* Superior Court, (Cal.) 112 Pacific, 909. Jan. 1911.

Personal

Professional men are invited to send news of their engagements and travels. Such news is interesting to friends.

Harry Paul was in San Francisco.

George Walker is at Salt Lake City.

T. T. Read has returned from Nevada.

Z. Cushing has returned from Alaska.

C. B. Naremore was in San Francisco.

W. R. Hamilton has been at Coalinga.

Pope Yeatman has left Salt Lake City.

C. B. Lakenan has returned to Nevada.

F. Augustus Heinze is at Salt Lake City.

E. F. Burchard has been at Trenton, Georgia.

R. A. F. Penrose, Jr., has been in San Francisco.

W. E. Defty is examining the North Star mine, Arizona.

Edmund Juessen has returned from Pittsburg and the East.

S. F. Shaw will be in Porcupine during September and October.

D. C. Jackling and F. G. Janney have returned to Salt Lake City.

Oliver B. Finn is in New Mexico investigating a dredging property.

J. B. Tyrrell, of Toronto, has returned from a short visit to London.

W. J. Loring was in San Francisco and has gone to Porcupine, Ontario.

Frederick G. Clapp is conducting geological work in Tennessee in search of oil or gas.

C. B. Whitwell has gone to White Horse, Yukon Territory, to report on some gold properties.

Joseph T. Terry, Jr., of Butte, Montana, is now superintendent of the Dan mine, twelve miles from Baker, Oregon.

H. H. Johnson and J. T. Hoffmann have gone into partnership, with offices at 216 Moorgate Station Chambers, London.

Carl F. Dietz and Dyke V. Keedy, of Boston, have gone to Nova Scotia to examine two copper properties in the interest of Halifax people.

H. W. Hardinge has just returned to New York from an extended trip in the West, and expects to go to Europe on professional business this month.

F. M. Field and T. H. Teal have completed their examination of the Commonwealth mine at Pearce, Arizona, and have returned to Los Angeles.

D'Arcy Weatherbe has severed his connection with Orsk Goldfields, Ltd., and is examining gold mines near Nikolaievsk for the Russian Corporation.

Frank H. Probert is at the Ray Central Copper Co. property at Ray, Arizona, for ten days; from there he will go to the Alamos district, Sonora, Mexico.

Edwin Higgins has returned to Los Angeles after a five months stay in the Randsburg district. He has reopened his office at 312-314 Trust & Savings building.

Ernest Grave has stopped all work for the Candelaria y Anexas, at Pinos, Zacatecas, Mexico, and has left the property in the hands of a caretaker. Mr. Grave will be at Tampico, Tamaulipas, Mexico.

C. H. Repath, who was consulting engineer in charge of the construction of the International smelter at Tooele, Utah, is to have charge of the rebuilding of the United Verde smelter at Jerome, Arizona.

The San Francisco Section of the Mining and Metallurgical Society of America will hold a meeting at 1026 Crocker building following dinner at 6:30 in the men's grill room of the Palace Hotel, Monday, September 4. Visiting members are especially invited to attend.

Risks in Modern Industry. *The Annals* of the American Academy of Political and Social Science, Vol. XXXVIII, No. 1, July. 317 pp., index. Philadelphia, 1911.

Uniform Child Labor Laws. Supplement to *The Annals* of the American Academy of Political and Social Science, Vol. XXXVIII, No. 1, July. 224 pp.; index. Philadelphia, 1911.

The Johnson Electric Zinc Furnace. By Joseph W. Richards. From Trans. Amer. Electro-Chem. Soc., Vol. XIX., pp. 311-316, 1911. Description of an American furnace of large possibilities.

Contribution of the Mining Profession to the Conservation of Our Natural Resources. By H. S. Drinker. Pam. Pp. 19. 1911. A scholarly address delivered by the president of Lehigh University at the exercises commemorating the twenty-fifth anniversary of the founding of Michigan College of Mines.

Porcupine Mining District. The *Canadian Mining Journal's* Porcupine Series, Vol. 1. Pp. 86. Ill., maps. Toronto, 1911. This is a re-publication in convenient form of the excellent articles on the new Ontario gold district, that have been printed by our enterprising Canadian contemporary. We hope that numerous additional volumes may follow.

Geological and Mineral Resources of the Arbuckle Mountains, Oklahoma. By C. A. Reeds. Oklahoma Geol. Surv., Bull. 3. 66 pp.; ill., map. Norman, (Okla.) 1910. A convenient summary of the essential facts regarding an important area. The mineral resources are in the main non-metallic, though iron and manganese occur in quantities of possible significance.

Geology and Ore Deposits of the Blewett Mining District. By Charles E. Weaver. Washington Geol. Surv., Bull. 6. Pp. 104. Ill., index, map. Olympia, 1911. A welcome account of the mining district often known as the Peshastin, and situated in south central Chelan county. Both placer and quartz mines have been worked and the total output to date is estimated at $1,700,000.

Copper Deposits of the United States. By Walter Harvey Weed. U. S. Geol. Surv., Bull. 455. Pp. 166. Ill., index. Washington, 1911. This is a welcome addition to the literature of ore deposits since it is a re-description of the classic mines of the Eastern States, written by an engineer especially qualified for the task. Mr. Weed precedes the descriptive chapters by a classification of the deposits, a study that will be of especial interest to students of ore genesis.

The Resources of Tennessee. Pub. by the State Geol. Surv., Nashville, 1911. The aggressive State Geologist of Tennessee, G. H. Ashley, has undertaken to satisfy demands for prompt information regarding the resources of his State by means of a little monthly publication of which the issue at hand forms the second. It includes papers on 'The Camden Chert—An Ideal Road Material,' by Mr. Ashley; 'The Fernvale Iron Ore Deposit of Davidson County,' by W. A. Nelson; 'Cement Materials of Tennessee,' by C. H. Gordon; and a few briefer notes.

The following publications of the United States Geological Survey have recently been received: 'Reconnaissance of the Ore Deposits in Northern Yuma County, Arizona', by Howland Bancroft; Bull. 451, 131 pp., ill., maps, index, 1911. Electric Hoist at Ray

The large electric hoist recently installed by the Ray Consolidated Copper Company at Ray, near Kelvin, Arizona, at its No. 1 shaft, has attracted a great deal of attention on account of its many unique features, the heavy loads handled, and the large production required from this shaft. The following detailed description has been prepared by the builders, The Wellman-Seaver-Morgan Co., and is published to supplement Mr. Dinsmore's general account of this mine, appearing elsewhere in this issue.

The hoist is intended to handle a net ore load of 12½ tons, together with a skip weighing 16,000 lb., from a maximum depth of 500 ft., hoisting at a speed of 300 ft. per minute. The hoist operates with balanced skips entirely, one of the drums being keyed fast to the shaft, while the other is being driven by a powerful band-friction clutch for the adjustment to different levels, as desired. The hoist is equipped with an alternating motor, 440 volt, 3 phase, 60 cycle, with a full-load speed of 430 r.p.m., and is rated at 300 hp. This motor is fitted with a rope wheel, 44 in. diam., having turned grooves for 32 one-inch ropes, the motor being connected to the hoist by a rope drive engaging the 13-ft. rope wheel on the pinion shaft of the main hoist. The idea underlying the design of this hoist is that the motor for running the hoist shall operate continuously in one direction, while the drums may be started, stopped, or reversed. The principal electric loss in hoists operating by alternating-current motors is occasioned by the starting of the motor, which, when the motor is large, becomes serious. It is therefore desirable not to be obliged to start the motor at each trip, since, when the motor is running idly, the current required by it is limited, so that the peak losses are very materially reduced. In this type of hoist the load is gradually accelerated by applying the powerful clutches.

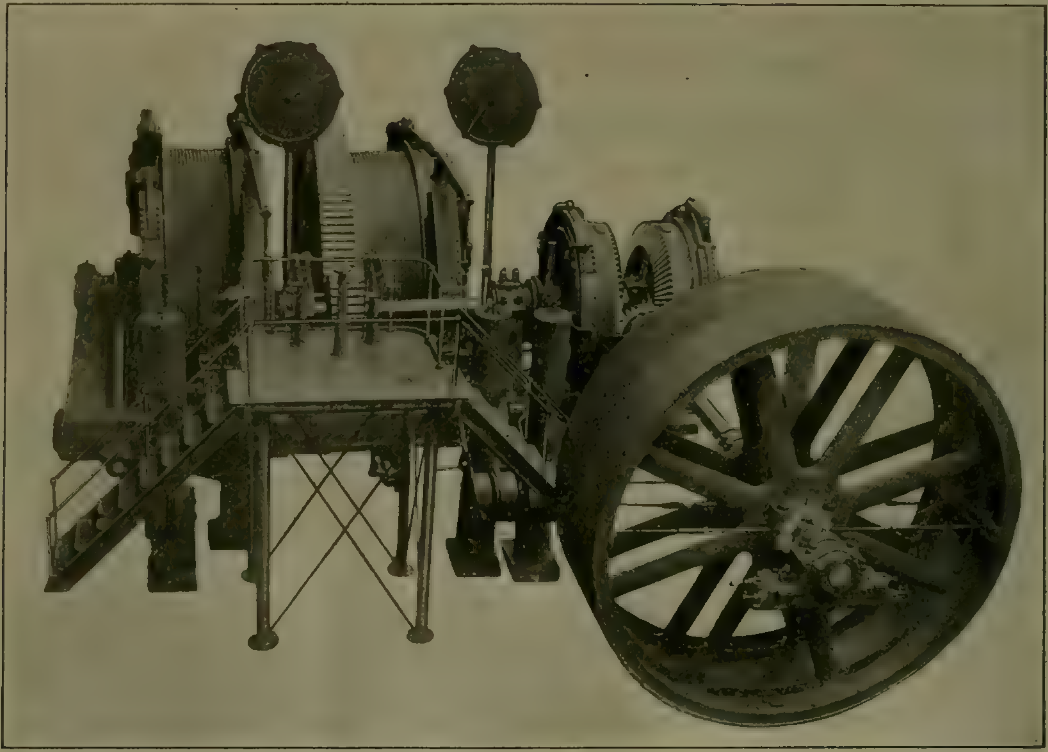

FIG. 1. GENERAL VIEW.

The accompanying illustrations show various views of the hoist and its details. Fig. 1 gives a general view of the hoist with the exception of the motor and rope drive. The power is transmitted from the motor to the hoist by means of a bevel-gear driving and reversing system. The pinion, which is of forged steel with machine-cut teeth, engages in two cast-steel, machined, bevel-gears, running in opposite directions, which are completely enclosed in the steel casing, the top half of which is removed in the accompanying illustration. Both these gears are loose on the immediate shaft, being fitted with bronze bushings of ample proportions, easily removable for renewal, while on the back of each of these gears is a friction ring which the band-friction clutch engages. These clutches are securely keyed to the intermediate shaft, and are operated by vertical-operating cylinders, the clutches being applied by weights and released by the operating cylinders. The cylinders are controlled in their movement by a cataract cylinder filled with oil, the power used in the operating cylinder being compressed air taken from the air mains supplying the mine, but there is an auxiliary motor-driven air-compressor in the engine-house. This automatically provides air for operating the hoist should the mine pressure be shut off or go below a certain predetermined pressure. Both of the clutch-operating cylinders are worked by single lever to the operating platform and so connected that either clutch may be thrown in at will, but both clutches can never be in at the same time, and one clutch must be wholly thrown out before the other can be thrown in.

The intermediate shaft is extended and fitted with a forged-steel, machine-cut pinion, which engages in the main driving-gear for the two drums. This gear is of cast steel with machine-cut teeth, and is approximately 16 ft. in diameter. The drums are 12 ft. in diameter and grooved to carry about 600 ft. of 1¾-in. hoisting rope. The loose drum is fitted with a powerful band-friction clutch of the modified Lane type, illustrated in Fig. 2. The clutch is of massive proportions, with a 12-ft. driving-ring and built for a possible working load of 50,000 lb. The clutch-disk is of cast steel, and the fixed and movable arms engaging the driving-band are of annealed-steel castings. Ample adjustment is provided for taking up the wear of the band, which is of high-grade steel lined with basswood linings. Lifters are provided as shown, for equalizing the clearance of the bands from the clutch ring when the clutch is released. Each drum is provided with a powerful post brake, the beams of which are built up of steel plates and angles, as shown, and fitted with basswood wearing-blocks 11 in. wide.

The brakes, as well as the main clutch, are each operated by means of a combined air and cataract cylinder fitted with floating valve-gear under control of a hand lever on the operator's platform. The design of the connections is such that the brakes are set by means of weights and released by the air cylinder. Dial indicators are provided, one being driven from each drum for showing the position of the skip in the shaft. The skips are not provided with safety dogs or appliances, on account of the extreme weight and bulkiness of such equipment for a load of this magnitude, but an over-winding device is provided to prevent the skips being carried into the sheaves through any neglect of the operator. This device consists of two limit-switches, one for each skip, so placed that when the skip is carried beyond the highest point for dumping, it will come in contact with an extended lever fitted with a roller, which lever, moving through an arc of 35°, disengages the contacts. These limit-switches are connected by wires to solenoids operating quick-opening valves in the supply-pipes to the air-cylinders, so that if the skip passes a given point in the shaft, the solenoids come into action and at once release the pressure from the operating cylinders, allowing the weights to apply both the powerful brakes and throw out the clutches, bringing the hoist at once to a stop without the necessity of stopping the motor.

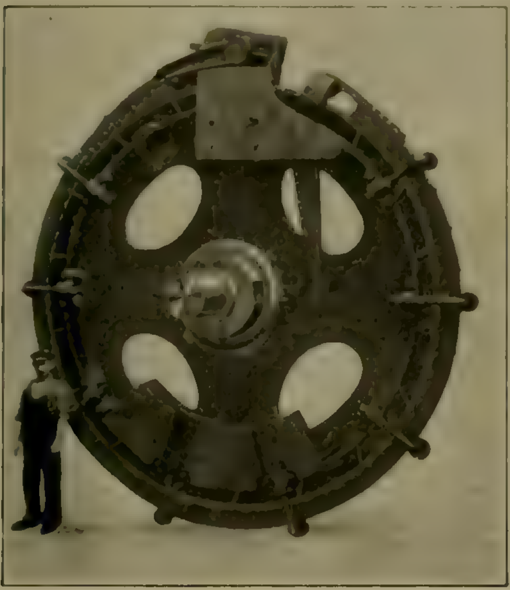

FIG. 2. CLUTCHES.

The hoist is of massive proportions throughout, designed with a high factor of safety, so as to guard against any possibility of delay from breakage or derangement while handling this immense tonnage. The compartments of the main hoisting-shaft are 6 by 7 ft. in the clear, having a distance of 7 ft. 10 in. centre to centre of compartments.

The ore-skips are constructed of ½-in. steel plate, 4 ft. 10 in. by 5 ft. 2 in. by 10 ft. in depth, while the total height from the centre of bottom swing-bearing to the top of the universal socket taking the 1¾-in. diameter hoist-cable is 18 ft. The bottom swing-bearings and saddles are of cast steel, each having a bearing area on the bottom of the skip of 15⅛ by 45 in. The swing and saddle shafts are each 5½-in. diam., collared and placed on 22-in. centres. The dumping rollers are of cast-steel bronze, bushed with cast-steel trunnions 5½-in. diam. The cross-head frames are 1¼ in. thick by 20 in. deep, and are provided with special cone roller bearings taking the lower member of the cable socket. This construction permits the cable to turn or twist freely. The forged-steel skip frames are 1¼ by 12 in. in cross-section. The inside front and back of the main skip body is protected by 2½ by 1 in. bars extending from the mouth of the skip to a distance of 3 ft. 6 in. from the bottom. These bars are riveted to auxiliary plates ¼ in. thick, which are bolted to the main body by means of special ⅞-in. bolts. This permits of easy access in removing the bars for repairs or renewal. No supplies, waste rock, or men are handled in the main hoisting shafts, but a smaller electric hoist is used in an auxiliary inclined shaft at each plant for handling waste rock and supplies, while the men have access to and egress from the workings by means of an easy stairway in these inclined shafts.

IRON ORE movement down the Lakes during 1911 has been sensibly less month by month than that of 1910. According to figures compiled by the *Iron Trade Review*, the fleet moved, to August 1, 1910, 21,863,549 tons, and to August 1, 1911, 14,064,291 tons, a decrease of 7,799,258 tons. If the movement of the remaining months of the present year should equal that of last year, the total shipments for 1911 would be approximately 34,000,000 tons. It is now clear, however, that no such movement will mark the remaining months of the year, and total shipments are likely to fall under 30,000,000 tons. Following is the table:

	1910.	1911.
April	1,520,305	331,645
May	6,081,358	3,684,819
June	7,316,592	4,826,505
July	6,945,289	5,221,373
August	6,964,381	....
September	6,273,832	....
October	4,877,441	....
November	2,641,886	....

EDITORIAL

THE American Peat Society will hold its annual meeting at Kalamazoo, Michigan, September 21 to 23 inclusive. An interesting program has been arranged.

BUTTE was the scene of a bad accident this week as a result of men insisting on riding on a cage loaded with drill steel. Impatience of restraint even when for their own good is sadly characteristic of North American miners.

CONSERVATIONISTS are to meet at Kansas City, Missouri, September 25 to 27 inclusive. The call for the National Conservation Congress provides for selection of delegates by Governors, Mayors, County Commissioners, Chambers of Commerce, Universities, and Societies. A large and representative attendance is expected.

FIRES have been started under the boilers at the mill of the Chino Copper Company and actual production of concentrate will be under way before the end of the month. Record time has been made at this property since the present management took hold a little over two years ago. It is just fourteen months since construction of the mill at Hurley began.

SUFFICIENT attention has never been devoted in the United States to selection of candidates for the Vice-Presidency. As *Harper's Weekly* truly observes, as a rule the candidate "is not selected at all, but the office is scrambled for in convention as the delegates are leaving, and it is a gamble whether a fit man gets it or not." Providence has been kind to the country through more than one administration in preserving the life of the President.

LEASING has become the established method of working mines at Cripple Creek, Colorado, and the district was therefore thrown into confusion when the big companies began to hold up applications last month. An act had been passed by the Legislature that, in the opinion of attorneys, would have placed on the owning company responsibility for lessees debts. Attention having been thus forcibly called to the practical result of the law, the Governor decided to veto the bill.

AN INVESTIGATION of the Kansas natural-gas fields is to be made on behalf of the Kansas City public utilities commission, by Mr. Erasmus Haworth. The Kansas Natural Gas Company, despite heavy investment in lands, leases, and pipe-lines, has found itself unable to furnish gas to its customers as freely as in former years. Loss of its supply of fuel gas would be a severe blow to Kansas City, and the public is not unnaturally much exercised at the prospect. Ultimately the supply of gas is sure to fail, but prolonging its life even a few years will mean much to the community. We heartily commend the action of the commission in calling in expert service. It is another indication of the new order of things in American municipal government. Incidentally, the whole situation re-emphasizes the necessity of conserving by every possible means the supplies of natural gas that remain in other States as well as Kansas.

AUSTRALIA'S dependency, Papua, has remained little known, owing mainly to the difficulties of tropical exploration and the fact that Australians have been busy at home. Recently a party of Federal officials visited the territory and we reproduce this week an account of the mineral resources of the island, prepared for our Australian contemporary by Mr. Hugh Mahon, one of the members of Congress accompanying the expedition. Apparently the veins on the island are important, and as the country becomes better known good mines will be developed.

WILLOUGHBY'S CONSOLIDATED has joined the ranks of the dividend payers after many discouraging years. Formed in 1894, this great Rhodesian company now controls 1,339,000 acres, including over 3000 gold claims. Development of such an estate would be slow anywhere, and in Rhodesia, where the work of the pioneer is still far from complete, the period between flotation and dividend paying is not unnaturally long. American engineers are glad to extend congratulations to the management of the company and to the consulting engineer, Mr. Walter Currie, whose visit to the United States is pleasantly remembered.

AIR-COMPRESSORS do not exhibit good efficiency at high altitudes, because of the low barometric pressure. This is a familiar phenomenon to mining engineers, but the similar effect which altitude has upon gasoline engines is not so well known. At 18,000 feet an automobile motor is reduced to one-half its normal horse-power and there is a greater difficulty in securing proper cooling of cylinders because of the low boiling point of water. At Quito, Ecuador, at an elevation of 9000 feet the use of automobiles is much restricted by the abrupt changes of altitude met in traveling in the vicinity, motors adjusted to operate at the higher levels giving poor service on the plains below.

LEASING the public coal and oil lands is a policy now frequently proposed. In an address delivered at Houghton, Michigan, August 9, and reproduced in the *Mining and Scientific Press* August 12, Mr. George Otis Smith, Director of the United States Geological Survey, discussed the whole matter of the mining industry and the public lands from what may perhaps fairly be considered the 'Administration' point of view. In this week's issue of the *Press*, Mr. William Forstner analyzes the proposed application of the leasing system to California oil-lands and states forcibly the difficulties that must be met. In still other articles now in preparation other phases of the matter will be taken up. The proposal is of such profound interest to the whole mining industry that every engineer can well afford the time needed to study these articles and to make his own contribution to the discussion. Letters from our readers will in this case be particularly welcome.

THE NEW SPIRIT in old China is well exemplified by five full pages of display advertising of the Imperial Railways of China in our excellent contemporary, the *Far Eastern Review*. China is passing through a stage in her development not dissimilar to the period when 'States Rights' were a burning issue in our own politics. Among the rights claimed and exercised by the eighteen provinces are the minting of coins and the construction of railways. Recently the central government has taken upon itself these rights, since modern thought so clearly proves that they may best be performed by a central authority rather than left to the vagaries of provincial officials. This, indeed, is evidenced by experience within the borders of the Flowery Kingdom, as the Imperial Railways of North China now pays handsome dividends, while the Canton provincial company collected and spent some twenty million pesos, with only one hundred miles of road as a net result. Apparently China has a firm policy at last, and correspondingly great progress may be expected.

GEOLOGISTS are in high favor in any mining district when they are sufficiently optimistic, but are regarded as extremely theoretical when they urge caution. Mr. A. G. Burrow's report of Porcupine is considered unduly pessimistic by the local press, because, apparently, of his statements as to the irregularity of the occurrence of the rich streaks of ore. That the deposits of Porcupine will prove to be large and of low grade rather than small and of high grade is the common opinion of engineers who have studied the district. The *Porcupine Press* calls upon Mr. Burrows to agree "that no geologist has to date ever opened up a mining country." This is positively funny in view of the presence of Mr. Malcolm Maclaren at Porcupine at this time for Bewick, Moreing & Company, to say nothing of the services of Mr. W. G. Miller at Cobalt, and the whole succession of geologists who have contributed so largely to the 'opening up' of Ontario and the Lake Superior region.

PROSPECTING by means of drills is becoming increasingly common as new and better types are being perfected. In a large way low-cost and security of results stand in antithesis. Drilling a hole, and getting a true sample of the rock drilled, are two different things, and methods must be varied with conditions. In the Joplin district it has long been considered impracticable to do core-drilling; not that a core could not be obtained, but that the cost would be out of proportion to the benefits. This week Mr. Otto Ruhl describes for our readers recent work in that district accomplished with the calyx drill, and the showing is certainly one that promises much for the district as a whole. It will not do, however, to jump to the conclusion that loss of diamonds always off-sets the speed of work with a diamond-drill. In Nova Scotia it has been found that the diamond loss was practically the same as the shot loss, while labor costs with a new diamond-drill were less. No doubt the character of the ground and the conditions of the drill explain the difference. In developing the porphyry copper deposits the churn-drill has been found both cheap and safe. In outlying corners of the world where transportation costs mount up, the hand-drill has proved to have peculiar advantages. Engineers should be familiar with each type and should study the range of usefulness of each. Get the best for your particular piece of work. There can be only one 'best' in a given case.

Steam-Shovels in Mining

A purist might be inclined to question the use of steam-shovels for mining, as it is perhaps doubtful whether the latter term can be applied with precision to sub-aerial excavations. But engineers are more anxious for results than for precision of speech, and conspicuously successful results have followed the use of steam-shovels for mining ores that fortunately occur in large bodies near the surface. In our issue of April 15 Mr. J. Parke Channing gave a brief resumé of the development of steam-shovels for this work on the iron ore ranges of the Lake Superior region. As our readers know, an extension of their use to the mining of copper ores has been made by the Utah Copper Company and the Nevada Consolidated Copper Company. Through the courtesy of Mr. C. B. Lakenan, general manager of the latter company, we have been furnished with some recent records made in the Copper Flat pit at Ely, where, during the June the No. 6 shovel handled 74,600 cubic yards of stripping, approximately 150,000 tons. The cost of the work averages 15 cents per dry ton of ore (average moisture 6 per cent) or 14 cents per cubic yard of stripping. Slightly lower costs are attained in summer when the digging is a little easier, and the delays are fewer. Similar work is being done in the Bingham pit of the Utah Copper Company, where with 18 or 19 shovels at work, ore and overburden are being handled at the rate of 40,000 tons per day, or roughly, 30 tons per minute. During the quarter ended March 31 the cost of dry excavation in the central zone of the Canal was given as 57 cents per cubic yard. In the absence of itemized costs, close comparisons are impossible, but it is evident that our friends in Nevada and Utah are making records in this work.

To the engineer of imagination the scene at Bingham at night, with the shovels at work beneath the glare of the searchlights placed upon the hills opposite, is dramatic in the extreme, indeed, the whole work which Mr. D. C. Jackling and his associates have carried on is a striking example of creative imagination applied to engineering work. In a later issue we propose to discuss more at length some of the problems met in carrying on mining and milling on so huge a scale.

San Francisco Meeting of the A. I. M. E.

Plans for the meeting of the American Institute of Mining Engineers in San Francisco October 10 to 17 have been announced in the Bulletin of the Institute and in a special circular mailed this week to California members by the local committee. The opening session will be held at the St. Francis Hotel, official headquarters, Tuesday afternoon, October 10, and will be followed by other sessions on Wednesday and Thursday mornings and perhaps in the evenings. Under the chairmanship of Mr. F. W. Bradley, who has charge of the matter, particular emphasis is being placed upon the sessions, since there has been in some quarters too much of a disposition to regard the excursions as the most important feature of Institute meetings. One session will be especially devoted to the consideration of problems of cyanidation, and a number of important papers are already in hand. On Thursday afternoon, October 12, a special train of Pullman and dining cars, in charge of the local committee on excursions, of which Mr. E. H. Benjamin is chairman, will take the party to Bakersfield, arriving early Friday morning, for a visit to the various oilfields. On Friday night, October 13, the party will proceed by train to the heart of the gold-dredging district, near Folsom, spending Saturday morning, October 14, in visits to the gold dredges and the great rock-crushing plant of the Natomas Consolidated Company. On Saturday afternoon, through the courtesy of Hon. Hiram Johnson, Governor of California, a public reception will be held in the State Capitol, Sacramento. Later in the evening the train will transport the party through the Napa and Sonoma valleys, arriving at the Bohemian Club amphitheatre on Sunday morning, October 15, where a barbecue luncheon will be held. The day will be spent in this delightful grove and an orchestral concert will be given on the great natural stage where the plays of this famous Club are presented. On Sunday evening the party will return to San Francisco, and devote Monday, October 16, to rest and preparation for the Japanese delegation, and possibly to a few local excursions. Suitable provision will be made for entertainment of the ladies accompanying the members, but exact details regarding this have not yet been announced.

In order to complete arrangements it is necessary that the committee should know at the earliest possible moment for how many to make provision. The cost of the excursions, including railway and Pullman fares and meals, will be $35 per individual. It is proposed to offer this excursion free to members of the Institute outside the State, but those living within California and taking part will be asked to pay their *pro rata*. Members residing in California, particularly, are asked to notify the chairman of the local committee, Mr. W. C. Ralston, whether they expect to take part in the excursions. They are also requested to contribute to the general expense of the meeting whatever they may be able, and to do so promptly. A large and interesting meeting is assured, but papers, money, and personal service are all needed to make the session entirely successful.

Chicago and the Mining Congress

The meeting of the American Mining Congress at Chicago September 26 to 29 will probably be of more than usual importance and interest. According to the program announced, a large measure of attention is to be devoted to Western land problems and especially to those relating to the public coal lands. No topic more important could have been selected and the discussion should result in something definite and practical. Chicago is a great coal centre and attending the Congress will be an unusual number of men who know the coal business in all its details. There will also be a liberal attendance of Government officials and leaders of Eastern thought. Mr. Walter Fisher, who as Secretary of the Interior is sure to have large influence on the future policy of the Government, will be present, as will, probably, the President. The West will be well represented, for the American Mining Congress remains dominantly Western in membership and spirit.

A curious situation has arisen, one in which the East, the staid conservative East, is moving for a change, while the West, the harum-scarum radical West, is resisting. That the land laws of the United States are archaic and much in need of revision is generally recognized. The East, having the votes, is likely to control results if it be united and determined. At present it is fair to say that, without perhaps full information on the subject, the East favors the application of some form of leasing system to the remaining coal-lands. The West, with full knowledge of the methods under which development has so far taken place, but with little experience in leasing, opposes. We do not propose to discuss the matter at this time, but we would point out that Chicago is a peculiarly favorable place, and the meeting of the American Mining Congress a peculiarly favorable time, for a full investigation of the matter. At Los Angeles last year the meeting was dominated by men opposed to any leasing system. It is but fair to say that they were, in the main, entirely unexperienced with such systems as have been developed on private lands in the East, on State lands in Colorado and Montana, and on public lands generally in the British Dominions. There were as a result numerous misstatements of fact, and the ignorance exhibited by advocates of the present system was quite as dense as any that may properly be imputed to 'uninformed Easterners.' It is to be hoped that a more valuable discussion may take place at Chicago.

At bottom, this is a business matter. The great national resources must be both developed and conserved. The present system has numerous admitted faults and any proposed substitute may be reasonably expected to show others. No system of administration of the public lands will prove beyond criticism. The essential thing is to make a wise choice, and one which is not irrevocable. That experience is a 'dear teacher' is true, but the experience of others may be cheaply converted to our own uses. It is desirable to have fewer arguments about what will or may happen, and a more careful consideration of what does actually happen under different systems of administration. Go then to Chicago and speak out of the fullness of your experience, and then keep still and learn from other men's experience.

The Oil Industry and Public Lands in California

By William Forstner

All present indications tend to the conclusion that the oil-bearing public lands in California, temporarily withdrawn from entry, will at some time in the future be again made accessible to the public under a leasing system, and that the present method of acquiring those lands under the placer law will not be reintroduced. It is useless in the present state of public mind to argue that the introduction of a leasing system will not prove beneficial to the development of the oil industry. Arguments as to the inconsistency of a governmental regulation which allows one man to obtain a patent on 160 acres of government land, carrying gold-bearing gravel, or any other mineral, upon the condition that he shall have spent $500 in improvements on that ground, and refuses to grant a patent to another man on 160 acres of government land carrying mineral oils, for the discovery of which he must have spent much larger sums of money, only granting him a lease on that land are interesting, but likely to be futile. It is apparent that unless an unexpected change in the mind of the authorities at Washington takes place, it will be useless to attempt to obtain a more favorable settlement of this question.

It is contended that the leasing system is worked to advantage on lands belonging to private individuals; that it is also used in other countries; but it must be conceded that in both these cases the conditions are different. The same may be said in regard to the proposal to modify the present coal-land law into a leasing system. The conditions under which oil discoveries are made are essentially different from those governing discovery of other minerals. The discovery of those minerals is generally brought about by surface indications at some not distant point; the discovery of oil is based on outcrops of formations at a considerable distance from the point of actual development, and occurring under such conditions that it is impossible to determine beforehand whether at the point of discovery the oil will be found in commercial quantities or not; nor is it possible to even approximate the cost to be incurred in this discovery. With coal lands the conditions are different; usually the outcrops of the coal beds can be traced and a general opinion as to their thickness and that of the intervening strata can be gained from surface indications. The underground conditions can in most cases be ascertained by diamond-drilling, at a relatively low cost, and in this manner the risks in developing a new territory are greatly reduced.

I have before me a map on which the different withdrawals and restorations to entry on the west side of the San Joaquin valley from Coalinga to Sunset are designated. In this territory the Government has had a number of its best geologists for a considerable length of time, and yet some of the withdrawals have been subsequent to the discovery of oil in the territory so withdrawn, and other discoveries have been made in territory not as yet withdrawn; while in large withdrawn tracts development done has as yet failed to prove the existence of commercially valuable oil. I do not wish to have this statement understood in any way to be a criticism of the government geologists, it simply enforces my argument that the existence of commercially available oil deposits can only be proved by actual drilling. The drilling of oil wells in a new territory is expensive, and can only be undertaken by men or by companies commanding considerable capital. It is true that the original discoveries of oil have in most cases been made by men of small means, but here the element of chance has played a considerable part. When the men who drilled the first well in the Coalinga oilfields, at Oil City, struck the oil-bearing sand they had arrived at the limit of their resources, and if the territory had been somewhat deeper they would have had to abandon their undertaking. This is only one instance out of many. When men have the energy to take such chances it is only fair that they should receive ample returns. I will go farther and state that such men will only take those chances when they are assured of such returns in case of success; and if regulations be made which will hamper them in getting those returns in case of success, they will apply their energy elsewhere.

The leases taken in California on oil lands belonging to private individuals vary according to the conditions of the district. In proved or nearly proved territory these leases are generally for 20 years, usually with a right of an extension, at least as far as the producing wells are concerned, until production is exhausted. The usual consideration is a royalty of from one-eight to one-fourth of the production; in doubtful and unproved territory those leases usually carry the privilege of purchase within a certain lapse of time after discovery at a price far below the value of the land when proved to be oil-bearing. Most of the owners of private lands are more or less in touch with the oil business; they are to a certain extent acquainted with the many difficulties with which the operator has to contend, and in these leases they leave him entirely free in his mode of operation, only stipulating for a moderate rate of development. This may have some disadvantages, especially in the matter of allowing water to enter the oil strata through the carelessness of the operator, but as this endangers the neighboring properties, the community interests in a district under development tend toward a protection.

One of the greatest objections to the system of leasing by the Government lies in the fact that those leases will be subject to regulations made by the department in Washington, and thus terms will be settled by officials who have no actual experience with the details of the operation of oil properties. It is the experience all over the world that government bureaus always have the tendency to expand their influence and regulate from the seat of the government the minutest details of all matters coming within their supervision. If a leasing system for the government lands is to be introduced, the oil-men will have to use their best efforts to have the regulations drawn in such a manner as to prevent any undue interference with the operations of the leased lands by the authorities in Washington; to obtain this result will demand all their efforts, and even then I doubt whether they will entirely succeed. That the terms upon which leases will be granted are of the greatest importance will be readily recognized by those acquainted with the oil business, but it is doubtful whether this will be the case with the authorities in Washington, and certainly not with the members of Congress, where the matter will finally have to be settled. Unfortunately the general public has the mistaken idea that the development of an oil property is a very simple undertaking, 'just drilling a hole in the ground.' All the difficulties encountered in drilling that 'hole' and the great expense incidental to the taking care of the product are seldom, if ever, brought to the attention of the public. The oil-men will have for their own protection to begin a campaign of education.

Another difficulty which will be encountered in framing a law adequate to the situation is the present condition of the public mind in regard to corporations. During the last years the public has been so constantly impressed by writers in the public prints with the evils and abuses of the large corporations, that it has got into a state of hysterics on this subject, and at the present time no sane and businesslike appreciation of all the intricate conditions pertaining to its consideration can be expected. Everyone connected with the control of a large corporation is considered by the public at large as tainted with dishonesty, and every act of such corporation to protect the interests of its stockholders as an act of monopolistic oppression. Corporations have made mistakes and will make mistakes in the future, so do all of us individually, but the benefit they have brought to the development of the resources of the country overshadows their mistakes a hundred times. The enormous expansion of the industries, business of the country during the last 25 years is almost entirely due to the activity of the large aggregations of capital, working through the instrumentality of the corporations. This is not a local phenomenon, but world-wide. Large industrial establishments can produce and distribute their product cheaper than a number of small producers, having in the aggregate the same output, and this economic fact underlies at the present time the industrial business policy of the entire world. This is the reason that in all countries, except our own, the governments are friendly to the combination of enterprises working in the same line of business. The United States has become in the latter years an exporter of manufactured articles; in other words in order to keep up the present rate of production, which is larger than our local consumption, this country must compete in the world market with all other manufacturing countries. Is it then rational to destroy, or at least to seriously hamper the only instruments through which this competition can be successfully carried on? The result would be that power to compete in the world market would be crippled to such an extent that production would have to be restricted to the local power of absorption of manufactured products; which would mean a restriction of production, and a further decline of consumption. Another inevitable result of the present tendency to antagonize capital must be well considered. Capital can find employment and is offered remunerative investments all over the world. If then the United States pursues the policy of persistently harassing it, the inevitable result will be that, not only foreign capital will retire its investments in this country, but that local capital will seek investments in those countries which adopt a more friendly attitude.

This subject is germain to the question here discussed, because the oil business, for its proper development, requires the use of large capital. The following examples will prove this contention. In the south Coalinga district work was begun years ago, when ten wells were drilled in the Kreyenhagen field and three in the northwest part of the district. In 1909 work was again resumed, and since then 19 wells have been drilled. Out of this number only the two shallow wells of the Berkeley-Coalinga Oil Co. are producing. Of these 19 wells, three are over 400 ft. deep, and one of these, costing about $100,000, has been abandoned. Another well, after having been drilled to a depth of 2400 ft., had to be turned into a water well, and a new well drilled which is at present 3450 ft. deep. I believe I am not far wrong in estimating that close to $1,000,000 has been expended in this district without, as yet, any financial return. In the Kettleman Hills, certainly $300,000 has been spent without a discovery of oil being made. In the Elk Hills at least $1,000,000 has been expended in the last two years, and up to date only one well has been brought in, with a daily output of 160 bbl. and a depth of over 4000 ft. To market this oil a pipe-line more than 7 miles in length would have to be laid. The oil and gas discovery in the Buena Vista Hills was made by the Honolulu Consolidated Oil Co. This company has been working three years in this territory; has spent $2,500,000; some of its wells have cost over $80,000 to drill not including the general operating expenses, as building of roads, establishing of machine-shops, etc. The present output in natural gas and oil is not sufficient to cover the operating and development expenses.

Similar cases could be cited from each district in California, but the above will be sufficient to justify my assertion, that for the interest of the oil industry in this State it is of the greatest importance that nothing be done to deter the investment of capital in its development. It might be argued that, as we have at the present moment an overproduction, there is no need for the development of new territory, and that in the territory already proved, the small producer can take care of the situation. The present surplus of the production over consumption is the result of extraordinary conditions in the past. If the production and consumption of the months of April, May, and June, 1910 be compared with those of the same months of 1911, the following appears:

Year	Production, bbl.	Increase, per cent.	Consumption, bbl.	Increase, per cent.
1910	20,702,880		16,176,211	
1911	20,746,881	0.2	18,144,286	12.2

These figures indicate that before long the surplus of production over consumption will disappear, unless an unexpected extraordinary increase in the production should occur. The gradual decrease in production of the existing wells in the productive area will counterbalance the increase resulting from the new wells brought in within those areas, and the production would soon become stationary unless the development of new territories did not enlarge the productive area of the State.

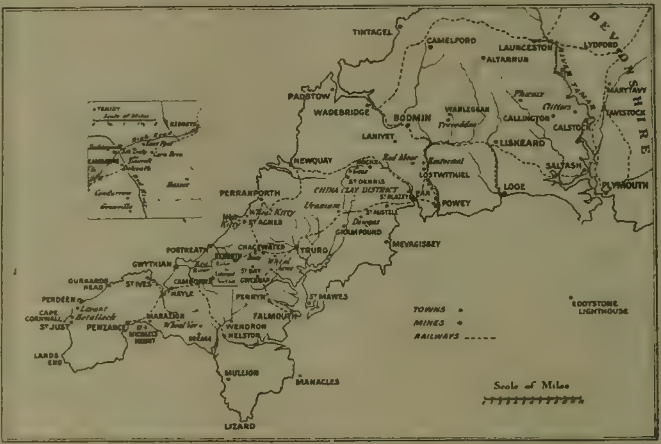
In the interest of the oil industry it is, then, of the utmost importance that in the new legislation regarding the future development of the Government lands within possible oil-bearing districts, no stipulations be enacted which will tend to deter capital from readily investing in this industrial field. This feature must be borne in mind by the men interested in the oil industry, especially when George Otis Smith, Director of the U. S. Geological Survey, an official who will undoubtedly have a large influence on the drafting of the terms whereunder the Government leases will be granted, emphasizes that those leases should "secure the prohibition of too large holdings of Government leases by big companies," and further states that they shall "insure against excessive charges to consumer". I believe that a small lease-holder should be at liberty to transfer his lease to such parties and under such conditions as are at the time the most advantageous to him. He has given his time, his energy, and his money, and he is entitled to derive therefrom the greatest possible benefit, without interference from the party, in this instance the Government, who has profited by his efforts. To have the Government supervise the returns he may receive from his product is certainly unsound from an economic standpoint. To demand that the man who has invested his time and money in a risky undertaking shall be limited in his profits in the case of exceptionally favorable circumstances, is an economic mistake, unless the Government agrees to pay him a certain minimum price for his output, as the Canadian Government undertakes to do without specifying a maximum price. It may be to the ultimate benefit of the oil industry in California that the regulation of this matter be delayed for a time, until public opinion be restored to a frame of mind which will allow a dispassionate and business-like discussion of the different conditions which demand consideration in the final settlements of this question, even while recognizing the great harm done by the present muddle in which this question finds itself.

SUBSTANTIAL progress has been made during the last twelve months with the construction and equipment of the Benguella railway, Portuguese West Africa, and traffic is now running up to the railhead, 200 miles from the sea. This railway runs from the port of Lobito, on the west coast of Africa, eastward through Portuguese Angola toward the Belgian Congo, and it is proposed ultimately to extend it to join the Rhodesia railways and the Cape-to-Cairo line. The portion from 123 miles to 200 miles was completed in October last. A contract has been arranged for the construction and equipment of a further section extending up to 223 miles, and the surveys for the line up to Mutota, 559 miles from Lobito, are to be completed by the end of June. The total distance from Lobito to the Congo frontier is estimated at about 807 miles. The gauge is 3 ft. 6 in. Lobito possesses one of the finest natural harbors in Africa, with a substantial timber jetty that is capable of accommodating the largest steamers running to South Africa.—*Railway Age Gazette.*

THE VOLUME of the ocean is 302,000,000 cubic miles.

An Engineer's Pilgrimage to Cornwall

A visit to Cornwall bears to the mining engineer much of the significance that a journey to Italy and Greece does to an artist. It was, then, with lively anticipations that one morning shortly before Christmas, I set out on the Penzance Express from Paddington in company with Mr. Fern, the secretary of the London and West Country Chamber of Mines. Having specified the time and place, it is perhaps unnecessary to add that the day was chill and overcast, with lowering clouds that from time to time proved that their threat of rain was not merely an empty one. As we followed the Thames, near Maidenhead, the swollen river was seen to have invaded the fields, and in places even ventured to lap the edges of the railway embankment. There is no stop before reaching Plymouth, and the first sight of that wonderful harbor makes the preceding events of the journey seem of little import. At its mouth the Tamar river widens, forming Plymouth south and the great basin of the Hamoaze, four miles long, which together with the estuary of the Plyne, called the Catwater, form the most beautiful of English harbors. The Eddystone lighthouse was lost in the mists a dozen miles off shore, but the citadel and the warships at anchor showed the naval importance of this famous town, from which the Pilgrim Fathers in 1620 set out for the New World. And as one surveys the sweeps of the harbor, the curves of the hills, and revels in the soft tones which the mists of Devon, Cornwall, give to the landscape, a better understanding of Turner's genius is obtained. The train glides over the Royal Albert bridge, the most striking of the engineering works of the celebrated Brunel, and we are in Cornwall. The country becomes more mountainous and is everywhere a vivid green. An American is surprised to see how little active cultivation is going on. There are flocks of cattle, to be sure, but few ploughed fields are seen, and a clearer perception comes of how marked is the effect upon industrial life of a social system that permits the holding of large tracts of land as private parks and game preserves.



GRENVILLE, SHOWING CORNISH STAMPS.

GRENVILLE, SHOWING STYLE OF CONSTRUCTION.

Between Plymouth and Truro the train skirts the border of St. Austell bay, the track occupying the narrow beach between the foot of the cliff and the sea's edge. When there is a storm the spray and spindrift must make this portion of the journey seem almost like a ride with Neptune. At Truro it is necessary to change to the local train which stops at Redruth, where I had planned to stay. This typical Cornish town reminded me strongly of towns of the same size in the Lake Superior district, but Tabbs hotel was as unlike anything to be found in America as was the clotted cream served me to eat upon my dessert. Continental cities are something of a disappointment, they are so unlike preconceived ideas of them, but England is so astonishingly and pleasingly English that it is a delight. Then, too, blood is thicker than water, and though the disputes between relatives are often more acrimonious than those with strangers, kinship holds, and the American feels in England a sense of at-homeness that is lacking on the Continent.

Tin mines can be found throughout Cornwall and the adjacent portion of Devonshire, but many of the largest and most famous are between Redruth and Camborne, skirting the northern border of the great granite batholith which has shattered and metamorphosed the slates about its borders, giving rise to veins which pass from the granite into the slate and are most strongly developed near the contact, though many veins occur wholly in the slate or in the granite. The valuable minerals are 'tinstone' or cassiterite, wolframite, and metallic sulphides, chiefly of iron, copper, and arsenic. Formerly the mining of copper in Cornwall was an important industry, but now it is a thing of the past; tin, tungsten, and arsenic, the two latter by-products of tin-production, are now the only metals of much importance in Cornish industry. In ancient days tin was produced from the stream beds and copper from shallow underground workings, but now the streams, except the Red river, into which the tailing from the mills discharges, are largely worked out, while the copper veins have grown too poor in depth to permit of deep mining. Deep mining of the tin veins is now most important, though the others still persist in places, and an attempt has even been made recently to dredge the stream deposits, but without financial success. This leads naturally to another significant feature of Cornish mining that comes as a surprise to the visitor; the number of mines which continue working, though not a financial success. This takes us into a critical examination of the Cornish social system, a maze where even the incautious would fear to tread. Generalizations upon any intricate subject are necessarily incomplete and inaccurate, but it does not follow that they are not worth while, for they permit the conveying of general impressions in a way otherwise impossible. At the risk, then, of destructive criticism, I will venture to give the impressions formed during so brief a visit.

Cornwall is an old mining district, therefore an intricate network of relationships has gradually formed and the tracing of the threads becomes almost impossible. When a eucalyptus tree grows, the old bark cracks off and falls away, leaving the trunk free to expand, but a social system appears to lack so useful a development, and therefore revolutions and social upheavals bring about the catastrophic changes that uniform change is unable to effect. Industry is likewise restricted in its growth, and the Cornish mining industry of the present is hampered by much that persists from former times. When a business has outgrown its building and equipment, we tear them down, sell them for scrap, and erect new machinery in more commodious quarters. But an outgrown superintendent or manager has no value as scrap, nor may he be so ruthlessly torn down. Then, too, it is often possible to continue to make small profits with antiquated equipment that is already amortized, where the increased saving made by new and better machinery would not equal the increased interest and amortization charges. This serves to explain methods of work that appear peculiar to the uninitiated, but throws no light on the question why mines should continue to work at an annual loss, as may be seen to be true by referring to table I. But this is equally explainable; the principal shareholders in the mines are local landlords and business men, who derive their income from rents, or the profits of other business. To close down a mine when its yearly profits are not a fair interest on the invested capital, would seem a wise proceeding, but when we remember that on the loss of their employment the workmen would emigrate, producing a loss in rents and profits many times the loss resulting from mining operations, the folly of such a course of action becomes evident. What at first sight seems unwise proves, on closer examination, to be very good business, and this is likely to prove true of many phases of Cornish mining, for it must be remembered that the peculiar features of a system of working may be perceived at a glance, but the governing causes that have produced them are not often so quickly discerned.

So many descriptions and discussions of Cornish mines and their methods of work have appeared that it is scarce worth while to attempt a detailed description of the few I was able to see, and I will content myself with giving bits of description that may prove of interest.

DOLCOATH, SHOWING 'RAG-FRAMES' AND 'STRIPS.'

One of the best known Cornish mines is Dolcoath, where the situation is easily reviewed. To the east, in the Red river valley, are the small, crooked, old-time shafts that are still used to a certain extent; to the west, in the hill, are ordinary shafts from which the production is now obtained, while to the south, beyond the railroad, is the new 3000-ft. shaft, 17½ ft. in diameter, and lined with 9 in. of brick. It is equipped with plunger-pumps, belt-driven from an electric motor, and when this shaft is fully in use, all the hoisting and pumping will be concentrated at this point, replacing the old 'Cornish pitwork.' Objections to Cornish pumps are: (1) they cannot be speeded above 6 to 8 strokes per minute without shaking to pieces; (2) the leakage-water dropping down the shaft interferes with its use as an upcast; (3) they take up too much room and make the shaft too unpleasant to work in. The plant on the surface shows equally striking contrasts. In one mill the old Cornish pumps, with their 660-lb. cast-iron shoes cast directly on a square wrought-iron stem, are pounding away. In place of the modern cam there are pegs on the shaft, and, since the stamps cannot turn, they wear rapidly. After a while they are turned around, to make the wear even, but the decrease in weight as they wear away makes the stamp-duty low. As these old stamp-mills wear out they are gradually being replaced by either the ordinary California stamps, or else the Holman pneumatic stamp. These latter I saw at work in the mill of the East Pool and Agar United, near Carn Brea. They are quadruple-discharge single stamps of a capacity of 24 to 28 tons per day with a power consumption of 20 hp. The stamp drops 140 to 180 times per minute. The shoes last 9 days, the dies 45 days, and the suspension trunnions about two years. The cost of crushing by the three different methods is analyzed in the following table (II), kindly furnished by Harold Fern.

TABLE I

RESULT OF WORKING FIVE OF THE LARGEST MINES IN CAMBORNE AND REDRUTH DISTRICT DURING 1909.

	Dolcoath, Ltd.	Carn Brea & Tincroft Mines, Ltd.	South Crofty, Ltd.	Basset Mines, Ltd.	Grenville United Mines, Ltd.	Total five Mines.

A striking feature of Cornish mines is the peculiar methods followed in the transaction of business and the keeping of accounts. The ancient charters, by which the tinners are exempt from the jurisdiction of any court besides the Stannary Courts, except in cases affecting land life or limit, and the curious practice of 'tin ticketing' are of great interest, but they have been often described and more space cannot be accorded them here. The 'cost-book' system of account keeping is typically Cornish; those who are interested in the details of its working should refer to the extended discussion given in the interesting paper, 'The Cost-book Company,' by Harold Fern, but a crude statement of it would be that it is a partnership, where all the receipts and expenses are put down in a book and at the end of the year the profit or loss is shared proportionately. The disadvantages of this are obvious, and the companies are now nearly all being converted into limited liability companies. But even in these the methods of keeping accounts are such that it is usually impossible to analyze the working costs. But two of the mines do this, and in the table below is given a summary of their working costs. The most striking feature of these is the high cost per ton for pumping; this is one of the burdens of mining in Cornwall, and the many tons of water to be raised daily from deep shafts form a strong argument for the use of the Cornish engine, with its large number of foot-pounds of useful work per ton of coal.

Returning to London and reflecting on what I had seen, I was irresistably led to the conclusion that great and important as the output of mineral wealth of Cornwall has been, it is far outranked in worth and importance by her greatest contribution to civilization, the Cornish miner and engineer. The names of those who have gone out from Cornwall to be leaders in the development of mining and metallurgy are known the world around. I had seen Redruth and Camborne, Dolcoath, East Pool, Carn Brea & Tincroft, I had lunched with the veteran, J. H. Collins, whose sons have in the far corners of the earth upheld the reputation of the Cornish engineer, and I had shaken hands with Richard Pearce and heard him tell of the days when metallurgical history was being made in Colorado; I had finished my pilgrimage.

Better Prospecting at Joplin

By Otto Ruhl

For many years mine operators and engineers have recognized the need for better prospecting in the Joplin district than that afforded by churn-drilling, but trials of diamond-drills failed to encourage, and so makeshift methods were accepted. As the district developed year by year, as the investment for each mine grew from a few hundreds to upward of $30,000, the need for more certainty before sinking a shaft became insistent and the search for a drill that would give accurate results began in earnest. Recently core-drilling has been successfully done by the Oronogo Circle Mining Co., operating a mine at Oronogo, Missouri, eight miles northeast of Joplin. In an effort to demonstrate the extent and character of the ground below the 240-ft. level, churn-drilling was first attempted. Three holes were drilled with an ordinary churn-drill starting in the mine. The machine was lowered into the ground, and for the first time in the district's history drilling was done underground. This effected a saving of 240 ft. over work from the surface. The results were highly satisfactory in showing rich zinc down to the 330-ft. level, but the investment necessary to open these deeper runs, together with the known inaccuracy of the churn-drill, caused the company to hesitate about undertaking the work until the supposed discovery should be confirmed. It was at this stage of the proceedings that a decision to try out a core-drill was made.

The work of selecting a new machine was approached with considerable care. So far as could be ascertained, only one successful drill-hole had ever been put down in this district by a diamond-drill. This was done by the Edgar Zinc Co. on its Homestead tract at Carterville. But it must be remarked that no more were attempted, because of the excessive cost. Diamonds were costly and the number lost by the drilling into crevices in flint were too many to encourage further trials of this machine. Trials at other points in the district were even more discouraging, and the diamond-drill was generally condemned as impractical and too costly. Shot-drills had also been tried. These, while not successful in the full sense of the term, did make a better record, both as to cost and performance. They then offered the better prospect, and the company ordered a Davis-Calyx class F-1 shot-drill, from the Ingersoll-Rand Co. To insure a fair trial, an expert drillman was sent to erect the machine, start the drilling, and train a crew of Joplin men.

Due, perhaps, both to the expert operator and the determination of the company management that everything possible should be done to insure the success of the machine, the drill was a success from the start, not only from the standpoint of speed, but also, after the first hole, from that of cost. As the crew of Joplin drillmen became more familiar with the machine, better speed and better results were obtained. Even the first hole showed an average of 4 ft. per day, while a maximum of 8 ft. was attained on several days. The maximum increased to 13 ft. on the second hole, and to 17 ft. on subsequent holes. The speed of drilling, however, is directly proportional to the hardness of the rock, while other factors entering into the speed are the number of crevices and the frequency of taking out the cores.

In hard rock, of which the 'black flint' is by far the hardest, the drill could make but slow headway. Three feet per day of eight hours in this formation was considered rapid progress, while ordinary limestone was easily penetrated. The ordinary white and blue flint of intermediate hardness showed an intermediate rate of drilling. The scale of rapidity was from limestone, white flint, blue flint, to 'black flint'. Crevices proved troublesome from the standpoint of speed, only. When one was found it was only necessary to fill it with quick-setting cement, after which drilling could be resumed. Waiting for the cement to set was the factor that consumed time. This time could be utilized in taking out the accumulated core, but other than this and perhaps the few little adjustments of the machine, the time loss was heavy.

The taking of the cores from the core barrel had to be frequent enough to prevent any great abrasion. The hardness of the flint as contrasted with the softness of the zinc blende created a condition that necessitated care. If a core broke just at the junction of the flint with the zincblende, the two sections of core revolving upon each other had a tendency to rapidly pulverize the blende; thus vitiating the record. Necessarily, then, when the drilling was in an ore deposit, the core had to be drawn often, and it is estimated that this occupies fully one-third of the time. The character of the rock drilled determined the character of the core. The six holes put down show practically the same sequence of interbedded limestone and various colored flints or cherts. Many crevices were encountered, some of them entirely open, others partly filled with zincblende. Such crevices usually resulted in the core being broken. The partings were not always horizontal, but varied from horizontal to an angle of over 45° from horizontal. Cores 30 in. long were taken out. From this they ranged downward to 2 in. The average was 6 to 8 in. in length. The zincblende occurred in pockets or seams running from 1 to 6 in. in thickness and also disseminated in the flint and limestone. The cores were 3¼ in. in diameter and came from a hole 4¼ in. in diameter. They gave a good sample of the ore, its gangue matter, and information regarding the manner of its association. From the records so far obtained, the amount of disseminated ore in both flint and limestone at this point is considerable, and gives an insight into what may be expected when the deeper levels come to be worked at other points in the field.

The cores are stored in boxes especially constructed to hold 10 ft. of core. The boxes are 5 ft. long and contain two 5-ft. lengths. The depth is indicated on the cores by proper tags, each separate piece of core being so tagged. The cores containing ore are sawed in two vertically, one-half being ground for a sample for assaying, leaving the other half to complete the core record. This system was employed for a few of the holes, while with the remainder the cores were broken to ½ and ¾-in. sizes, then quartered, and a sample taken, which was assayed, the remainder being returned to the core box.

The cost of drilling with this machine to a depth of 90 ft., as figured from the records of the Oronogo Circle Co., was $1.25 to $1.30 per foot. This cost includes the items of labor 95c. per foot, power and repairs 10c. to 15c., and steel shot 15c. per foot. These cost items should be analyzed to be fully understood. In the first place, only skilled workmen of the highest order were employed in the operation of the machine. The ordinary churn-drill can be operated with cheaper labor, first because it does not require such skill, and second because of the greater number of men familiar with churn-drill work. In the second place, it should be kept in mind that these costs are based upon work which was largely experimental, as the records of improvement in the drilling showed. It is believed that with the present trained crew of workmen the cost can be reduced to $1.10 to $1.15 per foot on a similar amount of work under similar conditions. This would compare with 80c. to 90c. per foot for churn-drilling. In the core-drill work the record or log obtained would be absolutely accurate and knowledge of a concrete character would be obtained from it, while in the churn-drill log inaccuracy would be certain, and the knowledge gained from the log would be meagre.

This record of performance has been watched by a number of the most progressive operators, and already plans for core-drilling in other portions of the field are in progress. For the present these plans involve work in a limited field; the Webb City sheet-ground area, the West Joplin disseminated field, and the deeper levels of disseminated ore in limestone, developed at Cave Springs and in North Empire. It is apparent immediately that the 'soft ground' deposits are outside the limit of this machine's work, and these will always be developed by the churn-drilling. But the field for the deeper drilling in hard ground is large, and, judged by the development of the past seven years, will become even more important. It is just this field that has the narrowest limits for successful operation and in which the largest numbers of failures have been recorded. The one remedy agreed upon is that such prospecting must be adopted as will give absolute and reliable information before expending the money necessary for developments. Core-drilling seems to promise such a remedy.

A few instances of the inaccuracies of churn-drilling will suffice to show the possibilities for the core-drill work in the Joplin district. In the drilling with a churn-drill the sample may be too rich, or the reverse. One is just as likely to have a good drill record upon a poor property, and a poor drill record upon a good property, as to have the records give correct data. In sheet-ground a drill-hole put down may show a thick stratum of zincblende in shelly flint. The softness of the blende causes it to be broken quite a distance from the outer edge of the hole and to salt the sample. Even where cased off, the impact of the falling steel will jar loose considerable blende which, falling down through the crevices, salts the sample, and an inaccurate log results. There are numerous instances of such holes in the north Webb City district. The directly opposite condition sometimes results when the drill enters ore in a running watercourse, the cuttings being washed away to such an extent that the record may be bad while the ground is really good. Still another case where churn-drilling proves inadequate is in disseminated deposits in limestone. Here the impact of the drill steel reduces the rock to impalpable powder, and the softness of the limestone, together with the likelihood of the ingress of surface water or water from an upper stratum, makes it highly probable that a great deal of the limestone is taken into solution or held in such finely comminuted particles that any samples taken give too rich a sample and the prospector is misled.

Other reasons now operating against the churn-drill in the Joplin district are the loose methods employed, speed being the main idea of the contracting driller. Most of the work here is done by contract. Inadequate cleaning of the hole, improper casing, or none at all, improper sampling, too much drilling between clean-outs, and finally, the inability to preserve the samples so that the geological formations may be recognized at all times, make churn-drilling valueless except as a mere indicator of the presence or absence of ore upon a tract of land. This is being recognized quite generally, and, while all operators agree as to the rapidity of churn-drilling, its inaccuracy offsets this advantage.

It seems possible to make use of this good feature of the churn-drill and combine with it the good features of the core-drill. If this can be done, and it certainly appears feasible from the work so far accomplished, the cost of drilling will not be greatly increased over the prevailing rate, and at the same time accurate records of the ore deposits can be secured. By utilizing the churn-drill down to an ore deposit and then casing the hole, the core-drill could be introduced to take out a core of the ore deposit, and, as the deposit is usually but a few feet thick as compared with the amount of barren rock penetrated to get to it, the proportion of high-cost drilling to the low-cost drilling will be small. For example, consider a hole 180 ft. deep to the ore deposit and with a body of 20 ft. of ore. The churn-drilling at 90c. will amount to $162, the core-drilling of 20 ft. at $1.25, to $25; a total of $187 for the 200 ft., or 94c. per foot. The extra cost is negligible as compared with the greater reliability of the prospecting. This has so appealed to mine operators that within the year several such prospecting campaigns will be put under way. One is scheduled to begin in the north Webb City field, and another west of Joplin in the disseminated-ore field. In southeastern Missouri diamond-drills have long been extensively used, as also in the Lake Superior copper and iron districts. In the latter churn-drills and diamond-drills are used together. In zinc districts churn-drills only have generally been used.

Potash Investigation

An investigation into possible sources of potash salts in the United States is being made this year by the United States Geological Survey under an appropriation by Congress of $20,000 for the current year. One of the possible sources from which potash may be derived is in association with saline deposits left by drying up of large bodies of salty waters, such as are known to have existed at one time in many of the now desert areas of southwest Oregon, Nevada, southeast California, in Utah, and elsewhere. It is hoped that by testing these saline deposits some may be found sufficiently rich in potash to have a commercial value, and that there may even be located some large and important deposits.

As a part of this work the Survey will soon fit up a temporary laboratory at Fallon, Nevada, for the purpose of testing samples of salines from the Great Basin or desert areas. Samples of such alkaline salts will be tested at this laboratory free of charge if a definite statement of the locality from which they were obtained be sent with the samples. The location should be given by section, township, and range, if possible, otherwise by distance and direction from the nearest post-office or settlement. Samples should be addressed to Hoyt S. Gale, United States Geological Survey, Fallon, Nev. Upon receipt of a request, small sample sacks for sending the material by mail will be forwarded from the above address. If so requested at the time that a sample is submitted for test, the accompanying information concerning the locality of the deposit will be treated as confidential; and the evidence thus obtained is not to be used for the purpose of making land withdrawals.

Coal and Oil in California

California's production of coal in 1910 was 11,164 short tons, with a spot value of $18,336, according to E. W. Parker, of the United States Geological Survey. In 1909 California showed the largest percentage of increase among the coal-producing States. In 1910 it showed the largest percentage of decrease. Both changes were due to fluctuations in the operations of the Stone Canyon Con. Coal Co., in Monterey county. For two years preceding 1909 this company had expended large amounts of money in developing its property and in building a 25-mile railroad to connect its mine with the Southern Pacific railroad. Unfortunately, unforeseen difficulties were encountered, and one misfortune followed another until the resources of the company were exhausted, and, as it was unable to procure additional capital, a receiver was appointed, and work was suspended in October 1909. In the nine months from January to September of that year the Stone Canyon mines had produced 75% of the State's output for the entire year. No coal was produced at this mine in 1910. All of the coal produced in 1910 came from Amador and Riverside counties, principally from the Ione mine in Amador county. This coal is lignite. The Stone Canyon coal is a non-coking bituminous coal of good quality and should make an excellent domestic fuel. It stands exposure and with favorable freight rates would compete successfully with foreign coals in the markets of San Francisco and other cities of the State.

The small production of coal in California is offset by the enormous increase in the production of petroleum, most of which is used for fuel. The oil produced in California in 1910 aggregated between 65,000,000 and 70,000,000 bbl., which, on the basis of 3½ bbl. of oil for each ton of high-grade coal, would be equal to a production of nearly 20,000,000 tons of coal. The use of petroleum by the transportation and manufacturing industries of California has practically eliminated coal as a steam-raising fuel in the State. Oil is also used in the manufacture of gas which is employed for cooking and for heating residences as well as for lighting. Oil is now also coming into use as a fuel for household purposes.

Lake Superior Mining Institute

The sixteenth annual meeting of the Lake Superior Mining Institute, which began at Crystal Falls, Michigan, resolved itself into a three days' tour of the principal producing iron mines of the Menominee range, in Iron and Dickinson counties, and an examination of improved equipment recently erected, including hydro-electric plants. The members and their guests, numbering nearly 250, occupied two trains of Pullman sleeping-cars, which, with the aid of automobiles for cross-country runs, carried them rapidly from one point of interest to another.

The first visit was to the Hollister mine of M. A. Hanna & Co., of which Frank Scadden, of Crystal Falls, is manager. Here interest centred in an ore-dryer, 6 by 35 ft., made by the Atlas Dryer Co., Cleveland, Ohio. It receives the crushed wet ore from the shaft and reduces its moisture from about 15 to 4%. The present plant, which was erected as an experiment, has a capacity of 150 tons daily. At the Bristol mine, owned by Oglebay, Norton & Co., where the next stop was made, E. W. Hopkins, of Commonwealth, Wisconsin, the manager, is sinking a new steel-lined shaft, with four compartments, to replace the old 960-ft. shaft now used, and which was started when this property was known as the Claire. The mine is now a large producer, having yielded nearly 3,000,000 tons to date. There are two grades of ore, one of which runs over 3% manganese. The company also operates the Chatham and Berkshire and owns the Quinnesec.

Crossing to the Tobin mine of Corrigan, McKinney & Co., the visitors clustered about Alvin Richards, son of W. J. Richards, the general manager for this district, while he explained the device originated by the company for arresting the descent of a cage or skip in case the cable breaks. This was recently tested when, with 17 men in the cage, it fell, but none was injured. The same company owns the Dunn, Armenia, and Tully mines, which are active, and the Great Western, Crystal Falls, Kimball, Fairbanks, and Baker, which are idle. Electric haulage is used underground and on the stockpile. Near these are the Hiawatha and Chicagoan Lake mines of the Munroe Mining Co., of which G. L. Woodworth, Iron River, is manager. The same company also owns the Munroe and Rogers mines.

A barbecue at 'Idlewild', the summer home of the president of the Institute, W. J. Richards, and a business session at Crystal Falls, closed the first day. Among the papers presented at the latter, the one on 'Safety Devices of the Oliver Iron Mining Co.' aroused the greatest interest, showing the strong trend of feeling in that direction. This was presented by Alex. M. Gow, of Duluth.

On the forenoon of the second day the Baltic and Caspian mines of the Verona Mining Co., at Palatka, Michigan, were features of interest, and considerable attention was given to the company's welfare work. The manager, Charles E. Lawrence, of Iron Mountain, Michigan, had prepared a paper on the 'Social Surroundings of the Mine Employee.' This company also operates the Fogarty, Hemlock, Vivian, and Calumet mines. Following a business session at Iron River, other properties were visited, including the new steel head-frame at the James mine of the Mineral Mining Co., E. F. Brown, Iron Mountain, manager. The same company owns the Wauseca, Osana, Nanimo, Konwinzki, and Breen mines. The day ended with a clam-bake at Sunset Lake, near Iron River, provided by the Foster Construction Co. of Milwaukee, Wisconsin.

For the third day, Dickinson county was the scene of a rapid succession of visits to mines. At the Loretto and Appleton shafts of the Loretto Iron Co., managed by J. W. Amberg, Chicago, the delegates saw where the Sturgeon river had been diverted from its course by a deep canal. The river formerly passed over the main orebody traversing the two properties, and mining by the room-and-pillar system was carried on to a depth of 800 ft. Operations now include mining out the pillars by a top-slicing and caving system, described in a paper by W. A. MacEachron, of Iron River, Michigan. The company, in diverting the river, was chiefly moved by the desire to avoid loss of life from a 'drown-out' such as that which occurred under similar conditions at Crystal Falls some years ago.

The first important event of the day was the visit to the water-power plant and the several shafts of the Penn Iron Mining Co., Vulcan, Michigan, under the guidance of William Kelly, manager, and Frank H. Armstrong, the company's engineer. For the preceding business session the latter had prepared a description of the 'Electrical Operating Plants' of the company; and inspection revealed the most complete motor-driven system in the district. The properties include the Vulcan, Norway, and Curry mines. At Vulcan about 60 delegates descended to the 1200-ft. level to see in operation two 8-stage electrically driven Worthington centrifugal pumps, working against the high head. These were in a neat concrete station. The hydro-electric plant at Loretto includes two alternating-current generators of 3500 kw. combined capacity, driven by water-turbines. The head averages only 25 ft. Automobiles then took the party to the 5000-kw. hydro-electric plant of the Peninsular Power & Development Co. under construction at Twin Falls on the Menominee river, from plans prepared by D. W. Mead, of Madison, Wisconsin. This plant will supply current to mines in the vicinity of Iron Mountain, at 66,000 volts transmission.

Returning by the Chapin mine of the Oliver Iron Mining Co., the visitors were first taken to the huge Cornish pumping-plant at the Ludington C shaft, which is unique of its kind. This was built 15 years ago by the E. P. Allis Co. for the D shaft, and recently enlarged in capacity at the shops of the Allis-Chalmers Co. prior to placing it in its present position. The pump has a capacity of 3000 gal. per minute from a depth of 1500 ft. There are 8 lifts, 6 sets being each 192 ft. apart and 2 sets 170 ft. It is driven by a compound steam-engine with cylinders 50 by 100 in. by 120 in. stroke. The 40-ft. fly-wheel weighs 160 tons. In height the engine is 54 ft. from the floor line. It was stated to the delegates that the entire product of the mine now comes to the surface through this shaft, and nearly all of the pumping is handled here. The shaft is 10 ft. 4 in. by 21 ft. 3 in., is steel lined, and is down to the seventeenth level, or 1522 ft. At present all of the machinery of the mine is operated by compressed air, with steam and electric units held in reserve. The compressor plant was originally built in 1882 at the Upper Quinnesec Falls on the Menominee river, about 3 miles from the Chapin mine. In 1903, and subsequently, the wooden flume was replaced by a steel flume 382 ft. long, 16 ft. deep, and 22 ft. wide, supported by concrete pieces 5½ ft. apart. New air-cylinders of the Corliss type have also replaced the original ones with poppet valves. These consist of 3 pairs 34 by 60 in. and 1 pair 38 by 60 in. Each pair is driven by 50-in. special twin horizontal water-turbines. A pipe-line 24 in. in diameter and 16,665 ft. long conveys the compressed air to the mine. It is built in 58-ft. lengths of ¼-in. riveted wrought plate iron.

The Oliver Iron Mining Co, representing the steel corporation, also operates the Aragon, Mansfield, Michigan, Dober, and Cundy mines in Iron and Dickinson counties, and owns the Youngstown, May, Cuff, and Forest, which are idle. O. C. Davidson is the general manager for the company on this range. In caring for the visitors on this occasion he was assisted by his son, W. F. Davidson. The tour concluded with inspection of the mines of the Pewabic company, also at Iron Mountain. This company is the third largest producer and one of the oldest companies on the range. E. F. Brown is manager.

Papers prepared for the business sessions, which are not referred to above, included the following: 'Accidents in the Transportation, Storage, and Use of Explosives,' by Charles S. Hurter, Duluth; the 'Tobin Mine Sub and

Caving System,' by Fred C. Roberts, Crystal Falls, Michigan; 'Square-Set Mining,' by Floyd L. Burr, Vulcan, Michigan; the 'Check System of Time-keeping,' by Jas. D. Vivian, Crystal Falls; 'Boiler Setting and Coal Handling,' by J. S. Jacka, Crystal Falls; 'A Diamond-Drill Core-Section of the Mesabi Rocks—No. IV,' by N. H. Winchell, Minneapolis, Minnesota; 'The Relation of Mining Interests to Forest Fires,' by Thomas B. Wyman, Munising, Mich., and 'Surveying and Sampling Diamond-Drill Holes,' by Edwin E. White, Ishpeming, Michigan. The last named paper attracted particular attention.

Mines of the district not mention in the foregoing, but whose present status was a matter of interest to members of the Institute are the Youngs property of the Huron Iron Mining Co. and the Groveland mine of the Groveland Mining Co., both managed by F. W. Youngs of Iron River; the Traders of the Antoine Ore Co., Iron Mountain, under the control of C. T. Fairbairn, Duluth; the Millie of the Dessan Iron Co., S. J. McGregor, manager, Iron Mountain; the Norway mine of the Saginaw Mining Co., which has been operated by C. W. Jones, Iron Mountain; the property at Norway of the Few Mining Co., E. C. Eastman, manager, Marinette, Wisconsin; the Zimmerman of the Spring Valley Iron Co., O. P. Doty, manager, Iron River; the mine of the Bates Iron Co., directed by Felix A. Vogel, Florence, Wis.; the Gleason of the Davidson Ore Mining Co., R. Erickson, manager, Iron River; the mine of the Florence Iron Co., E. S. Dickinson, superintendent, Florence, Wisconsin. Development is also being carried on in various parts of the district by the Wisconsin Steel Co., Rogers Brown Ore Co., Cleveland Cliffs Iron Mining Co., Republic Steel Co., Wickwire Steel Co., Iron River Ore Co., Michigan Iron Co., Blair & Gibbs Exploring Co., and others enumerated above among the active operators.

The meeting was unanimously referred to as the most successful and profitable one ever held. Everything went off exactly on schedule time—a most unusual thing for annual gatherings—and there was absolutely nothing to mar the occasion. As successor to the president, W. J. Richards, the Institute elected F. W. Denton, Houghton, Michigan, who is general manager for the Copper Range Consolidated Co. This means that the 1912 meeting will be held at Houghton. The new vice-presidents are George H. Abeel, Ironwood, Mich.; Graham Pope, Houghton, and W. H. Jobe, Palatka, Mich. Managers for the ensuing year will be M. H. Godfrey, Coleraine, Minn., and J. E. Jopling, Ishpeming, Mich. E. W. Hopkins, Commonwealth, Wis., and A. J. Yungbluth, Ishpeming, Mich., were re-elected, respectively, as treasurer and secretary.

Western Australian mining companies have been investigating fire risk, and the following recommendations are contained in an interim report of the committee appointed by the Council of the Chamber of Mines:

1. That the mines be requested to provide suction tanks at suitable points as suggested by the district officer of the Fire Brigades Board. The sizes of pipes to be ascertained and the mine engineers to consult the district officer as to the best methods to be followed.

2. That each mine be furnished with the particulars of annual charge for connection with the Boulder fire station by electric fire-alarm.

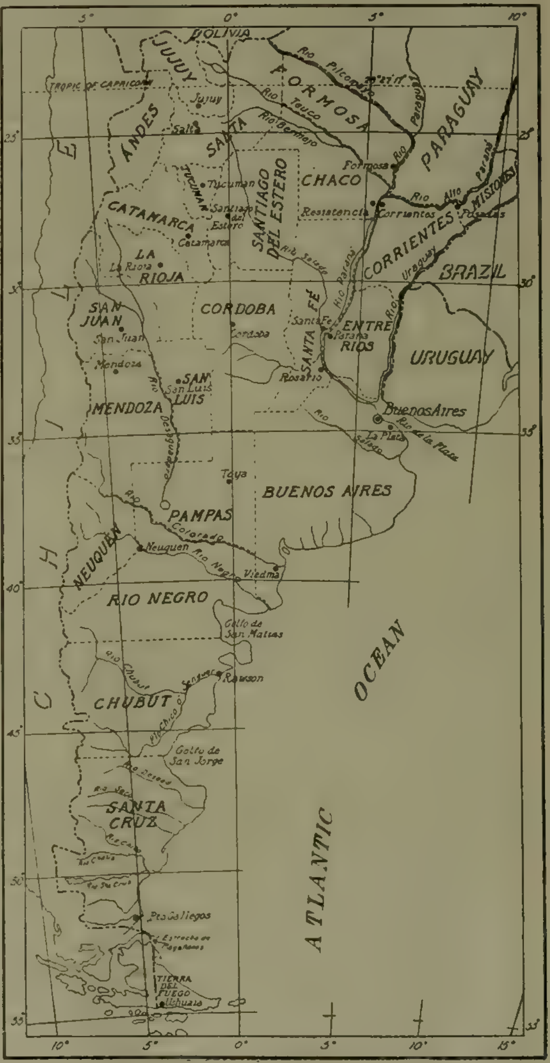
3. That in case of fire in a mine, instead of one long continuous whistle, the alarm be given by a series of short whistles.

4. That all high-voltage electric currents be cut off on the outbreak of fire.

Tin cans are in demand at the lead smelters of the Joplin district. One man makes more than a comfortable income by gathering them, frequently selling $5 to $10 worth of cans a day to the Galena lead smelter. His record day was $42. The demand for cans at this and the lead smelters in Webb City and Granby, Mo., is always excellent, the cans being used for fluxing purposes. Old scrap iron of any description also is employed.

Oil in the Argentine Republic

Little has been known of petroleum in the Argentine Republic, as practically all of the product has been imported in a refined state, and, until quite recently, no interest taken in the industry. In the States of Mendoza, Salta, and Jujuy, and the Territories of Neuquen and Chubut, oil has been discovered in paying quantities, and these districts are now under extensive and systematic development. Surface indications were most encouraging at Comodoro Rivadavia, Chubut, and, after three years of persistent exploration, several producing wells have at last been brought in, at depths ranging from 770 to 1835 ft., and a spring of petroleum at 1738 ft. The product is an excellent grade of petroleum, comparing favorably with that from the famous fields in Pennsylvania and Ohio. The Argentine Government and one private company are now operating in this district. A high-grade petroleum has also been struck by an English company at San Rafael, Mendoza, at a depth of 705 ft., and it is reported by experts that the well is flowing consistently at the rate of 80 barrels daily, and that other wells can be sunk within 125 to 150 ft. of this location and yield similar results.



STATES OF THE ARGENTINE REPUBLIC.

One per cent of the water of the ocean would cover all the land areas of the globe to a depth of 290 feet.

Mining in Papua

By Hugh Mahon

*British New Guinea and its adjacent islands contain some 850 white settlers and 300,000 aboriginal natives. The latter contribute nearly 70% of the £50,000 annually raised by taxation, the customs tariff being wisely adjusted to that end. The exports last year totaled £101,100, of which gold (16,151 oz.) accounted for £60,000, and copra £24,500. But for a fortunate discovery of alluvial gold on the main island, at a place called Lake Kamu, the gold yield would have been the lowest for the last 14 years. Even this place would not pay if worked under Australian conditions, but the bulk of the labor is performed by the natives at from 10s. to 20s. per month and their food. Operations at Milne Bay and Kiveri have been abandoned, and little is now heard of the Yodda, Gira, and Aikora fields. Now that the placers have been almost exhausted, more systematic prospecting for veins must be undertaken. In the Astrolabe ranges, behind Port Moresby, copper lodes are still being worked, but the output has fallen from 137 tons in 1909 to 72 tons last year. No fresh details are available respecting the discovery of coal in the Gulf country, but it may prove of first importance, owing to its proximity to the Torres Straits passage, where a coaling station would be invaluable.

The only goldfield visited by the Federal party was that at Woodlark Islands, a group to the northeast of Papua, about 450 miles south of the equator. The native name of the island is Marua, and the aborigines are of a good type, working freely for the miners for £6 per year and under, one year being the term of engagement. The island is mostly of coral formation, the southern end being very mountainous. The port of entry to the Woodlarks is called Bonagai. Only small craft can approach Bonagai, deep-sea ships being obliged to anchor some few miles out. As this necessitates the transhipment of all cargo into lighters, the cost of handling is considerably increased. The chief mining centre of the Woodlarks is at Kulumadau, about two miles from the coast. The mine is reached by a good, if somewhat narrow, pathway, coated with coral, which winds through a gorge, choked on either side with tropical vegetation. After emerging from the steamy atmosphere of the ravine, visitors are refreshed by the cool, bracing breezes which play around the hilltop. Mining is not retarded at Woodlarks by the absence of water, for the average rainfall there is 15 ft. per annum.

The Kulumadau mine is held by a Charters Towers syndicate, and employs 40 white men and some 240 natives, 60 of whom are engaged in mining operations. The remainder are employed in cutting and hauling wood and stores to the mine. White miners receive £5 per week, or £1 per day in shaft-sinking, and 16s. 8d. in the stopes and levels. The mine has been worked for about 11 years. An old shaft, down 420 ft., was abandoned owing to defects, and a new one started, which is now 309 ft. deep. The property is well equipped with machinery, which includes a Huntington mill, two hoisting engines, boiler, air-compressor, and cyanide appliances. There is also a tramway from the bay to the mine, worked by mules, which is shortly to be discarded for a locomotive. The company is duplicating the battery and adding to its other plant.

In the early stages the Kulumadau hill was worked for surface gold, and material from an open-cut is still being put through the mill. It carries a fair amount of gold—up to 20 dwt. to the ton. The company is working a huge lode on which coral is superimposed, and when calcite is found gold is met in heavy patches. The output averages 250 tons per week, but this should shortly be increased. Everything that comes up is put through the mill, and the yields vary from 18 to 25 dwt. The concentrate is worth £50 per ton.

Much richer, if less developed, properties than Kulumadau are being operated in the immediate vicinity. In every case the prospectors are working alluvial formations as well as the reefs. Some of the returns so far obtained would be regarded as phenomenal in Australia, and cannot be expected to continue. For instance, at Karavakeen, seven miles distant, McLeish and party have crushed with a small Huntington mill 20 tons with a yield of 600 oz. Slater and party, in the same locality, won 728 oz. from 80 tons. McLeish holds 21 acres; he put one shaft down 110 ft., but was driven out by the water, having no appliances to cope with it. From this shaft 150 tons, estimated to be worth 3 oz. to the ton, have been taken. The vein in this shaft is from four to five feet wide. The high grade ore crushed by Slater came almost wholly from the surface. He has driven 270 ft. into the hill, where the vein is said to be 20 ft. wide, and worth an ounce per ton. Slater's property was discovered eight months ago, but he has a good deal of ore already waiting the advent of a 25-head mill now on its way to the mine. Three or four others are at work in the same locality, but developments are not sufficiently advanced to express any opinion as to their prospects.

At Busai, some five miles from the port, Wickley and party are working both veins and placers, for Busai is rich in the latter. They have a 5-head mill. Several veins have been worked down to water-level, where the ore was worth 13 dwt. per load, but a hoisting plant is essential to any additional exploration. In the same locality George Jones has a promising property, which has already given 33 dwt. per ton from 300 tons of ore. The shoot of gold is 200 ft. long and 4 ft. wide.

At another place, named Wonai, ten miles southeast from Kulumadau, alluvial gold is still the mainstay of the prospectors. The veins so far opened show profitable prospects. Here, as at Busai, and Tinkarai, the country rock is mostly metamorphic and igneous, showing occasionally large fissure-veins.

During our stay at Woodlark, I had an opportunity of meeting E. R. Stanley, a graduate of the School of Mines and University of Adelaide, who was recently appointed Government geologist. As Mr. Stanley had been only a month on the island, he avoided offering any pronounced views of its auriferous potentialities. But, speaking generally, he had seen sufficient to make him sanguine as to the future. Most of the alluvial miners, he said, were doing excellently. The general trend of the lodes was northwest, but the subsidiary lodes were rather irregular. The country rock appeared to have undergone primary fracturing, thus forming a certain amount of breccia with subsequent impregnation of quartz containing the gold. The sulphides partly replaced the quartz and vein stuff by a process of metasomatism. The rocks are of metamorphic and igneous origin; and on these (which contain the metalliferous lodes) is superimposed the coral limestone. Several of the hills are survivals of what were formerly islands in the coral sea. Others again, older rocks from which the coral capping has been denuded, are now being worked for gold, while alluvial deposits are found both above and beneath the coral. "These ridges," said an intelligent prospector of ten years experience in the island, "must at one time have been islands. Between them you find the coral country. Wherever the country rock outcrops there—with few exceptions—you find gold. Sufficient work has not yet been done in tracing the veins under the coral to speak definitely as to their ultimate value. The creeks in the coral country where gold has been found have invariably 'headed' from gold-bearing country rock."

The importance of the Woodlarks to Papua may be inferred from the fact that 43% of the total gold won in the territory has come from these islands. The gold is unfortunately not up to standard, the highest price being £3 9s. per ounce. If mining in Papua advances, the Government will need to appoint an inspector of mines and machinery. At present there is no officer specifically charged with the duty of seeing that shafts, stopes, and drifts are safe, or that the safety appliances are in good

---

*Abstract from the *Australian Mining Standard*.

order. Such supervision is apparently left to the mining wardens, already overladen with administrative functions, few of whom have any practical knowledge of mines or machinery. Doubtless this appointment will be made as soon as practicable, for the resources of the Government are slender, and are being drained by the many imperious calls made by the pioneer settlers, as well as by the needs of the native population.

Time did not permit of an inspection of the extensive Gira and Yodda goldfields, where hundreds of prospectors at one time found profitable occupation. Speaking to an experienced Government official who had just left that locality, I was assured that fortunes await those who introduce modern methods. He states that claims have been worked over and over again, and yet remain profitable. The miners are unable to work the creek beds when the water is low, a freshet suspending operations indefinitely; and when claims are located away from river or creek, time is lost at every spell of dry weather. An expert who recently tested the district was equipped with only a hand-pump, which was quite inadequate, owing to the volume of water to be contended with. It is understood that he will shortly return with a dredge, results having satisfied him of the prospects of dredging and hydraulic sluicing. My informant adds: "A little trouble was lately experienced on the Yodda field, owing to miners' boys being attacked by men from one of the adjacent villages; but, on account of the measures taken by the Government, it may now be considered perfectly safe to allow 'boys' to go almost anywhere alone. Any miner working with, say, ten 'boys' will consider that times are extremely bad if he cannot make an ounce of gold per working day, despite the fact that his total working expenses do not come to a third of that sum."

Under the existing conditions, only the banks and shallow portions of the rivers can be worked, and it is only natural to suppose that a large amount of gold must remain in the deeper water, which has never been touched. As soon as definite news of the result of the trial dredge is obtainable, it may be confidently stated that a great impetus will be given to the industry. Hydraulic sluicing would also appear possible at profit. The country is eminently suited for it. In many places—notably in the Upper Aikora district—sufficient power can be obtained to raise water to any required height. In other places steam pumps would be required. There is no doubt that profitable gold exists over a large area. Hundreds of men in the past have made good livings there. The reason for the exodus of miners is the report of extremely rich returns from the Lakekamu field. The few men remaining are all well satisfied with their returns. The only drawback to the country is the fever. This is rather bad. As it is mostly only ordinary malaria, there is not much to worry about. Blackwater fever is rare. On the whole, capitalists desiring to help forward a good paying industry might do worse than make inquiries from the Government of Papua concerning the Gira and Yodda goldfields.

ELECTRIC ARCS and high-tension discharges through gases are capable of producing some chemical compositions and decompositions which are very useful, and profitable to operate. This is a branch of electrochemistry which has not been as thoroughly studied as some others, its phenomena are not as thoroughly under control as electrolysis and electro-thermal reactions, and its possibilities are not as thoroughly understood or utilized.

TUNGSTEN was found in 1898 at Trumbull, Connecticut, and it was worked at a profit for five years. The ore is along the planes of contact between crystalline limestone and two bodies of hornblende and schist. The tungsten occurs as wolframite and scheelite. A modern mill was built containing Blake crushers with a capacity of ten tons per hour, Cornish rolls, revolving screens, Wolf gyrating screens, and dry-concentration by the Hooper pneumatic concentrator.

Segregation of Solids in Liquids

By M. P. Boss

Drop a pebble in a pool of water and with it will follow a limited zone of liquid impelled by pressure in front, skin friction, and suction from vacuum behind. Two pebbles dropped in contact tend to keep together because in the wake of one is the line of least resistance and because of the difference in resistance the hindmost will press upon the one forward. If they have unequal and flat faces it is possible for them to be deflected into separate paths. A cluster of pebbles dropped together will tend to hover to the same path and are individually less exposed to deflecting influences and thus a zone of pebbles and liquid moves downward. If light material is enveloped within that zone every tendency is for it to remain there in the downward course, unless some exterior interruption occurs. If, instead of into a pool, a mixture of heavy and light grains is dropped into a body of water having an easy flow at near horizontal, the agglomeration will sag as it drifts, giving a lengthened path of travel and an exposure to disturbance of the zone aggregation by the flow of water across the gravitation path and a segregation of the light material from the heavier is affected. Because of these principles, settling and segregation are better accomplished with an easy lateral flow than when the flow is vertical, as with a cone where the inflow is central, either upward or downward. An easy rotary movement imparted to the content will facilitate segregation and better accomplish settling. Further than this, a cone centrally fed with an overflow of the lighter material, without lateral movement, must needs overflow evenly throughout its circumference, or efficiency will be curtailed in ratio to that part of the circumference which does not overflow, as that represents a segment of the cone not in action.

A liquid body at absolute rest holding in suspension very fine and light solids deposits those solids more slowly than if there is a mild movement, or changing of relative positions. It has not been rare to observe in a tank of exceedingly light slime, after it has stood for days, a top stratum of clear water overlying a slime still in suspension. It is probable that such a condition is due to confined air cells, the aeration having been effected in the crushing, though it is not possible with all methods of crushing.

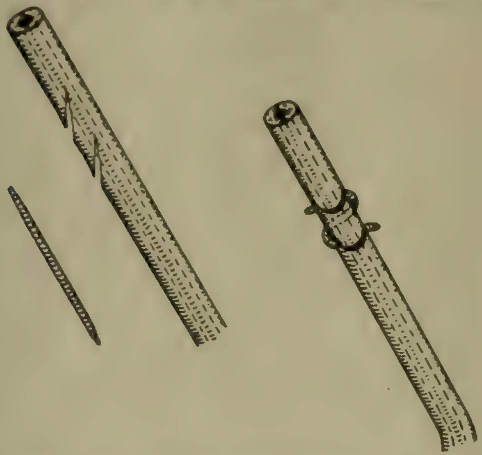
The flow of liquid through a tank or within confines develops a current of unequal activity, it naturally moving faster away from the walls and being the most quiet at the corners.

Interposed baffle plates, when there is a movement not too violent, have a marked effect favorable to precipitation. This is well exemplified in dust-laden gases seen in smelter or roaster settling-chambers. It would be futile to attempt to depict all the complex reactionary currents in a body of liquid through which a current passes, but it is well understood that a current passing a quiet pocket will create a 'whirlpool eddy.' If a high-pressure nozzle of water be submerged in a quiet pond, it will set into movement a large mass, increasing in width and decreasing in force with increasing distance from the nozzle. This propelling of water from its place of rest would create a vacuum only that there is an inflow from behind which is compensated by the circular return of the outgoing flow, thus creating a whirlpool eddy on either side of the outflow from the nozzle. This principle of current compensation enters into all conditions of flow of slime or pulp laden liquid, from a Wilfley table top to a large settling vat, and what has here been called a 'whirlpool eddy' may have a vertical axis or its axis may be inclined or horizontal. If baffle plates are of the type called 'over and under,' that is, where the current passes over one baffle and under the next, the axes of the whirlpool eddies generated would be horizontal. On the other hand, if the baffles are staggered right and left with vertical openings between a plate and the opposite side, the eddy axis would be vertical. In one case the precipitating material would pass diametrically through or from a rotating zone, while in the other case precipitation would parallel the axes. It is easy to believe that the latter would be the most highly efficient for settling purposes or for classification.

New Method of Lighting Fuse

By E. M. Weston

*I cut two nicks in the fuse about ¼ in. apart. I then open a stick of gelatine and cut from it very thin strips about the size of whip cord and from 1½ to 1 in. long. I then insert one end of this small strip into one cut, and twist it round the fuse so that it cannot be accidentally detached, and insert the other end into the other cut. Then I close both cuts. It will be seen that I am using a minimum quantity of gelatine, about a fifteenth of a gram. One gram will be sufficient to fire a whole round of holes. There is practically no vitiation by fumes, and I have this advantage also, that I have two chances to light the core if the gelatine in the first nick should fail to light. To light these fuses which are primed with this small amount of gelatine, I do not employ a 'cheesa stick.' The miner who carries a 'cheesa stick' inhales the maximum amount of the most poisonous fumes possible to generate in a mine. If a miner burns even the half of one small stick of gelatine he vitiates the air to an alarming extent. Nearly every miner is supplied with tobacco bags (that goes without saying), and if he will only take the trouble to take a tobacco bag and wrap it round a candle, tying it with numerous separate pieces of string, he will have a torch which is very hard to put out and which gives a more convenient light. It will last half a dozen or more times, and if required it can be bound by wire to the end of a stick. With the fuse made up in the manner indicated, it may be taken that he can absolutely depend, even more than with a 'cheesa stick' on getting the holes efficiently lighted.



Hydrocarbons in Brazil

Although an abundant supply of bituminous shale, containing about 40% of carbon, has been gathered in various places in the vicinity of Bahia and employed for many years in the manufacture of candles, paraffine, and commercial oils, it was generally believed that petroleum would never be found in paying quantities in Brazil except, perhaps, in the valley of the Amazon. An official report from Santos states, however, that petroleum has just been discovered at Ibitinga, São Paulo, and that a company is now being organized to develop the industry in that district. A low-grade asphalt is found in Bofete, São Paulo, bituminous shale at Taubate, and vast clay deposits of a sedimentary character along the Parahyba river, which consist of interstratified shales, containing about 21.11% of carbon, and have been used to a limited extent in the manufacture of gas and oils. At Camamu, on the Marahu river, rich and extensive deposits of lignite are found, from each ton of which it is estimated three barrels of oil can be manufactured. Lignite is also found in great abundance at Gandarella and Fonseca, Minas Geraes. An expert examination of the lignite from Gandarella shows that it contains 40% volatile matter and 48 of fixed carbon, and that 200 lb. of the product will produce 850 cu. ft. of gas.

Chilean Nitrate in 1910

According to a report by A. A. Winslow appearing in the *Daily Consular and Trade Reports*, the production of nitrate during 1910 broke the highest record, reaching the high-water mark of 50,781,331 quintals (a quintal weighs 101.61 lb.), against 46,579,656 for 1909. The consumption for the year ended June 30, 1910, was 51,981,561 quintals, against 40,263,282 for the previous year. The increased consumption was largely due to the work of the Nitrate Propaganda backed by a working fund of $601,070, of which the Chilean Government paid $194,640. The United States consumed 12,672,262 quintals during 1910, against 7,988,121 for 1909. Shipments of nitrate to other countries in 1910 were as follows, in quintals: United Kingdom, 19,010,443; Germany, 10,653,573; Belgium, 2,126,128; Netherlands, 1,220,576; France, 1,810,993; Italy, 1,154,569; Sandwich Islands, 425,412; Japan, 369,600, and British Columbia, 97,822. The exports of nitrate for the first 45 days of 1911 exceeded those for the same period in 1910 by 2,507,648 quintals. During the year more American capital was invested in the nitrate fields of northern Chile, and negotiations are under way for several additional properties.

Copper in Urals

The quantity of metallic copper smelted in the Urals in the first four months of this year amounted to 6,440,335 lb., or about 1,083,300 lb. more than in the corresponding period of last year. The leading copper producer was the well known Bogosloff concern, which contributed 2,420,000 lb., followed by the Kyshtim company with 2,020,000 lb., the Visk company with 725,000 lb., the Pyshmin-Klyutchievsky company with 620,000, and the Polievsky company with the same. The Paschkoff smelter in the Verchotur district was closed.

Appraisal of Copper Mines

By J. R. Finlay

[*]This report is a calculation of the value of mines to the permanent owner for the production of minerals. It is based on three factors: (1) average cost; (2) average prices; (3) an estimate of future life. The first two factors are determined by experience. The third factor, the life of the mine, is based partly on undeveloped ore and partly upon an assumption of continuance of known orebodies beyond the present bottom levels of the mines. The assumption of continuance is based mainly upon the extent to which the continuity of the deposits has been proved for the district and for the type to which the mine belongs. It will be seen that these factors are quite as definite as those upon which calculations in the world of business are generally founded.

The future value of a series of dividends is reduced to a present value by the annuity method: that is, a sum is calculated upon which the series of dividends will pay 5% interest and also provide each year a sinking fund instalment which, invested each year at 4% interest, and added to prior instalments similarly invested and reinvested, will equal the sum taken. This sum is the amount which an investor can afford to pay for the property.

Table of Present Values for a Series of Dividends.—The following is a simplified table showing the present value on the above basis of a series of dividends for different periods.

A single dividend of $1 payable at the end of a year is worth	$ 0.95
A dividend of $1 continuing—	
Two years	1.85
Three years	2.70
Four years	3.50
Five years	4.26
Ten years	7.50
Fifteen years	10.00
Twenty years	11.96
Twenty-five years	13.51
Thirty years	14.74
Thirty-five years	15.73

Unprofitable Mines Have No Value.—The reasoning from these factors is pursued to its consequences. No definite value can be placed on any property for which any of the factors cannot be determined. Whenever the working of a mine proves that expenditures will equal or exceed receipts from products at average prices, the property has no value at all, and it is appraised at zero.

Stock Market Valuations Not Considered.—It will be observed that this method makes no mention of quoted values. It may be asked, and is asked, why it is that if the products of mines are valued by the process of purchase and sale, the mines themselves should not be so valued? If the price of wheat, copper, and iron is fixed by the sales on an exchange, why not mining stocks? My answer is that wheat is good to eat. Like copper and iron, it is a staple and necessary article, tangible and definite. The value of these commodities is universally recognized, whether they are quoted on exchange or not, and prices fluctuate only with the varying pressure of demand. Mining stocks do not represent anything definite. Some pay dividends, in which case their quotations are comparable with those of other securities, but in the majority of cases mining stocks represent nothing more tangible than hopes. They fluctuate wildly as these hopes rise and subside. The very fluctuations make these stocks useful for gambling. People buy them not as serious investments, but as temporary speculations; often knowingly paying far more than they are worth, on the chance of selling them to somebody else for still more. In many cases this sort of thing has been organized into a business which depends not on any intrinsic value in the properties, but wholly upon gambling. For this purpose the stocks are prized not because they are stable, but because they are unstable. A notable instance of this is that of the famous Comstock mines of Nevada, which have scarcely paid a dividend in thirty years. On the contrary, the assessments have reached astounding figures, probably over a score of millions. The assessments paid by stockholders merely take the place of prizes paid by lotteries, serving no purpose except to perpetuate the gamble. The public, of course, is fed with tales of the marvelous possibilities of these great mines and their past record is pointed to often enough. Still it is doubtful if many of these shares are sold to a gullible public. They are mainly bought and sold by seasoned gamblers, with whom it is a case of 'dog eat dog.' While this is an extreme case, it is wholly true that gambling forms an element to be reckoned with in every district where trading in mining stocks has become established. The copper district of Michigan is no exception. There are in it cases of terrific fluctuations in stock values. The Arcadian mine was valued at one time at $12,000,000; a few years later at $60,000, by stock quotations.

These reasons make it evident that the use of stock quotations in a serious appraisal of mining properties is illogical and beneath the dignity of a sovereign State. But, if the method is illogical, it is certainly impracticable, because in Michigan the ownership of mines by stock companies, whose shares are traded in, is confined to a single district—the copper mines. The much more important iron mines are owned mainly by outside corporations or partnerships simply as so much private property. No available quotations apply to them even remotely. It is obviously necessary to use a method that will apply fairly to all properties throughout the State.

Valuation of Mineral Lands on Which Workable Deposits Are Not Developed.—It is plain that where no deposits have been worked and none have even been proved to exist, the definite factors which can be applied to the valuation of an active mine are lacking. In this case no definite appraisal can be made. A figure only represents a guess. I can see no way to come to any conclusion about such lands, other than to attempt such an analysis of the facts as may limit the range between which guesses will be reasonable. In this connection it seems desirable to discuss one or two points of difference between mining and other forms of business.

The mining business may properly be distinguished on the ground that an essential preliminary is the discovery of a deposit in the crust of the earth that is inherently valuable. A sufficient quantity of rich gold ore in the remotest desert is valuable as soon as it is discovered. The *discovery* is valuable. The commercial problem of utilizing the ore can so certainly be solved that no one is much concerned about it. Such a deposit can only be valuable because it is limited in extent, consequently its size and the time it will last are points of great concern and a most essential factor in the value that can be put upon it. With minerals less valuable and more common—less valuable *because* they are more common—the commercial circumstances of a discovery play relatively a more important part. A copper mine in the interior of Alaska is not valuable unless it is large enough and rich enough to pay for a railroad to reach it. An iron mine in the middle of the Sahara would have no value at all, even if a railroad ran across it. In other words, an iron discovery, to be valuable, must be within the range of certain commercial conditions. The value of coal is still more a question of mere environment. It is so abundant and can be mined at so many places that the question of an assured market is far more vital to commercial success than the discovery of a seam of coal. When we come to still more common minerals, such as limestone, salt, gypsum, and brick-clay, we find that they are so enormously abundant that the discovery of them excites no comment whatever. It is doubtful whether the discovery of salt, for instance, is of any value. The ocean is full of salt. Deposits are known in Michigan which would apparently supply the whole world for thousands of years. The utilization of such minerals, therefore, is wholly a commercial question, and I am disposed to draw a line between mines and other industries on the simple ground of whether the mineral rights on which they are based have value or not.

---

[*] Abstract from a report to the Board of State Tax Commissioners of Michigan.

Many industries, which no one thinks of calling mines, use minerals and even mining processes. The Pennsylvania railroad has for years been conducting the mining operations of shaft sinking and tunneling for the purpose of developing its terminals in New York City, but nobody calls the railroad a mine or New York a mining camp. Similarly, we do not find a sufficient reason for calling the brick-maker and the cement manufacturer miners because the first digs clay and the second dredges marl. If, however, brick clay were a limited product valuable enough to make the mere hope of its discovery on a tract of land a sufficient reason for placing a higher value on that land than it would otherwise have, then we might properly call brick-making, mining. Some distinction of this sort appears absolutely necessary in order to differentiate intelligently between mining and a vast group of manufacturing industries that use minerals.

There are in Michigan large tracts of land highly prized for their possibilities of containing valuable mineral deposits. These lands are mostly in the iron and copper regions of the Upper Peninsula. It has been a large feature of the work connected with this appraisal to tabulate the ownership and distribution of such lands, and attention has been given to the problem of working out a scheme of valuing them on a rational basis. The results will be taken up later in connection with the specific reports on the iron and copper fields. It is only worth while to point out here that the iron and copper ores of the Upper Peninsula have proved so valuable that their mere discovery carries a high commercial value. The mere chance of making such a discovery on a given tract of land is distinctly an asset. This is particularly true in the iron regions where the ores occur in masses of rock which are so unique that they can be instantly recognized, and in which the probability of discovery of merchantable ore is considerable. The finding of the 'iron formation', therefore, can be considered a part discovery of ore, and it is undeniable that lands containing it have in the aggregate a large commercial value; a value that is not speculative but actual. But since I am now speaking of lands on which no merchantable discoveries have been made, it must be admitted that a valuation which may be reasonable for the aggregate of such lands may be wholly mistaken when applied to any particular tract.

Mining Plants Not Appraised.—The value of a mine depends wholly upon the ore; that is, the equipment of a mine has no value except as applied to the ore. It is, therefore, useless to appraise mining plants as if they were in themselves an asset. It is true that a mine cannot be worked without equipment. A mine fully equipped is more valuable than a mere orebody without equipment, but this fact is fully taken into consideration in all appraisals. The point to be especially borne in mind is that mining equipment in itself is of no value; when the ore plays out the equipment is mere junk, no matter how costly it may have been in the first place; and this junk is so likely to be unsaleable that it is fully as likely to entail expense for watchmen and insurance as it is to yield any salvage. This fact may be surprising to many people, but a little consideration will show that it is true. The equipment of a mine consists largely of structures that cannot by any possibility be moved. The shafts and all other excavations are a part of the equipment. The buildings and machinery may occasionally yield some salvage, but necessarily a small amount. It must be borne in mind that a large part of the expense of any installation of machinery consists of labor and materials for foundations, housing, and erection. This is wholly lost when it is proposed to move the machine. Furthermore, the value of a machine depreciates rapidly on account of mere age.

Meaning of Appraised Values.—The valuations in this report are intended to cover the value of the mining business of a company in each case. It includes all value that can be put on mineral lands and mining, milling, and smelting equipment and mining supplies. It does not include property that can be valued for purposes other than mining, such as surface rights of any kind, agricultural or timbered lands, houses, stores, merchandise, or cash.

Price of Copper. For the purpose of appraising the copper mines, I have decided to apply to the future a price of 14c. per pound. This is considerably above the price ruling during the summer of 1911. The Calumet & Hecla Mining Co. states that the actual sum received for all copper produced by that concern, from 1878 to 1910, inclusive, has approximately been 13½c. per pound. For the 20-year period from 1890 to 1909, inclusive, the average price of a given amount of copper sold each year by the Quincy Mining Co. was approximately 13.7c. per pound. As there seems to be some evidence that the Quincy secures a slightly higher price than the other Lake companies, this would give ground for taking 13½c. as a fair figure.

My own belief is that the average price of copper is tending to rise. It appears that for the last fifty years the price has fluctuated widely. Periods of high prices have occurred at an average interval of about eight years, separated by intervening periods of lower prices. Following the high price of 1899 the average fell in 1902 to 12.16c., but in 1910, following the much more severe panic and depression of 1907, the average price has gotten down only to 11c. It remains to be seen what the average of 1911 will be. One might assume from these figures that the price has risen at least 3c. per pound since 1904 because, following the panic of 1907, the price has not fallen to within 3c. per pound as low as it fell in the depression following the panic of 1893. It is also probable that another wave of high prices will culminate about 1915. The trend of these figures is such that the stockholder in a long-lived copper mine has reason to hope that the average price for the future, taking a period of ten to twenty years, will be, perhaps, 15c. per pound. My conclusion in 1909, after making a rather exhaustive study of the copper mining business, was that the average price for the ten years following would be 15½c. per pound.

Much stress has been laid on the overproduction of copper due to the bringing in of numerous mines during the past few years. The situation, however, is far from terrifying, as consumption is increasing at the rate of one hundred million pounds per year. It appears that at the beginning of 1911, the expected increase of production from new mines would amount to some three hundred million pounds per year. This is only sufficient to meet the increase of demand for three years. After that period is passed the prospects for a scarcity of copper are fully as good as that new sources of supply will be added. The discovery of new deposits has practically ceased on the North American continent. Even the so-called porphyry deposits which have been opened in the States of Utah, Nevada, Arizona, and New Mexico within the past ten years, are not strictly new. Their rapid exploitation has been rather the result of finding how to treat them successfully. Since that was accomplished an urgent search has been made for further deposits of this type (which is not essentially different from that of the Lake Superior copper mines), but with no success. Claims have been widely published by the promoters of these porphyry mines that they could produce copper cheaper than older mines in other districts. This claim will not stand analysis. So far as costs are concerned, the porphyry mines are in essentially the same situation as other mines. Some can produce copper cheaply and others cannot. It is highly doubtful if their average cost will be even as low as that in the Lake Superior district.

I recite these facts, not to cast any doubt on the value of the new mines in the West, for they undoubtedly contain the greatest reserves of available copper known in the world today. But it is easy to overestimate their effect. They are not likely to disturb the copper industry as did the discovery of the Mesabi range, the iron.

Concentrates

Most of these are in reply to questions received by mail. Our readers are invited to ask questions and give information dealing with the practice of mining, milling, and smelting.

THE first railroad steam-shovel in the United States was built in 1882 by the Bucyrus company and was still in use a few months ago.

CAPACITY of grinding pans varies greatly but at Kalgoorlie a 5-ft. pan working on 30-mesh feed will crush 12 tons per day so that 90% will pass 150 mesh.

FIRE CLAYS may be analyzed by any chemist, but for final determination of their value a burning test is desirable. A number of works are equipped for making these tests.

ANTIMONY is not now smelted in the United States and only small lots of ore are produced. Sample lots may be marketed through the smelting and metal-buying companies.

FULMINATE of mercury is never used commercially as a blasting agent on account of its prohibitive price and the extreme danger in handling it. It is only handled in homeopathic doses and with the greatest care.

PHOSPHATE rock can be tested by any reputable chemist, as the principal point to be determined is the amount of phosphorus present. Sale of a phosphate property, like any other, is a matter of individual bargaining.

NEWFOUNDLAND, in the vicinity of Port au Port Bay, has large and promising asbestos deposits, but is prevented by its inaccessible location from participating in the rapid development now in progress in the Canadian field.

SODIUM BICARBONATE statistics are not available except as to imports. These in 1910 amounted to 73.2 tons valued at $4472. Figures of domestic production are veiled in general statistics of the industry. The imported salt is worth about $80 per ton of 2000 lb. at the wharf.

CALIFORNIA has a mining law which took effect July 1, 1909. It supplements the Federal mining law as to delinquency of a co-owner and the making of a record thereof and in other particulars, but it does not affect nor abolish any mining district nor the rules and regulations thereof.

FULLERS EARTH is used mostly by refiners for decolorizing oil. Small amounts are employed for various other purposes, but as is true of a number of the earthy minerals, control of a market is more important than control of a deposit. Consumers buy direct from producers or own their own deposits.

THE ROOF STRATUM over most coal seams is shale, which when hard, is called slate by the miners. Shale generally weathers badly and in a majority of coal mines, the entries must be timbered more or less continuously. If the shale were protected from the action of the ventilating currents it would require little support.

VALDEZ is situated at the head of Valdez bay, an extreme northerly indentation of Prince William Sound, on the southern coast of Alaska. The bay is the farthest north port in the world, free of ice the year round. It is a deep-water harbor, twelve miles long and three miles wide, entirely landlocked except the entrance.

SHAFT LANDINGS or bottoms in European collieries are usually built with masonry side walls and arched roofs, both for fire protection and for permanence. Such arched passages or drifts contain from two to four tracks, and where double-decked cages are employed, are sometimes arranged with corresponding upper and lower stages requiring considerable height.

NITRATE OF SODA is derived from caliche deposits in Chile which, as worked, contain 18 to 50% nitrate. These are concentrated by methods described in detail by S. H. Loram (*Mining and Scientic Press*, January 15, January 29, 1910). The material is refined to a strength of 95% or over $NaNO_3$ before exporting. The material is sold through brokers, and prices vary as in other commodities. At present, in San Francisco, nitrate is quoted at $2.07 per hundred, future delivery in the harbor.

ASBESTOS occurs in two varieties, the serpentine (chrysotile) and the amphibole. The former is the more valuable. Georgia and Vermont are the chief asbestos producers among the United States; the former ships amphibole and the latter chrysotile which is reported by manufacturers to compare favorably with that imported from Canada. The production in Wyoming and Idaho has advanced, but in those States the industry is still in the development stage and has not become permanently established.

DOUGLAS FIR, a common Western species, yields lumber that has many defects. These may be classified as pitch seams and shakes, cross-grain, and knots. Practically, these are the basis of all grading rules, and their number and character largely determine the use to which the product of the sawmill is put. Material which is free from them is usually manufactured into finish, flooring, and other high-grade products, in which the appearance of the wood is of prime importance. Also, it is generally believed that, aside from their effect on the appearance of the wood, these defects influence greatly the strength and other mechanical properties of the timber in which they occur.

WHEN a vein is discovered that seems worth development, the locator will do well to locate claims on either side of the original location, if mineral in place can be found on which to base a discovery. These side claims will 'protect' the original location from encroachment by others. Particularly is this desirable in the case of unusually wide lodes. Occasionally a mineral vein or zone is wider than the limits of the claim, and this fact has been the occasion of several law suits. In one of these a Territorial court decided that the prior locator having the apex, took the whole lode, even though it extended beyond the side line. In the Coeur d'Alene were several such cases, and others in Utah.

SALT in air-pipes was suggested recently for the purpose of taking up the water. Responding to a request for criticism, E. A. Rix says: "There is such a large amount of water condensed under ordinary conditions that it would require a large amount of salt, which cannot be well introduced into the pipe itself, and if it was introduced in a separate drum there are other materials which are better than salt, such as chloride of calcium. It would be certain that some of the air would finally reach the rock-drill impregnated with salt, which would ruin the machine, so I would not consider this a desirable method. My experience with compressed air has been limited to mild climates where there is little trouble with freezing of pipes and therefore I do not feel competent to discuss the subject. If I were, however, to undertake to solve the problem I think I would pass the air after leaving the compressor through a bath of cold water, the colder the better, for the cooler the air the less moisture it contains. I feel sure if the air after leaving the bath was the same temperature as the water there would be no tendency for the air to further deposit moisture in the pipes. In fact the pipes would probably be warmer than the water which cooled the air, and thus the tendency would be to take up the moisture in the pipes rather than to deposit it."

Special Correspondence

LONDON

Alluvial Tin at Goss Moor. Lead Mining in the North of England.

A year ago I mentioned in this column that a new venture had been started for the purpose of working the alluvial tin deposits at Goss Moor in mid Cornwall. As we are in the midst of the vacation season, it is appropriate to say that this district is midway between Newquay on the north coast and Fowey on the south, the former noted for golf and the latter for yachting. It is reached by the railway that passes through the beautiful Luxulyan valley. It is on the northern side of the granite outcrop associated with the china-clay industry. Here are great tracts of swampy land that contain stanniferous clayey gravel. From time immemorial they have been worked in a desultory way, and records show that quite 50,000 tons of cassiterite has been recovered at one time and another. The nature of the gravel, however, was against permanent success on any large scale. J. H. Collins, the Cornish veteran, has always been in favor of the application of modern dredging methods, and he is now a director of the company that has been formed to work the property under the technical management of C. G. and F. M. Lush. The method adopted is to dig a pit and build a barge containing sluice-boxes, then break down the gravel by means of monitors, and elevate the débris from a sump by means of a suction pump to the sluice-boxes. When the bank of gravel has been removed for a certain distance and the barge is too far away from the face, the pit is flooded and the barge floated to another position. This method is the ordinary Australian practice. When the plant was first erected at Goss Moor, gas-engines were employed for the generation of power. For some unexplained reason these have been reported to be unsuitable to the work, and have been replaced by steam-engines which went into commission last month. The area belonging to the company covers 800 acres, and much of it has been sampled by boring. From the results obtained, it appears that the recovery is $1\frac{1}{2}$ lb. of cassiterite per cubic yard. The total cost, including royalty, is estimated at 6d. per cubic yard, so that a profit will be made whenever metallic tin is over £60 per ton. At the present price, two-thirds of the proceeds of sales would be profit. The plant can treat 40 cu. yd. per hour, or 220,000 cu. yd. per annum. If estimates are borne out by results, other barges are to be built.

The district where the counties of Cumberland, Durham, and Northumberland meet has long been a producer of lead and zinc ores. It is in the high ground at the northern end of the Pennine chain which runs from the Cheviot hills on the Scottish border southward through Lancashire, Yorkshire, and Derbyshire. At the northern part, the rock is chiefly Carboniferous limestone, and the valleys of Tynedale, Allendale, Teesdale, Weardale, etc., have in days gone by been populous with miners and smeltermen. At the very highest point is Alston and Nenthead, well known names in mining records. In Weardale, on the Durham side, are many lead mines that are still being worked by the Weardale Lead Co., which, though its office is in London, is controlled by Newcastle people. The Boltsburn mine is the chief producer of galena, and others are the Stanhopeburn, the Sedling, and the Wolfscleugh. At the Boltsburn, production is temporarily reduced because of the extra development that is being done, so that the results for the twelve months ended June 30 are not so favorable as for the previous year. The actual amount of ore and concentrate from all the mines that was sent to the smelter during the twelve months was 3129 tons, yielding 2664 tons of pig lead selling for £12 15s. 6d. per ton, as compared with 4199 tons yielding 3402 tons of lead during the previous year. An interesting point in connection with this group of mines is that fluorspar has been extensively worked of recent years since the demand from steel manufacturers increased. During the past year over 16,000 tons was sold, bringing an income of £7,500. The larger part of it came from the Stanhopeburn mine. The company distributed £1800 as dividend for the year, being at the rate of 5%, as compared with 10% the year before. The extra work and expense of development at the Boltsburn has been well worth the while, and in succeeding years the output should substantially increase. The manager, Errington Thompson, to whom is due the present excellent position, resigned recently and was succeeded by H. S. Willis. It is of interest to note the announcement made by the board that Herr Professor Doctor Henry Louis of Newcastle-on-Tyne has been appointed technical adviser.

SALT LAKE CITY, UTAH.

Equipment of Ohio Copper.—Park City.—Tintic.

While the financing of the Ohio Copper Co. has been progressing slowly, and not altogether satisfactorily, the operating end has been making strides. The latest step has been the signing of a contract with E. A. Wall, whereby the latter will complete the erection of crushing machinery giving the concentrator a capacity of 3000 tons daily. A further increase to 6000 tons will be possible without increasing the roof space of the mill. The company has been using Gates rolls, each taking the product from Blake crushers and handling 400 tons per day. For about three months a set of Wall corrugated rolls has been taking the product from the Blake crushers and treating an average of 1000 tons daily. It is stated that the applied horsepower was 18, as against 38 for the other type of machinery. Another set of the corrugated rolls has been doing the work of a small Blake crusher and the Gates rolls combined. The contract calls for the erection of 10 corrugated and 10 vertical, fine-crushing rolls, which should be completed in three months. The mill has been treating a total of 1500 to 1700 tons of ore per day, and the improvements will practically double the capacity. According to men connected with the ownership of the property, the mine now has 12,000,000 to 14,000,000 tons of ore developed, with probable additional tonnage, partly developed, of 5,000,000 to 6,000,000 more, averaging 1.5% copper. In addition, there is a large amount of virgin ground. The mill recovery is said to be better than 70%. Following recent meetings here between large interests in the Ohio Copper, the statement is made by local shareholders that F. A. Heinze will retire from all connection with the company, and that the bond issue will be subscribed. With the reorganization completed and the mill in operation at 3000 tons per day, the Ohio should be turning out 20,000,000 lb. of copper annually.

OHIO COPPER CO. MILL.

Action will be taken by stockholders of the Daly company, September 20, and the Ontario company, October 10, on the proposed consolidation. These two companies have been controlled by allied interests ever since the Daly was organized, and they have many holdings in common. It is proposed to form a new corporation with 300,000 shares, par \$5. Of this stock, 150,000 shares are to be exchanged for Ontario stock, share for share, and 75,000 shares for

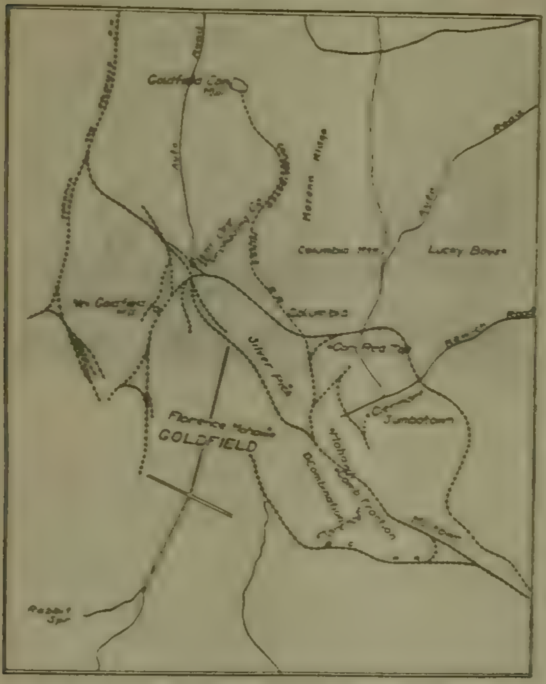
Daly stock, on the basis of one share in the new company for two of Daly. This will leave 75,000 shares, and about $136,000 cash in the treasury.

In the Tintic district the May Day mine, as a result of the new smelter charges, is shipping slime from its mill dump as well as ore which has been left in the mine for years because it would not pay to ship. The Yankee Con. also has closed a contract which has resulted in the company beginning shipments of about 15,000 tons of ore from its mine dump, running as low as $9 per ton in silver, lead, and gold. The Scranton mine, at North Tintic, has run into a big body of lead carbonate, in addition to other favorable developments. It shipped 950 tons in August. Most of the ore runs high in zinc, but the new ore shows a higher percentage of lead.

GOLDFIELD, NEVADA

CONSOLIDATED DISBURSEMENTS. — AUGUST PRODUCTION. — IMPROVEMENTS AT FLORENCE GOLDFIELD. — GOLDFIELD BELMONT.

Total dividend disbursements of the Goldfield Con. Mines Co. will have reached the sum of $18,146,183 upon the payment of dividend No. 13, at the rate of 50c. per share quarterly and amounting to $1,779,574, declared last week at the meeting of directors in San Francisco. This dividend is the regular quarterly payment of 30c. per share with an extra 20c., and is the eighth consecutive quarterly payment of like amount. It is payable October 31 to stockholders of record September 30. According to preliminary estimates, the production in August was 30,580 tons, or nearly 1000 tons daily, with a gross recovery of approximately $800,000 and net profits of $500,000. This is the largest tonnage produced in any month of the company's history. The average of the ore was $20.60 net, as against $18.80 for July. Some of the richest specimens of high-grade produced by these mines have been taken from the 1000-ft. level of the Clermont and from the intermediate level, 100 ft. below on the incline of the vein, and some exceedingly rich ore is said to have been exposed on the 1200-ft. level of the Grizzly Bear. Milling ore is being taken from the old Jumbo workings, which have been repaired and equipped with a 50-hp. electric hoist and compressor. This affords the Consolidated seven producing shafts, all well equipped.



The Florence Goldfield mill is treating 170 tons daily and has shown a notable improvement in point of recovery since the elimination of concentrators and vanners and the introduction of Akins classifiers and a Dorr thickener. Reduction is now effected almost entirely by amalgamation and cyanidation, much of the elevating has been done away with, the process of feeding is performed automatically to a large degree, and many important economies have been effected, the saving in the item of labor alone being placed at $25 daily. On the 500 and 650-ft. levels new cross-cuts are nearing points where the downward extension of highly productive orebodies should be found. Sinking has been temporarily suspended a short distance above the 900-ft. level in order to straighten timbering that has been slightly displaced by swelling ground and to prepare the station on the 800-ft. level and start lateral work on this level. The shaft will be continued with but little delay to the 1000-ft. level, and from the 900-ft. or tenth level a main drift will be driven to the north to open the bonanza Reilly ore-shoot some 1200 ft. from the shaft.

Engineers of the Goldfield Belmont company state that on the 300-ft. level they have exposed 3 ft. of $200 ore, containing seams of high-grade that carry in some places $10 per pound and an undetermined quantity of good milling ore. This is said to be the downward extension of the ore-shoot from which lessees shipped a good tonnage of $75 to $100 ore from the 50 and 150-ft. levels. Assays of $1400 per ton gold were obtained in the winze sunk from the 150-ft. level. The company has started to sink at a point over 1500 ft. southeast of the old shaft.

JOHANNESBURG, TRANSVAAL

STATISTICS FOR FIRST HALF OF YEAR.—PRODUCTION SATISFACTORY.—DIAMOND INDUSTRY.

According to the returns issued by the Mines Department the value of the mineral output of the Transvaal during the month of June was £3,064,526, this not including diamonds, the details of which are only issued half yearly. Of this total, gold constituted £2,912,484, coal £87,745, and other metals and minerals, consisting of principally tin, silver, and copper, £65,197. To obtain this output of gold 2,061,525 tons was milled. The Rand alone yielded 658,121 oz., valued at £2,795,550 from a crushing of 1,995,525 tons. Coal has now become so cheap in the Transvaal that in the principle centres where it is now being produced it only realizes 4s. 5d. per ton at the collieries. Despite these low prices, however, the output of coal is steadily increasing. Among base metals and minerals tin continues to occupy the leading and most promising position, the amount produced in June being £34,971, while copper showed a record monthly output valued at £8718.

The issue of the June mine records by the Transvaal Mining Department enables a comparative statement to be compiled, showing what progress has been made during the last twelve months in the Transvaal. The following figures are interesting because they show the progressive nature of the gold industry since the war:

Year ended June 30.	Oz.	Value.
1903	2,372,075	£10,075,926
1904	3,475,311	14,762,184
1905	4,322,577	18,361,144
1906	5,199,935	22,087,937
1907	6,271,697	26,640,590
1908	6,711,436	28,508,368
1909	7,294,711	30,985,966
1910	7,308,551	31,044,753
1911	7,848,872	33,339,891

With regard to the growing use of machine-drills on the Rand, it may be pointed out that during the last 12 months the average total number in use has increased from 3577 to 4286. The output of silver as a by-product from the gold mines reached, during the year ended June 30, a total value of £94,533, being, like gold, a record output. Although the diamond-mining industry during the last six months has shown a marked improvement, it has not yet reached the standard attained during the previous five years, the total number of carats produced in the Transvaal being for the year ended June 30, 1,795,007, valued at £1,266,992, as compared with 2,098,527 carats, valued at £1,317,479 during the previous year. The highest output obtained was in the year ended June 30, 1908, when 2,184,490 carats were produced, valued at £1,879,551. The previous year, however, had the record value of £2,203,511, with an output of only 1,545,335 carats.

ALPINE, TEXAS

K. C. M. & O. Extensions.—Van Horn Silver Mines.—Discovery of Cave Springs Mine.—Iron Mining Beginning.

The authoritative announcement that the Kansas City, Mexico & Orient railroad has made financial arrangements for the immediate construction of the division of its line between Alpine and the Rio Grande, a distance of about 80 miles, is stimulating mining, prospecting, and development in the mountainous territory adjacent to the route. While it has long been known that the Chisos mountains contain copper and silver, the remoteness of the region from railroad transportation has retarded the exploration of these minerals. The Llano Gold & Rare Metal M. Co., which recently erected a 50-ton mill at its Heath mine near Llano, shut down the plant after a brief run. The trouble is said to have been due to the water that was being used. In order to provide a better supply a pipeline is being laid from the mill to the Llano river, two and one-half miles, and the company expects to soon have the plant in regular operation again. It claims to have large quantities of gold ore blocked in the mine, and development operations are being steadily conducted. The holdings of the company embrace about 200 acres of mineral land. J. C. Hoy is preparing to reopen the San Panzo mine in the Van Horn district. The Black Shaft mine, also in this district, and which was formerly well known as a producer of rich copper and silver ore, has been taken over by a syndicate of Minnesota men, and it will soon be again producing. The workings extend to a depth of 300 ft. T. H. Lewis, who recently acquired a silver claim in the Davis mountains, is preparing to start development. Two mining prospectors recently discovered what is said to be the lost Cave Springs gold mine, situated 12 miles from Alpine. Rich specimens of ore were taken from the ancient shaft. The exploration that was made of the workings indicates that the property was at one time worked on a large scale. This mine was a producer in the early days when hostile Indians roamed this part of the State. It was an attack by Indians and the massacre of all employed and connected with the mine that caused it to become 'lost.' L. F. Serdell and associates, who recently acquired several cinnabar prospects in the Terlingua district, will soon begin development. They plan to build a furnace when the mines have been brought into the proper producing state. The Texas Brown Ore Mining & Development Co. is erecting an iron-ore crushing and washing plant of 1000 tons daily capacity at its mines near Ore City, Cass county. The plant will be finished about October 1, by which time the Port Bolivar Iron Ore railroad, now being constructed from Longview to the mines, will be finished. The company is doing extensive development work at the mine.

MOTOR WAGON USED FOR TRANSPORTING ORE IN TEXAS.

TORONTO, CANADA

New Townsite. Dome Find. Rea. Cobalt News.

The Porcupine branch of the Temiskaming & Northern Ontario railway will immediately be extended across the Pearl Lake district, following the contour of the lake through the Hollinger property to the Campbell Veteran claim, where a new townsite has been laid out. The town will bear the name of Timmins and will begin with a considerable population. A sale of lots by auction is announced for September 4. Building in South Porcupine is active; fully 150 buildings are in the course of erection and more are being planned. A sensational discovery has been made on the Dome property. Trenching operations carried on about 600 ft. east of the present workings disclosed a quartz vein 18 to 20 ft. in width with showings of free gold said to greatly exceed in richness anything hitherto found in the district. The patches of gold interspersed in the quartz are described as varying in size from a pinhead to a dime. The speculative character of the find has created much excitement, though it has singularly failed to infuse any activity into a very dull stock market. The vein has been followed for 72 ft. and is believed to run into the Dome Extension. At the Hollinger two new veins have been uncovered on the north lot. One of them varies from 2 to 9 ft. in width and has been traced for 350 ft.; the other, 15 ft. wide where struck, is being followed. Both show free gold. The Imperial has opened up a good vein 5 ft. wide on the northwest corner of the property, and a 7-ft. vein has been found in driving at the 100-ft. level. No. 3 shaft of the Dobie is down 50 ft., and it is expected that the vein will shortly be reached, as several stringers carrying gold have been found. The Plenarium is sinking two shafts, one on the north and the other on the south side of Pearl Lake. A plant comprising an 11-drill compressor, a 200-hp. motor, and an auxiliary steam-plant has been ordered. The Porcupine Reserve has uncovered a new vein 35 ft. wide on the Birke location for 500 ft. and satisfactory assays have been made. The West Dome has purchased the half interest owned by Elijah Woodward and associates in the two Kertz claims immedately adjoining. The Bewick-Moreing company has been requested to resign the management of the Rea mines on the ground that the company has the services of a high salaried engineer, rendering the Bewick-Moreing management a needless expense. C. Plumer Hill, president of the Rea, has issued an interim report stating that the underground situation has improved somewhat. At the 200-ft. level the ore-shoot is 50 ft. longer than at the outcrop. The 200-ft. level has been driven for a distance of 310 ft., and it is intended to sink to 325 ft., and to continue the west shaft, which is now down 137 ft. At the Pearl Lake the diamond-drill has struck mineralized schist at the 400-ft. level, assaying $19 per ton. The new goldfield of West Shining Tree, 40 miles north of Gowganda Junction, is attracting large numbers of prospectors. Many claims have been taken up and free gold is said to be plentifully in evidence. The most notable property is the location staked by Alfred Gosselin, the pioneer of the camp, who has a 10-ft. vein of quartz showing free gold throughout.

The difference in the policies of the two leading Cobalt companies, the Nipissing and the La Rose, in the matter of dividend payments, has been a frequent subject of comment. While the former has been distributing its liquid assets freely and depending on its ore reserves as a means of keeping up the rate, the La Rose has been conservative in the extreme in the accumulation of a large cash surplus, now approximately amounting to $1,400,000. There is no reason to suppose that this policy will be changed. Differences of opinion on this question are assigned as the cause for the resignation of D. Lorne McGibbon, of Montreal, president of the La Rose, from the Nipissing directorate. The amalgamation of these companies was at one time regarded as assured, but recently the boards represent a diversity of interests which shows them to be farther apart than ever. The refining plant of the Nipissing is now in successful operation, treating most of their first-class ore, and when existing contracts have run out will refine all of it, at an estimated saving of $30,000 per year. Experiments are being conducted to find out whether the second-class ore can be profitably treated at this plant. The new 20-stamp concentrator of the Cobalt Lake will be in operation in a few days. At first it will treat some 75 tons per day, the full capacity being 100 tons. The McKinley-Darragh has declared the regular quarterly dividend of 3% with a 7% bonus, and the Weltlaufer has declared a quarterly dividend of 2½%, with an extra dividend of 2½ per cent.

NEW YORK

Estimates of Copper Production.—Market Situation.—Nevada Hills.—Pioche.—Greenwater.

Discussion of the copper situation seems futile at present, in view of the market developments. July figures showed a reduction of some twenty million pounds in stocks on hand. In the face of this apparent movement, the metal market weakened and copper shares have shrunk until the quotations show a staggering total loss. The figures for August do not promise to make any material change in the situation. Exports are estimated to total about 62,000,000 lb. for the month and domestic deliveries about 60,000,000 lb. The refinery output is more uncertain. July output was light, owing to intense heat, which curtailed operations. August will undoubtedly show higher figures, though the present copper situation will hardly be affected one way or the other. One of the factors militating against any advance in the mining-share market is the plight in which the Lake coppers find themselves. The original appraisals made by the Calumet & Hecla committee and also by J. Parke Channing were unsatisfactory to many holders in the smaller companies. The pending litigation and the ensuing deadlock have brought trading in the Boston copper share market to a standstill. The general impression now seems to be that if the Calumet & Hecla directors can find an excuse that will allow them to declare the whole merger plan off and at the same time save their dignity, they will be very glad to drop the whole project. J. R. Finlay predicts much higher prices for copper within the next few years. If, as he seems to think, the next decade is to see a rapidly declining production of Lake copper, then the overtopping strength of the developing porphyries seems not to be so much of a menace to higher prices for the metal. In the meantime Ray Con. and Chino are making progress daily. The former is just putting into commission the fourth unit of the mill and a tonnage of 3200 per day is being handled. The mill is making an extraction of 70%, and the four units are expected to turn out concentrate containing 100,000 lb. of copper each day, or 36,000,000 lb. annually. This production, little more than one-third of what is expected from the property eventually, has already placed Ray on a comfortable profit-earning basis. One of the queer market phases is that, now when real results are being obtained daily, the shares have no followers in the market and sell for less than one-half the price quoted a year and a half ago. Chino is sending ore to the bins in readiness for the starting up of the first unit of the concentrator some time during the first of the current month. Three sections of the mill are to be running before January 1 next.

The patience with which the followers of Nevada Hills have held on is apparently soon to be rewarded. The 120-ton mill which the company is erecting is to go into commission within a few days. When Goldfield Consolidated 'went inside,' which is the street phrase for admission to the New York Stock Exchange, it was hoped that the Goldfield interests would make of Nevada Hills another market leader for the Nevada issues. The trading has, however, been quiet, and while earnings of $600,000 annually are now reasonably assured, there has been no sign of improved mine conditions reflected in the market.

The Nevada-Utah situation has not cleared as yet. It seems almost impossible for anything to go through with Nevada-Utah without becoming involved in endless complications. E. R. Woolley, who was made president last year, has resigned, and Robert G. Mead has been elected to fill his place, while representatives of L. Vogelstein & Co. have been placed upon the boards. Mr. Mead was recently chosen as head of the Amalgamated Pioche M. & S. Cor., and it is said that litigation is expected because of a refusal on the part of the officials to recognize any obligation on account of certain Amalgamated Pioche bonds. The Nevada-Utah organization long ago became too complicated for analysis by any except skilled accountants, and the present snarl will only add a further touch to the general scheme.

PRINCE CON. SHAFT, PIOCHE, NEVADA.

The Greenwater Copper M. & S. Co., a concern into which were merged nearly all the companies organized on the strength of the copper showings at Greenwater, has utilized a small cash balance remaining in the treasury in securing a long-time working lease and option on a group of 27 claims at Dale, Colorado. The Greenwater boom enlisted a multitude of followers in the East, and for each penny now invested in Colorado there were dollars put in.

BUTTE, MONTANA

August Copper Output.—Production Stationary.

The copper production of the Butte mines for August is estimated at 23,030,000 lb., as against 23,132,045 lb. for July and 22,691,200 for June. The daily record for August, showing tons of ore mined daily, pounds of copper per ton of ore, and total pounds of copper produced for the month, is shown in the following table:

	Tons ore mined daily.	Lb. per ton of ore.	Lb. copper.
Boston & Montana.....	3300	63	6,444,900
Anaconda	3800	60	7,068,000
Butte & Boston.......	400	61	756,400
Washoe	310	60	576,600
Trenton	400	60	744,100
North Butte	900	62	1,729,800
Butte Coalition	850	68	1,791,800
Tuolumne	150	140	651,000
East Butte	310	120	1,153,200
Original	1100	62	2,114,200
Total			23,030,000

General Mining News

ALASKA

FAIRBANKS

An interesting occurrence of platinum-bearing rock has been found on Rose creek, a tributary of Gilmore. The platinum is found in a green basic rock, probably diabase, which carries 0.1 oz. of the metal per ton. The find was made by Brown & Flynn. A shaft is now being sunk on the Ryan Lode, by the owners of the property. Dave Thomas is in charge of the work. If the showing warrants the expenditure, a mill will be ordered later. This property is between Eva and St. Patrick creeks. A new vein has been found near the head of Ester creek by Tyndall & Finn, after considerable hard work at tracing. The overburden is deep at this point, making prospecting slow.

SEWARD

The U. S. S. R. & M. Co., in opposition to the Guggenheim interests, has sent experts to the Seward district to investigate properties. D. D. Muir, in the employ of the company, has visited quartz properties along Willow creek.

PRINCE WILLIAM SOUND

James Galen, reported to be a representative of the Guggenheim interests, has bonded the Big Climb, Big Climb No. 1 and 2, and Pioneer No. 1 and 2 claims. The price is said to be $30,000. The present owners are William Mattson, H. B. Cooper, and E. Evans. Of the price, $600 is to be paid before November 1, and the final payment is to be made before January 1, 1914.

The Ibex Extension M. Co., capitalized at $1,000,000, has been incorporated to develop claims on the glacier adjoining the Ibex M. Co.'s property. John Beckman, formerly of Nevada but now of Valdez, Ben Silverman, and G. M. Fay are the incorporators.

The rich vein discovered on the glacier, on the Valdez M. Co.'s property, is persistent in depth, according to latest reports. William and Joseph Crary found the vein 120 ft. from the surface and 50 ft. from the upper adit.

ARKANSAS

BOONE COUNTY

In the Arkansas district, great activity is noted in the zinc mines, and reports of good shipments are heard. A new mill just put into commission in that region is operated by Shortz & Sons. It is in Boone county near the Missouri & North Arkansas railroad. Several other mills are under course of erection. One in particular, that of the Morning Star Co. at Yellville, is deserving of note. It is to have a capacity of 250 tons and will be the largest zinc plant in the North Arkansas field.

ARIZONA

GILA COUNTY

W. F. Goodsell and Thomas Leonard, leasing the U. & G. Copper Co.'s Geneva group, shipped their first carload of ore to the smelter. The ore assays from 10 to 12% copper, according to report.

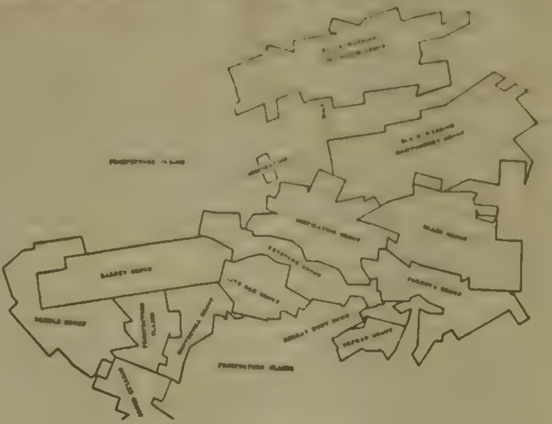
Operating three and a half sections of its mill, the Miami Copper Co. is now producing about 1,800,000 lb. per month, states the *Boston News Bureau*, at a cost of about 9c. per lb. f. o. b. New York. It is the expectation of the management to be able to have the remaining half of the No. 4 section in commission by October 1, and by the end of the year, or early next year, to have the entire six sections in commission, when the Miami should be able to produce about 40,000,000 lb. per annum, at a cost of about 8c. per pound.

(Special Correspondence.)—It is rumored here that the consolidation of the Live Oaks. Dev. Co. and the Inspiration company is contemplated. Five drills are in operation at the former property, and two more are being taken there from the Inspiration.

Miami, September 5.

MOHAVE COUNTY

The Tennessee mine, operated by the Needles M. & S. Co., has penetrated the orebody on the 700-ft. level. The new Oro Plata mill is under construction, and will have a complete equipment. From the 180-ft. level to the bottom level of the Oro Plata property, in Tood basin, large bodies of high-grade ore are in the stopes, according to newspaper reports.



PORTION OF GLOBE DISTRICT.

PINAL COUNTY

The Douglas Copper Co. has been formed to develop 14 claims adjoining the Ray Con. The incorporators are T. C. Fredericks, W. Isher, and Fred L. Mason.

CALIFORNIA

ELDORADO COUNTY

(Special Correspondence.)—The Stanton Mining & Roasting Co., capitalized at $200,000, has been formed here to manufacture apparatus invented by George A. Stanton for a process designed to prevent the discharge of destructive fumes by smelters. The company will use the apparatus first in connection with its mines near Placerville before attempting manufacture on a commercial scale. The incorporators are C. G. Sebring, S. H. Maginess, E. L. Anderson, George A. Stanton, O. E. Bailey, R. E. Marshall, A. T. Johnston, and I. E. Stacy. Principal place of business is Placerville.

Placerville, September 4.

KERN COUNTY

The Honolulu Con. Oil Co. has developed a 20,000-bbl. gusher on section 10, East Midway field, state newspaper reports. The new well is said to be deeper than the gas well near which it is drilled. The oil is under control and is being pumped into steel tanks. It is of high grade and is near the apparatus for extracting gasoline from natural gas which recently was placed on the property.

MARIPOSA COUNTY

(Special Correspondence.)—The Mountain King mine is blocking ore for its stamp-mill. Ten stamps are dropping at present. William S. Thomas is superintendent for the company.

Mt. King, September 2.

(Special Correspondence.)—The 5-stamp mill of the Mariposa Mining & Commercial Co. is milling high-grade ore from the leases on the Mariposa Grant. F. T. McGuire is planning to sell the Grant mine.

Bagley, September 3.

NEVADA COUNTY

(Special Correspondence.)—The Pennsylvania Mining Co. is arranging for the heaviest production in the history of the property. The 10-stamp mill formerly at the Morning Star mine has been purchased, and will be immediately placed in position. This will give the mill a total capacity of 30 stamps. The adit at the Le Duc has been advanced 1000 ft. and is expected to soon intersect the main orebody. Cross-cuts are being extended to prospect cross-veins. A 14-hp. gasoline engine and compressor have been installed. The 10-stamp mill at the Union Hill is nearly finished. It is planned to send the shaft deeper and open new levels. Good ore is blocked out at several points. It is rumored that J. M. O'Brien and associates of San Francisco are negotiating for the You Bet gravel property, owned by Goodwin & Nichols, of Dutch Flat. The property is situated near the old hydraulic mining town of You Bet, and was formerly a noted hydraulic producer. Several years ago Chinese worked the property by drift methods, and extracted large amounts of gold. The Pacific Gas & Electric Co. will construct an immense storage reservoir in the upper portion of the county and will build a hydro-electric plant which will furnish power to mines above Nevada City.

Grass Valley, September 4.

SIERRA COUNTY

(Special Correspondence.)—In the North Fork mine, near Forest (George F. Stone, manager), the bottom of the old Uncle Sam incline has been reached, and one of the old North Fork drifts is being followed. The operators expect to penetrate quartz in a short time which is probably a continuation of the Tightner vein at Alleghany. This mine is being watched with considerable interest, as the old North Fork company, in early days, when little was known of quartz mining, took out $100,000 in specimen rock passing through this lead.

Considerable excitement has been caused lately, in Alleghany, by rich discoveries made in the Red Star mine, now controlled by San Francisco mining men; $25,000 has been taken out during the past week in specimen ore and rich arsenical sulphides. One piece of rock was shown weighing 26½ lb. and valued at $2500. This ore is being taken out at the 'grass roots.' A long adit, to tap the vein several hundred feet deep, is being run by machine-drills along the Tightner vein, of which the former is known to be a continuation. The Tightner is controlled by the same interests.

A compressor and drills are now being put in at the Kate Hardy mine below Forest City, and systematic development is being started. This vein is about 20 ft. wide and reputed to run $4 per ton average outside of the rich shoots.

Nevada City, September 4.

TUOLUMNE COUNTY

(Special Correspondence.)—The machinery for the additional 20 stamps to be placed in the Dutch mill is on the ground, and grading will be completed in a month. Concrete motar blocks on the old 20 stamps now in place will be one of the improvements. Charles Segerstrom, of Sonora, is manager of the mine.

Stent, September 2.

(Special Correspondence.)—As the result of extensive tests at the 40-stamp mill at Black Oak Flat, the flow-sheet of the Black Oak M. Co. is to be changed from amalgamation and concentration to fine grinding and final treatment by agitation in an improved Pachuca (Brown) tank. Two central lift-tubes with auxiliary air-jets will be used. R. S. Knox is superintendent of the mill.

Soulsbyville, September 4.

(Special Correspondence.)—Several members of the company which is to operate the Wards Ferry gravel claims, on the Tuolumne river, inspected the property recently. It is said to have been decided to procure a dredge and begin active work as soon as possible. It is reported a company is being organized to operate the Crystalline mine, which for some time has been in the hands of C. E. Shafer.

The Bonita G. M. Co. has sold the Bonita mine and mill-site to Charles S. Neal and William Angus. The Contention mine, in the Knights Creek district, has been assigned to the Rio Tagus M. Co. by Albert B. Dodd and J. S. Silva, who receive as consideration 399,750 shares of the capital stock of the company. An option on claims two miles northeast of Sugar Pine has been given by W. N. Sledge to Perry Tyer, who will conduct prospecting operations on the property. The price is $10,000, payable within two years.

Tuolumne, September 2.

YUBA COUNTY

Sensational showings of gold are reported on the Last Chance vein at Dobbins, 30 miles from Marysville, the nearest railroad point. The Last Chance shaft is down about 25 ft. The vein of high-grade ore has been followed for 20 feet.

COLORADO

CLEAR CREEK COUNTY

(Special Correspondence.)—The West Bellman mine on Bellevue mountain is yielding about one carload of smelting ore daily. Returns on the last shipment were 2.68 oz. in gold per ton. Owen & Lowell are operating under lease. The Kate S. property at Alice has been leased by Peter Sweeney to Fred Bigelow. Stoping is in progress on a 12-in. streak of ore that mills 5.70 oz. gold per ton. The Waltham mill that was recently remodeled started up last week upon custom ore. W. S. Leebrick is owner. David Jones, leasing on the Gem Extension property, has opened a 20-in. streak of ore that mills $28 per ton in gold and silver. Bunny & Co., leasing on the Beaver mine on Chicago mountain, are sending out shipments of ore that mills $62 per ton in gold and silver.

Idaho Springs, September 2.

GILPIN COUNTY

The Sun Tunnel Mining & Transportation Co. has been formed with a capitalization of $1,000,000, to develop about 50 properties, all in one group, on South Boulder creek between Rollinsville and Tolland, near railroad points. E. T. Butler is manager. William A. Jordan, Galesburg, Ill., and D. T. Davis, Findlay, Ohio, are officers of the company.

OURAY COUNTY

The Revenue Tunnel M. Co. has granted a lease to the Cimarron, Bradley, Memphis, and Ophir claims, lying on the Cimarron and Memphis properties, to the Cimarron M. Co., which has just been organized with W. H. Gay as superintendent. The lease originally was granted to H. M. Adkinson, who interested New York and Chicago capitalists. The 40-stamp Cimarron mill and compressor are included in the lease. An aerial tram from the Crane washer to the mill will be built.

(Special Correspondence.)—A. A. Kelsey, secretary of the Camp Bird, Ltd., of London, in a report to the stockholders at a meeting in London, states that the "extracted profits" of the Camp Bird mine in the Mt. Sneffles district for the year ended April 30 were £227,000 and that the ore reserve at that date was estimated at £85,000. He also stated that negotiations are under way to secure nearby property available for the mill. The company also is interested in the Santa Gertrudis company of Mexico.

Ouray, September 4.

SAN MIGUEL COUNTY

Mining for radium, in connection with vanadium and uranium, has brought the United States Steel Co. and other powerful interests into keen rivalry in western Colorado. Options have passed on practically every group of promising claims, so great is the demand for the ground; and although the development up to the present time has not been extensive, 20 four-horse teams are kept busy hauling ore from the Paradox valley, fifty miles, to Placerville, the nearest railway point. From Placerville it is taken 200 miles over a narrow-gauge line, transferred to broad-gauge cars, shipped to Galveston, and thence by water to Liverpool.

TELLER COUNTY

Members of both companies deny a report circulated last week that the Portland G. M. Co. and the United States R. & R Co. were to consolidate. The Portland company is changing its mill from the chlorination to the cyanidation process, but this action, which has been under way for five months, is merely in accordance with old plans.

IDAHO

Idaho County

(Special Correspondence.)—At the Moscow mine, in the Big Creek district, owned by M. E. Moore, there has been opened on three sides a vein of free milling gold ore 200 ft. wide and 3000 ft. long, to the depth of 70 ft. The ore assays from $5 to $12 per ton. A 5-stamp mill which yields by amalgamation $40 per stamp has been built. The owner has bought a 10-stamp mill, and intends to use the cyanide process.

Charles Ellison, owner of the Red Metal mine, has discovered a vein of gold-silver ore, not free milling, assaying on the average $1000 per ton. The property is in the Big Basin district. The Iavada M. Co. has opened a vein assaying over $200.

The Eagle M. Co., near Edwardsburg, will start its new 10-stamp mill in a short time. The company has about 5000 tons of $30 ore opened, and is driving a 500-ft. adit to cut the vein at 350 ft. The company has expended about $125,000.

Warren, September 2.

Shoshone County

The Espirito M. Co., capitalized at $1,000,000, has been formed at Wallace. The property consists of six claims on the north side of Bear gulch, about six miles east of Murray. It is claimed the ore shows wire-silver. Officers are H. H. Wilmot, president and manager; W. M. Myers, vice-president; and H. H. Reeves, secretary-treasurer. All live in Murray.

GENERAL VIEW OF WALLACE, IDAHO.

Articles of incorporation for the Edna-May M. Co. have been filed at Wallace. The company is capitalized at $500,000. Directors are D. W. Peeples and J. M. Scott of Wardner, and R. P. Scott, of Newport, Washington.

The semi-annual report of the Stewart M. Co. shows concentrate returns for the six months ended June 30 to be $299,435; ore returns were $21,373; miscellaneous revenue, $57; interest and exchange, $242; patents, $200; total, $321,109. The total operating expenses were $170,608, and the total sundry expenses were $9904. The net profit for the period was $140,796, or an average of nearly $25,000 per month. Preparations are being made to drive a long adit which will give greater depth on the orebody and lessen the cost of production. It is said that the indebtedness has been wiped out and that the proposed adit will assure dividends, if, indeed, they are not declared before its completion.

MAINE

Cumberland County

Oil has been found near Portland. Drilling is being done with the expectation of finding a basin of petroleum with coal deposits overlying it.

MICHIGAN

Houghton County

While only once before last March did the monthly output of the Mohawk M. Co. exceed 1,000,000 lb. of refined copper, present indications are that in the future the production seldom will fall below this figure, according to recent reports. For several months the recovery has been 16 lb. refined copper per ton. Improvement is general throughout the mine, but the greater importance is attached to the young shallow southerly shafts, as the northerly shafts are down 2000 ft. No. 6 of the former group commands about 150 acres. The extraction through No. 2 and 4 shafts permits dismantling No. 3 shaft.

The August output of the Franklin M. Co. exceeded the monthly record of the past two years by about 100 tons, according to preliminary estimates. The lower levels show more heavy copper than the upper levels, it is affirmed. With the new hoist and 32 new tables, it is stated, the company can treble operations and show a profit on a 12½c. market. It is believed that in a few months the mill will be stamping 1200 tons of ore per day, instead of 400 tons as at present. The new equipment has a capacity of 2500 tons per day.

A director of the Quincy M. Co. is quoted anonymously at Boston as stating that the company will continue its present dividend rate of $4 per annum if the price of copper does not drop below 12c. The present cost of production is 10¼c. per pound, and it requires $440,000 to pay dividends on the stock at the present rate.

The Calumet & Hecla company has declared a quarterly dividend of $6 per share, making a total of $116,050,000 paid in dividends by the company since its formation.

The Wolverine Copper Co.'s July output was the smallest for several months, 790,399 lb. The average recovery was 24.21 lb. per ton. The ore stamped was 32,645 tons, from 34,000 tons hoisted, against 35,000 tons hoisted the previous month. The yield in 1906 was 28.32 lb. and has been receding to an average of 24.75 lb. for the year ended June 30. The Stanton management estimated a life of from 20 to 25 years remaining. The Finlay report, based on an average annual production of 9,000,000 lb., estimates its life at nine years.

MINNESOTA

St. Louis County

(Special Correspondence.)—At the invitation of the School of Mines Alumni Association, George E. Vincent, president of the University of Minnesota, members of the Board of Regents, Deans and Faculty members of the Minnesota School of Mines and Engineering Colleges, made a trip over the Mesabi range, August 11 and 12. After looking over the Fayal mine at Eveleth, the party was taken in ten automobiles to Virginia and Hibbing. At Hibbing, the Oliver Iron M. Co.'s famous 'seeing the mines' cars were placed at the disposal of the visitors, and the Hull, Rust, and Mahoning mines were visited. After the sight-seeing tour, a general reception was held at the Oliver Club and the club parlors were filled with people. Frank A. Wiles, State Inspector of Mines, delivered the address of welcome. After speeches by members of the Board of Regents and others, Mr. Vincent responded with one of his characteristic addresses in a way that pleased the hearts of all who heard him. Mr. Vincent feels that he has accumulated something worth while by his visit, having seen the largest iron mining operations in the world and incidentally met the prominent mining men on the range.

Hibbing, September 1.

MISSOURI

Jasper County

The Golden Rule Zinc & Lead Co., capitalized at $8000, has been formed to develop the old Lincoln mine northwest of Joplin.

W. S. Brown, State Mine Inspector, has petitioned the Circuit Court for an injunction against mining operations being done by Thor Relling and A. G. Dixon in a mine near Chitwood. He alleges the drifts are cut too wide and that there is only one shaft. The injunction is asked under a law empowering mine inspectors to close such mines when petitioned by persons employed there on the ground that the mine is unsafe. It is said other mines have similar conditions, but have two shafts to provide escape in case of cave-ins.

Newton County

The Lion M. & M. Co. will have a 100-ton mill, if present plans are carried out, on its property at Seneca. The work heretofore has been done with a hand-jig. Lead, blende, mundic, and silicate are found in large quantities. F. V. Wasserman is in charge.

Development in the Saginaw, Missouri, camp, is attracting attention. Recent discoveries of rich 'chunk' lead, occurring near the surface, have spurred prospectors to activity, and more than a dozen new shafts are being sunk on the St. Paul Mining Co.'s land, the Saginaw Investment Co.'s land, and on various farms in that vicinity. Among the richest strikes was that made by D. O. Neely on the St. Paul property. Neely employs two men and labors himself, and his weekly profits range from $50 to $75.

MONTANA

Lincoln County

(Special Correspondence.)—Negotiations are in progress here on a deal which means that the Howard placers, south of Libby, will be operated on a large scale. W. Dickerson, a mining engineer of Helena, has completed a thorough examination of the property, which consists of 840 acres of land near Howard lake. If the deal goes through, which now seems almost sure, a large hydraulic plant will be put in at once. Arrangements have already been made with J. Y. Ownbey and G. F. Hinton to take their steam drilling machine to the property and prospect it thoroughly. The drill is now being operated on the Criderman-Town placers, upon which it is proposed to install a dredge.

It is reported that a find of good ore has been made in the Victor-Empire mine on Granite creek, twelve miles from town.

The owners of the Big Eight mine, near Troy, are building a road from the mine to connect with the county road, preparatory to beginning operations. There is now on hand about 100 tons of shipping ore ready to be sent to the smelter. The vein is about 6 ft. wide, with about 3 ft. of shipping ore, and has been extensively developed. The ore is mostly zinc.

Libby, September 1.

Silverbow County

Five miners were killed in the shaft of the Black Rock mine of the Butte Superior company last Sunday, while riding upon the cage when it was being used to haul dull steel to the surface. It is thought that their crowding dislodged the steel. The men were fearfully cut and their bodies were swept into the sump. Riding on the cage at the time was in violation of orders. The men thought to save time in reaching the surface.

The Butte Central's Ophir shaft is passing through a large vein at a depth of 950 ft., state press reports, fulfilling Superintendent McConnell's forecast of a year ago that the vein would be found at a depth of about 1000 ft. He believes that it is the Rarus fault fissure, running northeast and southwest through the district, and that it will be rich in the Ophir ground.

VIEW OF BUTTE, MONTANA.

(Special Correspondence.)—Some of the independent mine owners have been in consultation recently considering a proposition to invest a considerable amount of money in the East Butte company with a view to having the company enlarge the Pittsmont smelter for the treatment of the ore of all independent companies. This is a substitute scheme which has been started up in place of the one proposed more than a year ago to build an independent smelter. Among the mine owners there seems to be some intimation that any reasonable proposition backed financially will be well received by the East Butte people, but those who are promoting the movement in Butte will not go into details. One of the independent mine owners said that the Washoe smelter and the Pittsburg smelter were giving every satisfaction in the treatment of custom ores, but that there was a fear that should the mines belonging to the companies controlling the smelters increase to their full capacities, the custom ores might not receive the attention they are getting now, and therefore it was deemed advisable to be prepared for the emergency. When asked if the Butte-Alex Scott company had been invited to join in the movement for the independent smelter, Mr. Hugo said that while he had heard of the scheme proposed, his company had not been officially approached. "However," he said, "if the scheme goes through I guess we will join with the rest of the companies." At the present time the only independent mines producing any copper are the Tuolumne, the Elm Orlu, the Poser, and the Butte-Alex Scott. The Tuolumne is at present sending its ore to the Washoe under a contract which expires next spring, while the ore from the Poser and Elm Orlu is also going to the same smelter. While the latter is W. A. Clark's zinc property it has of late been hoisting considerable copper ore. The Butte-Ballaklava and the Pilot Butte are among the properties expected to join the producing class by next year. The East Butte is, of course, in the producing class, but the company owns the Pittsmont smelter and therefore is not taken into account when considering the mines likely to go into the agreement to enlarge the Pittsmont and subscribe for a certain amount of stock.

Butte, September 2.

NEVADA

Esmeralda County

(Special Correspondence.)—The Goldfield Con. M. Co.'s net yield for July was $582,021, about $19.89 per ton, from a production of $848,129, an average of $29 per ton. The net recovery averaged $27.42 per ton, and the cost of production $7.66 per ton. During the month 29,253 tons of ore was milled, against 28,540 in June, and 29,150 tons in May. The development work for the month amounted to 4078 feet.

(Special Correspondence.)—The Goldfield Con. M. Co., at its quarterly meeting at San Francisco, August 31, declared a regular dividend of 30c. per share and an extra dividend of 20c. per share, payable October 31 to stockholders of record on September 30.

Goldfield, September 4.

(Special Correspondence.)—The Milwaukee Gold & Copper Co., capitalized at $1,500,000, has been organized to develop three claims 15 miles south of Goldfield. The property has a 160-ft. shaft. J. W. Evans, of Goldfield, is president and general manager.

Goldfield, September 2.

Humboldt County

A pair of bandits recently held up men guarding high-grade ore in the assay office of the Mammoth mine at National and stole $3000 worth of ore. One of the outlaws was wounded. The ore subsequently was recovered.

Orson Smith, general manager of the Utah Nat. Dev. Co.'s property at National, is quoted in the press as stating that the company has taken over the claims, which consist of 60 acres adjoining the Mammoth and Birthday. The property is known as the Shiloh group. It has been operated by the Utah Nat. Dev. Co. for the last six months under lease and bond.

Nye County

A part clean-up was made last week at the War Eagle mill, about 1000 tons having been treated. Two bars of gold bullion weighing 46½ lb. avoirdupois, and an 11-lb. bar shipped the previous week make a total production of 838.35 oz. troy, valued at $11,653. The returns from the zinc precipitate sent to the Selby smelter have not been received. It is estimated that the mill-run will amount to 1800 tons, according to late newspaper statements.

The Tonopah-Belmont Dev. Co. has declared a dividend of 25%, payable October 2 to stockholders of record on September 15.

Storey County

The assessment list for the Comstock mines, as announced in San Francisco September 5, is as follows: Challenge, No. 56, July 15, 5c.; Savage, No. 21, July 17, 10c; Hale & Norcross, No. 28, July 28, 5c; Best & Belcher, No. 96, July 31, 5c.; Overman, No. 36, August 7, 5c.; Con. Virginia, No. 18, August 9, 25c.; Exchequer, No. 20, August 15, 5 cents.

White Pine County

Four units of the Steptoe concentrator at McGill have been closed on account of lack of water, and work probably will not be resumed until the fall rains start.

The Giroux Con. M. Co. has been delayed in making ore shipments, it is reported, through the failure to obtain favorable rates from the Nevada Northern to the Tooele smelter. The recent rate decision of the Interstate Commerce Commission, it is said, is effective only to Cobre on the Southern Pacific, and does not affect the rates on the Nevada Northern. The Giroux shaft will reach the 1600-ft. level before the new year. A large station will be cut there. About 75 men are employed.

(Special Correspondence.)—The Giroux shaft, in which a fire occurred August 23 with the result of the death of seven miners, was opened last week and the body of Dan Drea, which was in the mine when the shaft was sealed, was recovered. The damage to the shaft is reported to be comparatively slight.

Ely, September 4.

NORTH CAROLINA

Montgomery County

(Special Correspondence.)—The Uwarra Mine Co. has been formed, as a reorganization of the Montgomery M. Co., and the mine, which has been idle for some time, has been pumped out. The 10-stamp amalgamation mill on the property will be enlarged. Percy E. Barbour is manager for the company.

Candor, September 2.

WASHINGTON

Ferry County

(Special Correspondence.)—The Ben Hur Leasing Co. has laid off some men, being short of water to run the steam boilers. The usual supply is piped from Mud lake, but the piping has been choked by water snakes. At the Black Tail mine the Hope company has sunk the shaft on the cross-vein 38 ft. From off the winze, on the 300-ft. level, the drift on the east-west vein is in 40 ft., being run in the foot wall, to avoid taking out ore until the Granby smelter resumes operation. The last sample assayed $33 per ton and the last previous to that one assayed $43.90 per ton. The San Poil Con. company has laid off several men, as the smelters have quit buying custom ore for the present. The Rathfon Reduction Works has received a vanner table, for use in the cyaniding plant. At the North Washington Power & Reduction Co.'s mill operations have been again delayed for want of lumber.

Republic, September 2.

CANADA

British Columbia

The Hall mines smelter, the well known plant at Nelson, was destroyed by an incendiary. The loss is about $350,000. The plant had been idle for some time. A dozen other fires, which destroyed the brewery and other structures, are believed to be the work of the same man.

Ontario

The Jowsey-Wood claims, near the three-mile post on the base-line of Carscallen and Denton, have been acquired by A. D. Miles, consulting engineer for the Canadian Copper Co. Through the seven claims runs a rich quartz dike with a showing of free gold. Assays range from $93 to $224 per ton. The price is reported to have been $250,000.

It is reported that a survey party at the Big Dome recently discovered an unusually rich vein, the showing being slightly over 2 in. wide and 18 in. long. The vein has been stripped for 125 ft. The slab first discovered is reported in the newspapers as being nearly solid gold and will be exhibited in various cities. During prospecting at North Dome a vein was discovered which is said to assay over $2900 per ton. The vein was concealed by a slate capping and is believed to overlie rich sulphides.

N. L. Griswold, a mining man of New York, has acquired the Vendetta, Legree, and Kirkland claims in Carman, Porcupine district. They are a mile from Nighthawk lake. Assays run from $5 to $30.

(Special Correspondence.)—Late reports of the recent discovery of high-grade gold ore on the North Dome are that the vein has been uncovered for 50 ft. and is from 6 to 7 ft. wide between well defined walls. The vein when first sampled assayed at $2932 per ton.

Porcupine, September 2.

JAPAN

With a production for 1910 of over 100,000,000 lb. of copper, Japan scored a record, states the *Boston News Bureau.* The leader was the Ashio mine, with 19,500,000 lb. of copper. Sixteen mines had a production of more than 1,000,000 lb. each, and a combined production of 101,602,616 lb., against 80,313,051 lb. in 1909.

PHILIPPINE ISLANDS

(Special Correspondence.)—A deal for 1000 acres of dredging ground in the Paracale district was closed in July. The purchasers are capitalists from Melbourne, Australia.

Manila, July 25.

Company Reports

AMERICAN SMELTING & REFINING COMPANY.

The twelfth annual report of this company, for the year ended April 30, 1911, shows that the net earnings from the operation of smelting and refining plants was $7,600,931; to which must be added earnings from mines owned by the company, amounting to $331,334; miscellaneous earnings amounting to $243,218; income from investments amounting to $2500; and interest and commission, $577,697. From this total must be deducted ordinary repairs and replacements, $862,710; corporate and excise taxes, $9977; administrative expense, $375,076; and depreciation credited to property account, $461,638, leaving a net income of $7,046,278. Dividends amounting to $5,500,000 were paid, and the balance, $1,546,278, was transferred to profit and loss account. During the year 122,490 shares of common stock of the American Smelters Securities Co. were acquired; all the common stock of this company is now held by the A. S. & R. Co., and is carried upon its books at a valuation of $60 per share, or a total of $18,000,000. During the year the outstanding preferred shares of the United States Zinc Co. were also acquired and the entire stock, both common and preferred, is now held by the A. S. & R. Co. Similarly, the stock and bonds of the National Metallurgical Co. of Mexico were acquired and all but unimportant amounts are now held. The last payment of $131,000 upon the bonds of the Omaha & Grant Smelting Co. was made during the year and the issue is now completely retired. January 5, 1911, an increase in the common capital stock of the A. S. & R. Co. from $50,000,000 to $65,000,000 was authorized by the shareholders. The American Smelters Securities Co. has issued $15,000,000 of 6% 15-year gold debenture bonds which are convertible into common shares of the American Smelting & Refining Co.; this entire issue has been acquired by the A. S. & R. Co., the A. S. S. Co. thus repaying advances made to it and discharging its floating indebtedness. Through this transaction it is expected that the A. S. & R. Co. will eventually receive $15,000,000 additional cash capital, which added to the present cash capital will make a total of $27,000,000. The ores and metals in process of smelting, supplies on hand, and investments, represent a total of $23,000,000, so that the preferred stock of the company thus has its face value offset by cash and quick assets. The common stock is represented by property to the value of $86,000,000 and $17,751,000, par value, of common shares of the American Smelters Securities Co. The bonds mentioned above are convertible, at any time prior to 1918, into common shares of the A. S. & R. Co., at par, and after February 1, 1915, are subject to redemption.

The mines owned by the company are in Mexico and are operated to assure the necessary supply of ore to the smelter at all times. The profits of these mines are credited to the purchase price and development expense until these are liquidated, after which the profits are credited to surplus, $105,618 having been so credited during the year. As these mines are not carried upon the books of the company as an asset, no provision need be made for depreciation. Metals in process of treatment are inventoried at fixed prices, 50c. per ounce for silver, 12c. per pound for copper, and 3.8c. per pound for domestic lead. The profits of the company are a commission upon the metals bought and sold by the company. There is paid to the mines the daily market price of the metals in the ores bought, the only fixed factor being the working charge, which is made sufficient to cover the smelting, refining, transportation, and profit. The company therefore acts virtually as the agent of the mines. The ordinary net income of the company during the year under review was approximately the same as the preceding year, though this period was one of business depression and restricted consumption. The smelting capacity of the various plants owned by the company is now 5,500,000 tons per annum, the refining capacity 460,000 tons per annum, and through its connection with the American Smelters Securities Co. it has an additional interest in a smelting capacity of 2,650,000 and a refining capacity of 190,000.

Decisions Relating to Mining

Specially reported for the MINING AND SCIENTIFIC PRESS.

CONVEYANCE OF MINERAL RIGHTS BY PERSON IN ADVERSE POSSESSION

The mere execution of a deed by one in the adverse possession of coal land and mineral rights therein does not operate as an abandonment of the possession. Until he does some act of surrendering the possession, he is regarded by the law not as abandoning the possession, but as holding the possession for the benefit of the grantee as his tenant at sufferance. And such conveyance does not operate as a severance of the estates of the surface, or agricultural rights, from the mineral rights.

Black Warrior Coal Co. *v.* West, (Ala.) 54 Southern, 200. Jan. 1911.

RECOVERY OF VALUE OF ORE CONVERTED—PROOF

In an action against a mining company to recover for ore mined by it and converted to its own use, from a vein owned by the plaintiff, proof of the value of similar ore taken from the same vein nearby is admissible on the part of the plaintiff, as a method of proving the value of that converted by the defendant. The reason of the rule is that it is within the power of the defendant to show the actual value of the ore taken if that shown by the plaintiff's evidence is excessive. The measure of damages in such case is the amount which will compensate for all the detriment proximately caused thereby, and the detriment caused by the wrongful conversion of personal property is presumed to be the value of the property at the time of its conversion with interest from that time.

Montana Mining Co. *v.* St. Louis Mining & Milling Co., 183 Federal, 51. Oct. 1910.

ASSESSMENT OF MINING CLAIM FOR DAMAGES

Where the locator of an unpatented mining claim uses the surface for townsite and building purposes, it may be assessed for taxes and such assessment is on use of the ground for the town site and building purposes, and not on an unpatented mining claim. And a decree of the court enjoining the collection of taxes on the parcel of ground designated as a mining claim until the claim is purchased from the Government, on a complaint alleging that the assessment was unlawful because the legal title was in the United States, merely adjudges the mining claim as such, not subject to taxation because the legal title was in the United States, but does not determine and settle the question of the right to tax the surface ground where it is used and as a separate and independent value for other than mining purposes.

Cobban *v.* Meagher, (Mont.) 113 Pacific, 290. Jan. 1911.

RIGHT OF CREDITOR TO EXAMINE AND INSPECT MINING PROPERTY PRIOR TO EXECUTION SALE

A judgment creditor has no right to an order permitting him to examine and inspect mining property, though he has caused an execution to issue against the debtor and to be levied upon his property. To enable a person to make an examination of mining property for the purpose of protecting and preserving his possession, title or interest therein, it is necessary for him to allege and show a bona fide claim to possession, title to, or interest in the property sought to be examined and inspected, or otherwise the court has no jurisdiction to make an order giving him such permission. And a judgment creditor has no such interest in property levied upon and does not show any necessity for the granting of an order permitting him to examine and inspect the property levied upon prior to the execution sale. In such case the claim to possession, or title to, or interest in, a mining claim must be an actual right, and real interest.

Bacon *v.* Federal Mining & Smelting Co., (Idaho) 112 Pacific, 1055. Dec. 1910.

Book Reviews

Any of the books noticed in these columns are for sale by, or can be procured from, the MINING AND SCIENTIFIC PRESS.

OIL FUEL. By Sidney H. North, revised by Edward Butler. Pp 248, Ill., index. Charles Griffin & Co., Ltd., London, 1911. Price $2. For sale by the *Mining and Scientific Press*.

This is a new edition of a standard work well known and highly valued. It covers the supply, composition, and application of oil fuel and has been substantially enlarged since the appearance of the first edition in 1905. While the book deals with European conditions and practice it contains much of value everywhere.

THE MINERAL INDUSTRY, 1910. Edited by Albert H. Fay. Vol. XIX. Pp. 904, Ill., index. McGraw-Hill Book Co., New York, 1911. Price $10. For sale by the *Mining and Scientific Press*.

This indispensable annual follows in style the preceding volumes of the series with reviews for each mineral and revised statistics. The special chapters are: 'Sulphur Smoke in Metallurgical Works,' by Herbert Lang; 'Dredging'; 'Mining Practice in 1910,' by Albert H. Fay; 'Propress in Ore Dressing and Coal Washing in 1910,' by Robert H. Richards and Charles E. Locke; and 'Assaying and Sampling,' by Donald M. Liddell.

PUMPING MACHINERY. By A. M. Greene, Jr. Pp. 703, Ill., index. John Wiley & Sons, New York, 1911. Price $4. For sale by the *Mining and Scientific Press*.

This is a treatise on the history, design, construction, and operation of various forms of pumps and is the outgrowth of a course of lectures which is given as one of the required courses to students of mechanical engineering at the University of Missouri. While intended for the use of those who have studied hydraulics, mechanics, and the strength of materials, its usefulness is by no means limited to such persons. The elements of pumps for all purposes are given and the principle available types are described. The book forms an excellent basis for a study of pumps. If it could be supplemented by another on operation a marked gap in existing engineering literature would be closed.

Recent Publications

COMPOSITION OF TEXAS COALS AND LIGNITES, AND THE USE OF PRODUCER GAS IN TEXAS. By Wm. B. Phillips, S. H. Worrell, and Drury McN. Phillips. Bull. Univ. Texas, 189. P. 134. Austin, 1911. A general report prepared by the Bureau of Economic Geology and Technology, of the University.

ADVANTAGES OF MAINE FOR ELECTROCHEMICAL INDUSTRIES. By C. Vey Holman. Reprint from Trans. Amer. Electrochem. Soc., Vol. XIX, 1911. 8 pp. Attention is called to favorable geographical situation as regards transportation, to abundant water-power, and to undeveloped minerals.

THE UNITED STATES GEOLOGICAL SURVEY has recently distributed the following new publications: Foxbury-Clarion Folio, Pennsylvania, by E. W. Shaw and M. J. Munn; The Mount McKinley Region, Alaska, by Alfred H. Brooks, Prof. Paper No. 70, pp. 234, ill., index, maps; Water Supply Papers 267, 268, 273; Mineral Resources of the United States, 1909, part 1, Metals, part 2, Non-Metals (bound volumes); Mineral Resources, 1910, separates, Barytes, and Strontium, by E. F. Burchard, Coke, by E. W. Parker, Anthracite Coal, by E. W. Parker, Phosphate Rock, by F. B. Van Horn, Talc and Soapstone, by J. S. Diller, Bauxite and Aluminum, by W. C. Phalen, Mineral Paints, by E. F. Burchard, Peat, by Charles A. Davis; Results of Spirit Leveling in West Virginia in 1909 and 1910, Bull. 477, 54 pp.; Results of Spirit Leveling in Texas, Bull. 468, 127 pages.

Personal

Professional men are invited to send news of their engagements and travels. Such news is interesting to friends.

E. R. BUCKLEY is in Montana.

F. B. WEEKS was in San Francisco recently.

M. K. RODGERS was in San Francisco this week.

THOMAS KIDDIE was in San Francisco last week.

K. P. SWENSON has been visiting Manchurian mines.

W. F. ENGLEBRIGHT visited San Francisco last week.

L. J. REYERSBACK was in San Francisco over Sunday.

ERNEST LEVY has returned to Rossland, B. C., from London.

F. A. SIZER returned to San Francisco from Grass Valley Monday.

GEORGE OTIS SMITH will attend the A. I. M. E. meeting at San Francisco.

R. Y. HANLON is in Korea examining placer deposits for Australian investors.

S. J. WEIS, who has been on the West African gold coast, is visiting San Francisco.

PERCY E. BARBOUR is manager for the Uwarra Mines Co., at Candor, North Carolina.

R. H. ERNEST, superintendent for the Round Mountain M. Co., is visiting San Francisco and Los Angeles.

RAYMOND C. BENNER has gone to the University of Pittsburg to study the smoke problem with R. K. DUNCAN.

WILBUR A. HENDRYX has gone to London, from which point he will sail for South Africa to erect a Hendryx plant on the Rand.

W. KAEDING has been appointed superintendent of surface departments for the Consolidated Mines Co. at Goldfield, Nevada.

LEO F. ARNOLD has resigned as general superintendent for the Casa Diablo G. M. Co., at Bishop, California, and returned to Chicago.

FAYETTE A. JONES has severed his connection as consulting engineer for the Oriole Gold Mining Co., and is now in British Columbia.

L. D. HUNTOON has resigned from the Sheffield Scientific School and opened an office at 42 Broadway, New York, for practice in mining engineering.

EDWARD M. RABB, JR., has resigned as chief engineer for the Moctezuma Copper Co., and will be engaged in professional work with headquarters at 3535 W. 24th avenue, Denver, Colorado.

WILLIAM T. MCDONALD, who has been acting as assistant superintendent of the Magna plant of the Utah Copper Co., has been appointed superintendent of the Chino mill, and will leave shortly to take up his new duties.

Information is desired regarding BARTHOLOMEW SWIFT, a native of Ireland, born about 1846. He is supposed to have worked in the mines of the Pacific Coast for several years, and was in San Francisco prior to 1901. Property belonging to him is unclaimed.

RALPH D. BROWN has been appointed instructor in civil engineering at the Missouri School of Mines. Mr. Brown is a graduate of Miami University and of the civil engineering department of the University of Ohio. Since 1909 he has been in the employ of the O'Gara Coal Co. at Harrisburg, Illinois, as assistant engineer.

SIDNEY S. SCHMIDT, a graduate of the Missouri School of Mines, and at present a chemist at the Washoe smelter at Anaconda, Montana, has been appointed assistant in mineralogy at Northwestern University. He will take the place of A. J. ELLIS, who resigned to accept an appointment on the United States Geological Survey.

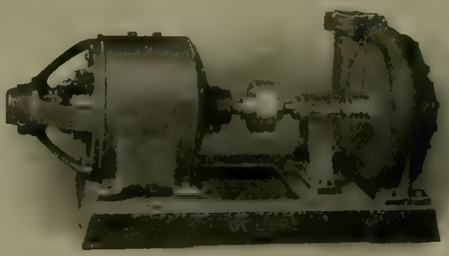
A New Line of Centrifugal Pumps

The Goulds Manufacturing Co. of Seneca Falls, New York, has just placed on the market an entirely new and improved line of centrifugal pumps. These are furnished in both the single-stage single-suction, and the single-stage double-suction types. Either type may be arranged for belt-drive or direct connection to electric motor, gas, gasoline, or steam-engine, steam or hydraulic turbines. The single-suction, as well as the double-suction pumps, contain many special features, which are described below.

The impeller in the single-suction pump is of the open type. The vanes are carefully designed so that the maximum efficiency is obtained over normal conditions. The impeller is accurately machined to minimize the clearances between the impeller and the side covers. This has considerable influence upon the high efficiency which is obtained with this type of pump. Although of the single-suction type, which in most cases means a considerable amount of end-thrust, the impeller in the Goulds pump is designed in such a manner that this annoying feature is entirely eliminated. The stuffing-box through which the shaft passes, has a brass water-sealing ring which prevents air being drawn into the pump. Air will destroy the vacuum in a pump and impair suction.

SINGLE-STAGE DOUBLE-SUCTION GOULDS CENTRIFUGAL PUMP WITH CASE OPEN.



SINGLE-STAGE SINGLE-SUCTION GOULDS CENTRIFUGAL PUMP, DIRECT CONNECTED TO ELECTRIC MOTOR.

The single-stage double-suction centrifugal pumps are designed with a view to combining all mechanical details necessary to produce a centrifugal pump of the highest grade. The casting proper consists of two pieces bolted together on a horizontal joint. The purpose of dividing the casing is to permit quick and ready access to the interior of the pump for inspection without disturbing the pipe connections. The impeller is of the most modern enclosed type and develops the highest efficiency under the conditions for which the pump is sold. The bearings are of the ring-oiling type, independent of the stuffing-boxes, and they are provided with removable shells lined with the best quality of anti-friction metal. The stuffing-boxes are provided with brass water-sealing rings. The double-suction pumps are sold for heads up to 150 ft., while the single-suction pumps operate against maximum heads of 100 ft. The illustrations show one of the single-suction pumps direct connected to an electric motor and a view of the double-suction pump with the upper half of the casing partly removed.

ENGINEERS interested in various phases of lighting problems will meet at Chicago, September 25 to 28, when the Illuminating Engineering Society will be in session. The program, however, is far from being light.

IDLE CARS afford a good index to current business, and, amid all the signs of discouragement now current, it is worth noting that on the first of August the number idle was less than at any time since the first of this year.

LARGEST production does not necessarily mean largest dividends. In 1910 the Amalgamated Copper Company produced 233,808,546 pounds of copper and paid $3,065,750 in dividends. Phelps, Dodge & Company produced 116,888,000 pounds, paying $4,500,000, while the record of the Utah Copper Company was 84,502,475 pounds and $4,619,000 dividends.

ACTION is being taken to clear up existing claims in the Matanuska as well as the Bering River coalfields. Mr. A. C. Frost of Chicago and his associates, among whom we note the name of Mr. Bion J. Arnold, have been cited to show cause why their claims should not be cancelled. Mr. Frost proved to be an adroit promoter in connection with the Chicago & Milwaukee Electric railway and entangled a number of excellent men.

SALE of the Golden Gate mine of Chichagof island near Sitka, Alaska, to the DeGraff Mining Company is announced. This brings under one management two neighboring mines that, while small, have been unusually profitable. The Golden Gate is reported to have approximately 125,000 tons of ore worth $14 per ton in reserve, with excellent prospects of more being developed. The vein is well defined and the ore is easily treated. Doubtless now that the two mines are owned by one company a large mill will be built.

GOOD progress is being made in preparing for smelting at the Hidden Creek mine on Observatory Inlet, British Columbia. It is estimated that 12,000,000 tons of ore containing 1½ to 3 per cent copper is available here, and the plan of treatment involves direct smelting. It is so common to hear of large milling operations in connection with the copper mines now being opened that the fact that mills are unnecessary at some is overlooked. The new property of the Granby company is fortunately in the class that requires no mill. Record low costs are anticipated.

DURING the six months ended July 30, 1910, the Balaklala Consolidated Copper Company paid $42,233 in settlement of claims for smoke damages. During the last year and a half that the company operated, its plant at Coram was closed three times in connection with the erection of the Cottrell equipment and ran at about one-third capacity between times. The precipitating apparatus was built at a cost of $107,589. The Balaklala ore is of low grade, containing approximately a dollar per ton in gold and silver and about 2½ per cent of copper. Despite the low price of metal and other discouragements the company earned $127,326 in the period mentioned. This indicates unusually good technical work, and, in fact, the plant is known to have made a record in pyritic smelting, though no details are available.

AUSTRALIAN copper production in the first seven months of 1911 amounted to 32,668,240 pounds, as against 29,500,000 pounds in the corresponding months of 1910. The Mt. Elliott property was forced temporarily to suspend operations, but the other great properties produced as follows: Mt. Morgan, 9,546,880; Mt. Lyell, 10,056,160; Great Cobar, 9,662,640; Great Fitzroy, 3,402,560 pounds. This copper no longer comes to the United States to be refined, but is now handled by the Electrolytic Refining Company of Australia, a concern controlled by L. Vogelstein & Co. Formerly Australian copper was an important factor in keeping up the refinery output of the Atlantic States.

UNUSUAL occupations, as exhibited in recent census reports, are discussed by a daily contemporary. We note with interest 'dock walloper,' 'scabber,' 'flosser,' and 'dubber,' but the list is evidently incomplete, for 'scrammer' is omitted. In the Lake Superior iron region where caving methods are extensively employed, the miners say that it is necessary to serve a long apprenticeship as an ordinary miner before becoming a qualified 'scrammer.' It is interesting to note also that the method, which appears to have no distinctive name other than this colloquial one, is now being applied to the mining of a large body of low-grade copper ore in the Ohio mine at Bingham, Utah, at a cost unofficially stated at 35 cents per ton.

EXISTING rights in Mexico are promised scrupulous protection in a letter written by Mr. Francisco I. Madero recently. There have been intimations that Mr. Madero occupied close relations to the Standard Oil Company, and that in fact the revolution in Mexico was but an after effect of the war between the Waters-Pierce and the Pearson oil interests. Lord Cowdray called upon Mr. Madero to discuss the matter and was assured in positive terms that he would use all his undoubted influence to prevent any change in the settled Mexican policy of exact fulfillment of any guarantees given foreign companies, and also that he would welcome further investment of foreign capital. This was to have been expected, but this explicit statement is none the less gratifying.

ECONOMY results from the introduction of petroleum as fuel on shipboard, not only because of the greater calorific power of the fuel, but because of incidental savings. When the steamship *Mariposa,* running between San Francisco and Tahiti was changed to an oil-burner, a reduction of 16 men was made in the engine-room force. The *Mauretania* carries 312 firemen, whereas it is estimated that if oil were burned, not more than 30 would be needed. The extra men require wages, food, and room, all of which are important on shipboard. Oil fuel requires less space per heat unit than does even the best coal, and 36 cubic feet of oil is equivalent to 67 cubic feet of coal as usually stored in ship bunkers. The ships burning oil have larger cargo space available. In the case of warships this permits heavier guns or a longer steaming radius, either of which might prove decisive in a great national crisis. The Liquid Fuel Board which in 1902 studied the problems of oil fuel for the navy reported adversely on the ground of the limited supply of petroleum available. Since that time, however, the annual output of the United States has practically doubled, and adequate supplies are now available on both coasts. Oil is being introduced on some of the warships and an increasing number are likely to be equipped for its use.

CRITICISM has been leveled at Bewick, Moreing & Company for having sold its interest in the Hollinger mine almost as soon as it was acquired. The fact seems to be that the announcement that the firm had purchased the property sent the shares up so rapidly that there was more profit in selling than in holding them. The firm accordingly sold, and thereby realized the money needed to finance its other ventures at Porcupine. The net result is that speculators have furnished Bewick, Moreing & Company with approximately a half million dollars and that this money will be spent in testing additional ground.

PLANS are being discussed at Cripple Creek, Colorado, to prevent the Western Federation of Labor from regaining a foothold in the district and for control of ore-stealing. Unfortunately the two go together at Cripple Creek. There, as in San Francisco and at a number of other points, the good cause of union labor is being used to advance the personal fortunes of men of no character. Doubtless in time the miners' union will obtain a standing corresponding to that of the Brotherhood of Locomotive Engineers and other reputable organizations. It will not do so, however, until its character and leaders warrant the same measure of respect. The more rapidly it can be accomplished the better it will be for the industry.

Industry and Art

A recent volume published in Munich bears the depressing title *'Die Kunst Stirbt.'* It is discouraging to have the demise of art announced from the city generally regarded as its chief place of abode, and we would be correspondingly grief-stricken were it not that the arguments which the author advances to prove that modern progress has slain artistic ideals awake vague reminiscences of the Latin and Greek poets who mourned the passing of the Golden Age some two thousand years ago. It is quite true that the dreamer needs to look out that the advance of industry does not overrun him; this has always been true, but that there is now less opportunity for the play of imagination is the reverse of true. Romance has its proper environment; only when we try to mix it with reinforced concrete we get an unsatisfactory product. Once mankind had little more than romance, ideals, and a bare living. Now the average man has so much more than a bare living that material comforts bulk larger in the scheme of living than was once the case. Art is capable of larger things nowadays and the skill that once exhibited itself in the painting of miniatures now has opportunity to display itself in the control of energy so adroitly that a giant crane deposits a twenty-five ton casting in its place as accurately as a jeweler adjusts a watch. Recently we referred to the dramatic aspects of steam-shovel work in mining—some twenty shovels at work both in the sunshine and under the glare of searchlights at night, stripping bare the mountainside at the rate of fifty thousand tons a day and exposing workings but a short while since slowly conducted with much effort in the depth of the mine. Most men take such achievement much as a matter of course nowadays—no one has written an epic poem on the Panama canal, yet as an example of great human achievement it far outranks the subject of many a great poem. And this leads us to the explanation. Where once a few men led lives of achievement, full of romance, a few others wrote songs about them, and most people were perforce content to merely hear about the deeds of others, now a life of achievement and romance is within the reach of the average man. Naturally he prefers his romance first hand, and the trade of the singer has declined. Art is not dead; rather men prefer to live art than to see art or to hear art. And who can say we are not the gainers thereby?

A First Step in the Solution of the Alaskan Problem

AN EDITORIAL SUGGESTION

That present conditions in Alaskan coalfields are extremely unsatisfactory is widely recognized. Large areas of excellent coal within a few miles of tidewater remain unopened, while railroads and other enterprises import coal at a cost of $7 to $9 per ton on the dock. In the interior, the price of coal is practically prohibitory, and development of any industry requiring handling of large tonnages is impossible except at the seacoast. Industry in Alaska always will be at a disadvantage owing to the difficulties and expense of navigation along its coasts, and of transportation into the interior. This, however, is all the more reason why full advantage should be taken of any favorable local feature, such as abundant and excellent coal.

In examining the matter of the opening of the Alaska coalfields, two distinct questions must be considered. The first, and more pressing, is, how to get coal on the market quickly in quantities sufficient to satisfy immediate demands. The second is, what disposition shall ultimately be made of the coal lands, and under what condition coal shall be mined in the future. Both questions involve railway problems and are complicated by existing rights of coal-land locators. It is extremely unlikely that any satisfactory solution of the second problem will be found immediately, and we have no desire to discuss it at the present time. The ramifications of the matter reach such varied interests, and so many things must be taken into account, that a quick determination might well prove a wrong determination. The first problem, however, that of promptly furnishing Alaskan coal in such quantity as is really needed, seems to us capable of speedy and safe solution.

It has been estimated by Mr. A. H. Brooks that there is a present potential market for 1,000,000 tons of Alaska coal per year. Whether or not we agree that these figures are correct, it is undoubtedly true that there is an important market awaiting the opening of the mines. At present all the high-grade coal used on the Pacific Coast comes from the East or is imported. The Navy, for strategical reasons, uses only the best grade of Pocahontas coal, and when the fleet goes to sea it is followed or preceded by a long string of colliers carrying Eastern coal. At all times there is a procession of boats traveling around South America in order that the battleships and cruisers shall have smokeless coal. Necessarily much coal is burned in bringing this fuel to the ships, and, necessarily also, the cost of the coal delivered is greatly above that at Eastern tidewater ports where it has already been raised by the several hundred miles of railway haul from the mines. In case of war, the supplying of ships in the Pacific with Eastern fuel would be extremely difficult and expensive. Even now the Navy is dependent upon foreign tramp steamers. So far it has not seemed wise to convert the whole fleet into oil-burning vessels, because of the difficulty of buying oil in foreign ports. In the opinion of experts, the Bering River coalfield of Alaska can furnish a grade of coal excellently adapted to naval use, and the opening of mines there is important in order to afford an adequate and at all times accessible source of supply. The Navy uses ordinarily about 150,000 tons of coal per year on the Pacific Coast. Possibly the other departments of the Government use as much more. In addition, there is a local market in Alaska now supplied from British Columbia and Washington at considerable expense. Beyond is a strongly competitive market in which the dominating features are the abundance, low price, and high heating value of California crude oil. In the three Pacific States together, in 1910, imports and local production of coal amounted to 1,600,000 tons. Mr. E. W. Parker has estimated that in the same year fuel oil displaced 12,000,000 tons of coal in these States. To what extent Alaska coal can enter this competitive market is uncertain, but the non-competitive market is not unimportant alone. In it, owing to naval requirements, the Government is the largest factor. The obvious thing to do would seem to be for the Government to open its own mine and supply its own coal, at the same time meeting the local demands of the non-competitive market by selling the surplus coal at a small advance on the cost of production. The opening of a mine by the Government in no way prejudices any future settlement of the larger problem of final disposition of the lands. It will, however, remove any fancied necessity for a hurried decision of the main matter, will relieve the local fuel situation, will lead to just as much development and the employment of just as many men, as if some private syndicate undertook the work, and it will permit the Government finally to act on the larger questions involved with exact knowledge based upon actual experience under the conditions to be met. It has long been customary for large coal users to maintain a coal mine or to have an interest in a coal mining company so as to have full information regarding costs when making their yearly contracts. For years the Chicago, Milwaukee & St. Paul railroad ran a small coal mine on this basis, and the information it obtained was worth many times the risk of loss. Why should not the Government safeguard the people's interest as carefully as a board of directors for a company looks after those of the stockholders?

Various suggestions have already been made as to how the Government should proceed in case it be decided to open a Government mine in Alaska. An independent commission has been proposed, but this appeals to us as unnecessary and probably expensive. It has also been suggested that the Army be placed in charge, and the merit of this lies in the fact that the people have entire confidence in the non-political character of the Army and the honesty of its officers. It is also true that to meet a similar scarcity of coal in the Philippines, the Army opened a colliery there and conducted it not only ably, but in such a manner as to demonstrate the value of the coal and of the field, and this led ultimately to the opening of private mines. The Army, however, has other work than mining coal, and no good purpose is served by diverting its officers from their own sphere. Aside from that, the Government has in the Bureau of Mines a corps of men especially well qualified to handle this particular matter. In this Bureau are all the experienced men necessary to man a colliery, from pit boss to general manager. Attracted by the opportunity for travel and study, an unusually capable and well trained lot of engineers has joined the service. A better manager for the proposed enterprise probably could not be found than Mr. George S. Rice, now chief coal-mining engineer for the Bureau. A graduate of Columbia, Mr. Rice has seen extensive service in the coalfields of Colorado, Iowa, and Illinois, having served as engineer, superintendent, general superintendent, and consulting engineer for a number of large companies, including, among others, the Colorado Fuel & Iron Company, Whitebreast Fuel Company, Cardiff Coal Company, and Illinois Collieries. He has opened, equipped, and run a number of collieries as large or larger than any needed in Alaska, and is thoroughly familiar with coal mining, not only in every part of the United States, but in England, Germany, and France. There are other men in the Bureau who have had valuable if not as extensive experience, and they are all men of high character, of just the sort to place in charge of a difficult enterprise. Put the matter in their hands with sufficient capital and adequate authority, and the mine will be well and honestly run. Incidentally, it will furnish the Bureau an excellent opportunity to test each new discovery made in its laboratories, and to try out on a working scale under commercial conditions, its various recommendations for increasing safety and decreasing waste in mining. To the objection that will promptly be made—the high cost of Government work—it may be urged that the facts by no means point conclusively to a necessarily higher cost. The Reclamation Service has repeatedly built on force account at prices below bids from contractors, and the great Los Angeles aqueduct is being built by the City Engineers, and well built, at a cost quite as low as any firm or corporation has ever attained on similar work. On one division the work was done for approximately $2,000,000 less than the lowest bid. Get good men and give them reasonable support and they will build as cheaply for the Government as for a corporation. The common notion to the contrary rests on the excessive cost of jobs let to favored political contractors.

In opening a Government coal mine in Alaska it is important that conditions be made as nearly as possible identical with those under which a private company would have to work; otherwise one of the large purposes of the enterprise, the obtaining of exact information regarding mining costs and other conditions, will be defeated. A definite amount of land should be reserved by the Secretary of the Interior and allotted to the project. Since 2560 acres is the amount permitted one company under the law of 1908, the same acreage might well be set aside for the Government mine. If it is too small for the Government, it is likewise too small for a private company, and if large enough for one, it is certainly sufficient for the other. A definite amount of capital should be allotted to the project, and the coal furnished to the Navy and other departments should be credited to the enterprise at the same rate as if sold to individuals. In figuring costs, depreciation should be fully taken into account, since the plant will need to be renewed from time to time. A sinking fund should also be accumulated and in every particular the enterprise should be run on a business basis.

Since the coal is valueless unless it be brought to the coast, transportation problems must enter largely into any solution of the coal problem. This is true whether the Government or some company mines the coal. To reach the Bering River coalfield, the one most easily accessible, a number of surveys have been made. There are, however, only two routes that need to be considered. The first is a direct line approximately 25 miles long to Controller bay or Katalla. This requires the making of a harbor, and any estimate of expense of shipment by this route must take this into account. Eventually we believe one or more such lines will be built, but for the present the cheapest route would seem to be the longer one to Cordova. This requires a road from the mines almost to Katalla, then north to a junction with the Copper River & Northwestern railroad. The distance is longer, 58 miles, but of the total, 33 miles form part of the main line of the road already built, and the cost of an extra harbor is avoided. This we believe to be the more feasible route for the present. It would have the advantage of permitting through shipment to the copper mines of the interior, while the other would require transfer to boats at Katalla and retransfer to cars at Cordova. A considerable part of the local benefit to be derived from opening the mines would be lost if connection were not made with the Copper River & Northwestern. The tonnage that would be furnished by the Government's own coal requirements would probably be sufficiently attractive to cause one or the other of these roads to be built by private capital. The Secretary of the Interior or the Director of the Bureau of Mines should be authorized to negotiate for transportation to the sea on a basis of an agreed annual tonnage determined by naval requirements, and fixed rates reviewed by the Interstate Commerce Commission. If, on these terms, private capital be not forthcoming for a railway line, the latter could well be built by the Government and operated as a part of the coal-mining enterprise. The cost of the road would be less than that of colliers to bring coal to the Navy from the East, and the cost of operating the whole enterprise, granted that the worst estimates of the excess cost of Government work prove true, would be less than the excess price now paid on the Pacific Coast for Eastern coal. It is taken for granted that arrangements would be made for the Navy and other Government departments to use the Government coal on the Pacific coast. It would probably be necessary to establish supply stations at the tidewater terminals, on Puget Sound, and perhaps elsewhere, and to deliver coal to them either by contract or by using Government colliers. If any coal be sold outside Alaska, and as to the advisability as well as possibility of that there would be much question, the cost of transportation should of course be added to that of mining.

Whatever be the decision as to Government ownership and operation, leasing or any other method of opening the Alaskan fields, existing rights must all be adjudicated as promptly as possible. Under the terms of the Cunningham decision, if they be adhered to, we doubt whether many, if any, of the claims ever go to patent. In any event, final decision can not be expected promptly; and what is needed now is prompt opening of one or more mines. At least one application for patent under terms of the law of 1908 has been made: The Alaska Hard Anthracite Company, for which Mr. F. A. Morrow is the active agent, advertised this summer for patent on 1267 acres in the Bering River coalfield under this law. We know nothing direct of the land or the company, but we sincerely trust that the claims may be well founded and patent promptly granted. It will be remembered that the law of 1908 contains a strong anti-monopoly clause and was enacted on the advice of Mr. J. R. Garfield. As the Cunningham claimants were at one time offered patent under the terms of this law by Mr. Garfield, it may safely be assumed that all possible rights of the people in general are adequately safeguarded in it. If the Morrow claims go to patent, the way would seem to be clear to open at least one private mine which would supplement the Government colliery and permit the latter to be devoted practically to furnishing coal for the Navy and other Government departments. The potential competition of the Government mine would prevent any unreasonable increase in local prices even in the event that actual competition of oil did not operate to do so.

The adoption of the plan outlined would, (1) make the Navy independent as to fuel supply in the Pacific; (2) furnish coal at reasonable cost to local industries needing it; (3) permit the Government to determine the exact facts as to costs and conditions of mining; (4) give the Bureau of Mines an excellent field for testing its theories and recommendations; (5) permit adequate time to be taken to adjudicate existing claims and formulate a really satisfactory policy of handling the coal lands of Alaska.

The Peon and the Kaffir—A Comparison

By T. Lane Carter

I have had an intimate acquaintance with both of them the peon and the kaffir. My association with the black man commenced when I was born, as I was brought up in a part of the South where the negroes outnumbered the whites by twelve to one. I have been employed in parts of Central Africa where there were a handful of white men among thousands of kaffirs. In working with the peons of Spanish America I have often compared them with the kaffirs of Africa. They differ in many ways, and perhaps a paper comparing the two races may be of interest to those not acquainted with both.

The first thought that comes is the importance of these laborers to the mining industry. Without the kaffirs the gold industry of the Transvaal would be impossible on its present huge scale. While the white man has furnished the brains, the black man has furnished the muscle in the development of the gold and diamond wealth of South Africa. In Mexico it is the same way. With all his faults, it is the peon who has done the hard work in the development of the mineral wealth of that country which has been called the 'Treasure House of the World.'

A KAFFIR. A PEON.

One advantage the kaffir has over the peon. The black man has not so much liberty. The main thing that liberty has done for the peon in Mexico is to give him every facility to drink himself to death. One can get intoxicated in Mexico cheaper than in any other country in the world. To my mind, the most serious question there, is not whether the peon shall have full political rights, but how to prevent the excessive use of alcohol. For ten cents gold a man can buy enough of the native liquor to stay drunk for a week. About 40 years ago the beverage which is now the greatest curse of Mexico was introduced. The manufacture of *tequila*, the peon's whisky, commenced in the State of Jalisco, at a town now called Tequila. The industry has now spread to such an extent that peons can buy the liquor everywhere. Not only is the drink highly alcoholic, but it contains an injurious oil. One great authority has asserted that unrestricted use of *tequila* would in time wipe any race from the face of the earth. Unless something is done to reduce the traffic, it is probable that in a couple of centuries the working classes will be killed off by *tequila*, just as the ancient Toltecs of Mexico were silently and mysteriously exterminated by the excessive use of the drink *pulque*, which they discovered. The problem of restricting the use of *tequila* is a difficult one. In the first place, the vested interests controlling the trade are so strong that it would be dangerous for any government to disturb them. To place such a tax on the liquor as to make the cost to the peon excessive, is out of the question. The plant from which this drink is made grows on rocky soil, unfit for any other purpose. Thousands of acres of land formerly useless have been made valuable by its cultivation. The liquor is produced very cheaply. Large sums of money are made by growing *tequila*. When the planter also owns his distillery, he generally makes a fortune. It is curious, though, how often they or their sons become victims of the habit and are killed by drink.

Many thoughtful Mexicans realize the curse of *tequila*. Recently I met a high minded Mexican who refused to buy a *hacienda* where *tequila* was the staple crop, because he did not care to be associated in so nefarious a business. Had he bought the plantation he could have made a fortune, but he preferred earning money in some more honorable way. In some parts of Mexico fully 60% of the people use the liquor freely. Among the poorer classes it is sometimes bought in place of food, on account of its stimulating effect. Grog-shops abound, and women and children have every chance to get the drink. Much of the inefficiency in mining in Mexico is due to drink. Managers dread the *fiestas*, not so much on account of a day or two holiday, but because the men when they return to work are more or less incapacitated by the liquor. Examine the crime record of Mexico and you will find that most of the murders committed in the country are perpetrated by peons while under the influence of *tequila*. The liquor seems to inflame their passions, and a man should be careful how he deals with a drunken peon.

How different is the lot of the kaffir! He never gets any *tequila*, not because he would not love the drink, but because a wise paternal government keeps it away from him. Could he buy *tequila*, I believe the kaffir would drink the peon 'under the table.' This Mexican drink would suit him even better than whisky. But the law prohibits the sale of intoxicating liquors to kaffirs, and hence the black man is prevented from drinking himself to death. The peon can get out and yell, *'Viva libertad!'* and drink as much *tequila* as he wants. But the kaffir knows nothing of liberty and fraternity. He must drink water. Although he enjoys less liberty than the peon, the kaffir has the great advantage of being protected, much against his will, against the ravages of alcoholism. There is no race in the world that is being guarded better than the black men of South Africa. Under this paternalism they are growing strong, and are greatly increasing in numbers.

Another advantage the kaffir has over the peon, and that is that the black man carries practically no burden of taxation, while the peon keeps Mexico going. Save that he cannot get in the middle of the street and yell, 'Hurrah for liberty!' the kaffir has a fine time. He can gather what to him is a competency in one-tenth the time required by the peon, and when he has made his fortune, and bought his wives, the amount he pays to the government is very small. The peon is heavily taxed; the kaffir scarcely at all.

Curiously, the principal food of the kaffir and the peon is the same, namely, corn. It is prepared differently in Mexico than in Africa. In Mexico the ubiquitous *tortillæ* is made by mixing the cornmeal with water and a little salt, and then baking the thin cakes on the hot coals. The black man prepares his 'mealie pap' by mixing the corn with water and boiling the material, making a porridge. The fact that in both Mexico and Africa the natives do most of the work on corn is a proof of the excellence of this cereal as a food. The diet of the peon is more [illegible] than that of the kafir, but corn is his standby. [illegible] among the Mexicans.

At the mines of South Africa the kafirs are better housed than are the peons of Mexico. Where a large body of men is working, as on the Rand, the scheme of a compound as used in Johannesburg and Kimberley [illegible] Central America and Mexico [illegible] the inhabitants [illegible] In the compounds of Africa there is [illegible] for the black man, and it is easy to enforce sanitary regulations, but in Mexico and Central America [illegible] is not so easily understood.

As a laborer the peon excels the kafir in some ways. Mining in Spanish America has been going on for several centuries, and there has grown up a class of workers who are accustomed to underground labor from their childhood. The native methods of mining in Mexico are not suited to modern conditions, but it is not difficult to [illegible] the methods necessary for a company and teach them the difference between 'gophering' and mining. Compared with the number of white men necessary to supervise the kafirs, very few are required in the mines of Mexico. It has been my experience in Spanish America that better work can be obtained by relying on competent Mexican supervisors who are thoroughly acquainted with the ways of the peons than by using a large number of white men. On account of the far higher intelligence of the peons, [illegible] superintendence necessary in working kafirs.

If the kafirs were as intelligent as the peons, the accident death rate would be far lower than it is to-day in the Transvaal. In reviewing the high accident death rate of the Rand, [illegible] of the trouble is due to the low intelligence of the kafir. The mines of Mexico are more dangerous than those of the Rand. There is far more attention paid to the safety of the mines in Johannesburg than in Spanish America. Many mines in Mexico are worked with [illegible] and if kafirs were the workers instead of peons, the death rate from accidents would [illegible] be nearly double.

The peon responds to the [illegible] better than the kafir. When he gets over his first [illegible] and sees the [illegible] of his work [illegible] results. Experience has shown that the only way to work the peon is on contract basis.

In mining the peon has different methods than the kafir. Go through an African mine and you will find the drillers [illegible] If you inspect a mine in Mexico, you will notice that all of the men are working [illegible] one striking and the other holding the drill, and you will find the holes are [illegible] The kafir [illegible] It would be difficult to [illegible] a large number of [illegible] in Mexico. [illegible] the conditions.

There is not a great deal of difference between the cost of labor to the mining companies of South Africa and Mexico. [illegible] I recently found that the wages paid to the natives working [illegible] In South Africa the [illegible] South Africa the mining companies [illegible]

In Mexico it is impossible to [illegible] in South Africa. [illegible] in Spanish America. [illegible] there would [illegible] be [illegible] against such [illegible]

And yet the indentured kafir of South Africa is better off than the free peon of Mexico. At the end of his service the black man has saved enough money to buy one or two wives, and becomes a gentleman of leisure for life. You do not find many peons that have any money.

There is this difference between the two races. The peon spends his money freely, the kafir hoards his savings. I have seen hundreds of kafirs at mines in Africa pass by the store and never go in to buy a single article. It would, of course, be an easy matter to induce the black man to loosen up on his money. Just introduce tequila among them, and they would break up all their savings.

The tastes of the peon are far more elevated and refined than those of the black man. When he gets money he frequently buys pictures of saints or statues. He is passionately fond of music, and one can not travel far in Mexico without seeing a guitar. The kafir in his kraal does not believe much in clothes. The height of the peon's ambition is to buy an enormous sombrero gaily decorated with silver and gold braid, so that he can appear as a gentleman on Sundays. In out of the way mines in Mexico it is no uncommon thing for the peon to spend all his money at the company's store.

The kafir is the most docile being in the world. He will stand more abuse from his white boss than any other laborer in the world. I have seen miners in South Africa kick and strike kafirs with no retaliation on the part of the black man. Had these white men treated the peons in the same way, the chances are the Mexicans would have killed them later on. One of the first things to learn in dealing with the peon is that it is not safe to hit him, as it is a kafir. If his offense is not great, all the boss has to do is to quietly inform him that his services are no longer required. For some bad breach, such as theft or fraud, the peon should be arrested. The peon is far more averse to a jail sentence than is a kafir.

To get the maximum amount of work out of either class of labor is an art. Experience is the great teacher, but there are several points that might be mentioned. In the first place, it is necessary to know how to talk to the laborers. As scarcely any of them can talk English, it is essential to learn the black man's lingo, and in Mexico to talk to the peons in Spanish. Even if you are not directly over the men but are a 'big boss' it is an advantage to know the language, for it increases their respect for you. To the raw kafir or peon it is almost incomprehensible that a man cannot understand their talk. I have seen Mexicans [illegible] at foreigners [illegible] even after they were informed that the visitor did not understand a word of Spanish. In South Africa they have evolved an extraordinary jargon called 'kitchen kafir,' which is the means of communication between the two races. The majority of black men, especially the [illegible], this dialect is [illegible] Thousands [illegible] of distant tribes come to the Rand to work with a language of their own, and for a time 'kitchen kafir' is unintelligible to them. The languages of the various tribes are as different as [illegible] I have often seen a white man familiar with [illegible] languages act as interpreter between a Zulu and a [illegible] Now and then one finds a Hollander in charge of a compound who by years of contact with the tribes has learned [illegible] of the native languages, but as a rule the [illegible] 'kitchen kafir.' In Mexico one can [illegible] Spanish from a book, but in Africa one must pick up the jargon by word of mouth. Three or four hundred words are about all that are required. One could not very well hold a philosophical discussion with the black man by means of 'kitchen kafir,' as grammar is lacking, but the lingo answers the purpose as well as 'pigeon English' does with the Chinese.

The peon is a better miner than the kafir, and has a [illegible] to break ground. Physically he is not as strong as the black man, but he has great powers of endurance. [illegible] the peon would be a better miner than the kafir. As it is, there is not much choice between the two.

There is one point in common which every one who has employed the two classes of labor has noticed, namely, the tendency to waste labor because it is cheap. I have often seen a white mechanic in South Africa look for a kaffir to carry his coat and tools, when he left the shop to work on the outside. In Mexico it is even worse. The tendency is to have two men at work where in other countries with high-priced labor, one would be sufficient. In the homes at the mines in Mexico you will find double the number of servants that you see elsewhere. Where labor is cheap it is generally inefficient, and this is probably the reason that mines with these two classes of 'cheap' labor cannot, as a rule, show lower working costs than where high-priced, highly efficient help is employed. In Mexico the wages paid the peons have doubled in the last twenty years. The tendency is for the wages to go still higher. No doubt this marked increase in pay is due to the advent of the foreigner. It is a well known fact that the peon will frequently work for a Mexican master for less wages than he earns from a European. There is a considerable difference in the wages paid the peons in northern Mexico, where the influence of the high pay of the United States is felt, and the amount earned by the workmen in southern Mexico, where the foreigner is not so conspicuous. In Africa it is customary to pay the kaffirs at the end of thirty shifts worked. This system does not suit at all in Mexico, where the peons like to be paid every week. It is the usual custom to pay them every Saturday or Sunday in Mexico.

KAFFIRS OPENING THE PREMIER DIAMOND MINE.

The kaffir is generally considered a heathen, and the peon a Christian, but when it comes to superstititon the Mexican is far more affected by signs and wonders than is his phlegmatic brother of Africa. Around every old mine in Spanish America there has grown up a number of legends and myths; spirits and goblins often are seen or heard underground, while the devil himself is warded off by the frequent use of crosses and candles. Possibly the kaffir is not far enough advanced mentally to have the vivid superstition of the peon.

The man who is responsible for the handling of these laborers should study most carefully their idiosyncrasies. By knowing how, he can frequently increase the efficiency of the workmen from 15 to 20%. He has need of much patience and observation to obtain the best results. The mining industry owes a great deal to the peon and the kaffir, and any time given to their advancement and betterment is that much gain to the industrial world.

— —

A NEW SHAFT-SINKING RECORD is reported in *Mines and Quarry*. During the thirty days between April 21 and May 21, the Live Oak Development Co., at Globe, Arizona, sunk its No. 2 shaft vertically 205½ ft., the miners doing their own timbering in addition. This is a double-compartment shaft, 4½ by 5 ft. in size. Three shifts, of four men each worked. All drilling was done with two U S 2¼-in. Sullivan rock drills, driven by air furnished by a class WB straight line two-stage Sullivan air compressor, with 16 by 16-in. steam cylinders, and 18 and 11 by 16-in. air cylinders. Shafts have been sunk farther than this in South Africa in thirty days time, notably that of the Van Ryn Deep in July and August 1910, 279 ft. This shaft was 7½ by 20 ft. in size, but was comparatively flat, being driven at an angle of only 22° from the horizontal. This work was done with six 3¼ in. drills. From May 1 to May 31, the Live Oak shaft was driven 183 feet.

Concrete for Oil Reservoirs

*Considerable experience has now been had in the Southwest in the use of concrete for oil reservoirs and other purposes where the asphaltic oils of that section of the country remain more or less continuously in contact with concrete. The railroad companies are large users of oil, and among these the Santa Fé is a leader in such practice.

On the Albuquerque division, the division engineer, E. E. Ball, reports that concrete-lined reservoirs have not been affected by oil. Some slight effect had been noticed on the concrete floors and foundations of boiler-shops and pump-houses, where the dripping of oil on the concrete apparently caused it to disintegrate somewhat. This might be due, it was said, to the action of the oil, or it might be due to the fact that the concrete was placed during cold weather and was frosted during setting.

On the San Joaquin valley division, William L. Bradley directs attention to experience with a reservoir at Rheem, near San Pablo, belonging to the Standard Oil Co., which was burned in the early part of 1910. This reservoir had a concrete lining on the sides and bottom. The lining was laid off in slabs about 3 ft. wide, with a joint extending from the surface several inches into its body. These joints were intended to offset the cracking by shrinkage and apparently answered the purpose well. During the fire the oil burned down so that when it was extinguished and the basin was visited by Mr. Bradley, there was only about 2 or 3 ft. depth of oil and water in it. This left practically all of the sides exposed, and an examination of them showed that possibly some of the joints had been opened wider than otherwise by the action of the fire, but there were only a very few small irregular shrinkage cracks elsewhere than in the joints, the concrete being in excellent condition. Although Mr. Bradley reported that the concrete lining was in good condition, it is understood that the Standard Oil Co. has discontinued the use of concrete for lining its reservoirs in that part of the country for the reason that it believes the oil gradually enters the concrete and disintegrates it, and that this is particularly noticeable in the case of reservoirs or basins holding distillate, which apparently injures the concrete far more rapidly than oil. So far as the experience of the valley division itself is concerned, several concrete linings have been used for oil reservoirs and sumps, and no special effect of the oil has been observed.

A number of tests have been made on the Arizona division of the railroad under the direction of W. H. Oliver. Concrete-lined oil sumps are there used and the penetration of the oil into the concrete has been practically *nil*, no noticeable detrimental effect of the oil having been discovered. At one place the depth of penetration of the oil into the concrete was only about the thickness of a sheet of ordinary letter paper.

At the pumping stations of the Arizona division, concrete service-storage reservoirs for fuel oil have been used. Although the oil is at a comparatively high temperature on this division, the concrete in the sumps has not shown any sign of deterioration. While the quantity stored in any sump is small, the penetration of the liquid into the concrete would be just as rapid as in a much larger basin, in all probability.

---

*From *Engineering Record*.

The Paying Copper Mines of Michigan

By J. R. Finlay

[*]Only nine copper companies in Michigan have made money during the past five years. Their actual earnings were $50,937,690 with copper averaging 15.3c. per pound. Had the metal averaged 14c. the earnings would have been $41,200,000. This would be $8,240,000 per year.

If it could be assumed that these mines would last forever the investor would probably be satisfied with 5% income and he would probably capitalize the average earnings of $8,240,000 into a present value for the group of $164,800,000. The fact is that these mines are not worth even half of this amount, because their future life is not by any means perpetual. On the contrary, their future is much less promising than is popularly supposed. These mines have shown unusual persistence in depth, but the limit of profitable working is now in most cases in plain sight. It must not be forgotten that the tonnage maintained now is three time as great as the mines have averaged in their fifty years of life. It will be observed that the Tamarack mine is not in the list of profitable companies. This mine has become worthless because the Calumet conglomerate, by far the richest deposit in the whole district, has failed in depth. The Tamarack owns an irregular tract immediately below the Calumet & Hecla mine and including the whole downward extension of the great lode which has enabled that property to pay $115,000,000 in dividends. In the upper portion of its mine the Tamarack was able to earn handsome profits and it paid up to 1906 a total of $9,420,000 in dividends. Since then it has uniformly lost money because the rock no longer yields enough copper to meet expenses. The depth at which the lode became unprofitable was approximately 8000 ft. on the slope. If this richest of all deposits has played out in this manner it may be taken as a sure inference that inferior lodes will play out at lesser depths.

Valuations of the Copper Mines

Mohawk	$3,500,000
Ahmeek	7,200,000
Allouez	1,500,000
Wolverine	3,700,000
Osceola Consolidated	6,000,000
Calumet & Hecla	31,400,000
Quincy	3,250,000
Isle Royale	1,450,000
Superior	1,000,000
Baltic	5,000,000
Tri-Mountain	165,000
Champion	5,000,000
Lake	300,000
Atlantic	350,000
Total	$69,815,000

Kearsarge Lode.—Beginning at the northeast end of the district we have first the Kearsarge amygdaloid, on which are situated the Mohawk, Ahmeek, Osceola Consolidated, Allouez, Wolverine, and Centennial mines. This is the longest lode in this district. It dips northwestward at an angle of about 37°. Its thickness is some twelve feet. Its length is five miles. While this vein is mineralized quite uniformly for the above length there are two areas or oreshoots that are distinctly richer than the average. These occur on the Wolverine and Ahmeek properties. These two enrichments appear to be substantially of the same size and character, but apparently the Wolverine orebody is the richer.

The Wolverine has been able to maintain a yield of about 27 lb. of copper per ton, but there has been some decline. At first the rock yielded 30 lb., but it has now gone down to about 25 lb. per ton. The conditions for cheap mining are ideal and the Wolverine has been able to produce the cheapest copper of the district, its cost per pound being less than 8c. The Ahmeek mine is much younger and is just arriving at its most profitable stage. It has been securing about 22 lb. refined copper per ton and has brought its tonnage up to about 550,000 per year. I calculate that this mine will have to spend considerable money for further construction and development in order to bring its output up to 800,000 tons per year. Including the probable expenditures for construction, I estimate that the mine can produce copper at slightly over 9c. per pound for the next ten years.

The other mines on this lode are not so good, although the South Kearsarge branch of the Osceola Con. seems to have a portion of the Wolverine ore-shoot. We may calculate with certainty that part of the Kearsarge lode will prove profitable down to a depth of at least 6000 ft. It is not an unfair supposition that at least 60% of its area would be mined to that depth and will produce 16 lb. per ton. William Hague has estimated that at a depth of 2000 ft. on the slope the lode is yielding an average of 18 lb. per ton, but that the yield may be expected to diminish with greater depth. It is probable that the lode will be able to produce to a depth of 6000 ft. some ninety million tons of ore, of which some twenty million tons have already been mined. This would leave seventy million tons to be taken out.

The Mohawk mine has a surface area covering the Kearsarge lode of about 480 acres, this being the upper portion from the outcrop down to the Ahmeek line, which will be reached at an average depth of 2500 ft. along the slope. About 70% of the territory so far explored appears to be mineable and yields about 55,000 tons of ore or approximately 800,000 lb. of copper per acre. On this basis approximately 330 acres containing 264,000,000 lb. of available copper was the full measure of production possible in this territory before mining began. About 88,000,000 lb. has been already removed, leaving for the future a product of about 176,000,000 lb. This can be mined in approximately 15 years at a cost of 11c. per pound and a profit of 3c. per pound, giving a total profit of $5,280,000 and a present value of $3,500,000.

The Wolverine mine has a surface area covering the lode of about 215 acres. The total production to date has been approximately 107,000,000 lb. and the future production will be 80,000,000 lb. This can be mined in 9 years at 8c. per pound, leaving a profit of 6c. per pound and a total profit of $4,800,000, and a present value of $3,700,000.

The fairest method of measuring the probabilities of the Ahmeek mine is to compare it with the Wolverine and Mohawk combined. The reason for this is that the Ahmeek contains, as mentioned above, a rich portion of the vein comparable to that of the Wolverine, but not so rich. It contains only 22 lb. of copper per ton, against 27 lb. for the Wolverine. A large part of its territory is simply a downward extension of the lode from the Mohawk property. The total area of the Ahmeek property covering the Kearsarge lode above a depth of 6000 ft. on the slope is 660 acres, against a combined acreage of 695 acres for the Mohawk and Wolverine. I do not believe that the Ahmeek property is likely to produce more than 75% as much copper as the two properties combined. The portion underlying the Mohawk has the pronounced disadvantage of containing only the deep levels. I therefore base my valuation of the Ahmeek mine on the assumption that it will produce three-quarters as much copper as the Mohawk and Wolverine combined. This will give about 335,000,000 lb., of which 45,000,000 has been mined, leaving 290,000,000 lb. to be extracted. It is a fair assumption that of this, 150,000,000 lb. will be produced during the next ten years at an average cost of a trifle over 9c. per pound, making a total expected profit in that period of about $7,500,000 and a present value for that period of about $5,500,000. The remainder, 140,000,000 lb., will probably be low grade, costing 11c. per pound and making a profit of $4,200,000 for a period of 12 years following the first 10. The present value of such an expectation is about $1,700,000, so that the maximum valuation of the Allouez is $7,200,000.

---

[*] Abstract from a report to the Board of State Tax Commissioners of Michigan.

The Osceola Consolidated owns the North and South Kearsarge mines. The South Kearsarge is rich like the Wolverine, but it is largely worked out. The North Kearsarge is poor like the Mohawk. Without going into details, the total expectation is about 21,000,000 tons containing about 300,000,000 lb. copper. This can be mined in 15 years at a profit of 3c. per pound, totaling $9,000,000. This would give it a present valuation of approximately $6,000,000.

The only remaining mine on the Kearsarge lode that can be classed as profitable, the Allouez, may be counted on for about 10,000,000 tons and 140,000,000 lb. of copper. The operating record to date of this mine is not very flattering, costs for the past five years being 15c.; but in 1910 the cost was reduced to 11.6c. This mine has only two shafts, which gives it a maximum producing capacity of 400,000 tons per year. At this rate it will take 25 years to exhaust the property, and it is not safe to count on the cost of copper at less than 12c. per pound. This gives, then, a total of $2,800,000 profit to be expected in the 25 years. This gives the mine a present value of only $1,500,000.

Osceola Amygdaloid Lode.—Only one mine is working on this lode at present, the Calumet & Hecla. On this property it has been developed for a length of 9900 ft., but a considerable portion at the North End is not apparently profitable. Since December 1900, this lode has produced 3,301,766 tons. The abandoned extension on the Old Osceola mine toward the south is supposed to have produced 4,000,000 tons. The yield of copper on Calumet & Hecla ground alone has been about 55,000,000 lb. This vein is not as uniform as the Kearsarge. Mr. Hague summarizes the situation as follows. "From the fact that the Osceola lode in the Tamarack workings shows a yield of about 13 lb. per ton at a depth of 6100 ft. on the dip of the lode, and from the fact that the Osceola branch of the Osceola cone has been closed, the lowest workings being 4700 on the dip of the vein—an arbitrary limit of 5000 ft. has been placed upon profitable mining on the Osceola lode—providing the price of copper remains the same, and provided that no material reduction in working costs takes place while operating at such depth." On this basis, and assuming that 60% of the lode will prove mineable, it is estimated that it will yield some 23,000,000 tons, which will produce 330,000,000 lb. of copper. This will be produced in 20 years at a cost of 11c. per pound, giving the mine a present value of $5,900,000.

The Calumet Lode.—This is the single conglomerate vein worked in the district. It is by far the richest in the whole region and has paid nearly 70% of all the dividends of the Michigan copper mines. It has been worked by the Calumet & Hecla and Tamarack companies. The Tamarack, as mentioned above, has become unprofitable on account of great depth and the Calumet & Hecla has its possible future sharply defined. This fact is ominous for the prosperity of the district as a whole, for the failure of this great deposit is not being compensated for by new discoveries. The Tamarack mine has no payable ore at all in sight, and I appraise its value at zero.

The Calumet & Hecla has on its conglomerate lode about 27,000,000 tons of ore reasonably assured at an average estimated content of 26 lb. per ton, making a total of 702,000,000 lb. The tonnage is divided roughly between 5,000,000 tons of shaft pillars, estimated to contain 50 lb. per ton and 22,000,000 tons of other rock in the lower portions of the mine estimated to contain only a shade over 20 lb. per ton. These figures contrast sharply with the former richness of this deposit, for ten years ago the average yield of the Calumet & Hecla rock was 60 lb. per ton. Great progress has been made in reducing costs. The mine was excellently equipped with magnificent machinery during the bonanza days, and this machinery has proved ample for the ultimate requirements of the property. The development required to extract the ore has been largely completed. As a consequence, I believe the mine can be worked at a great profit until it is exhausted. I estimate for the remaining copper a cost of only 9c. per pound, which will leave a profit of 5c. This will give the property a profit of $35,000,000 in 20 years on this lode, giving it a present value of $21,000,000. The company also claims, and I have no reason to doubt, that it can produce 150,000,000 lb. of copper from some 30,000,000 tons of conglomerate sand now piled in Torch lake. This can be produced at about 9c. per pound during the next 20 years, the present value being not less than $4,500,000. The total value to be credited to the conglomerate lode, therefore, at the present time is about $25,500,000. For the whole property the valuation is $31,400,000.

Pewabic Lode.—This is an amygdaloid at present worked only by the Quincy mine. It is not a single vein, but a series of amygdaloid flows carrying copper for a thickness of about 200 ft. The main lode, which contains most of the workings, is near the centre of this series, but perhaps nearer the foot-wall side. The production of the Quincy mine up to the end of 1910 was 458,000,000 lb. of copper. This is exclusive of the production of the old Franklin mine, whose property is now embraced by the Quincy. I have not been able to verify the production of the Franklin, but it was apparently some 150,000,000 lb. The total output of the lode to date may be estimated at about 600,000,000 lb. The vital point in the present situation is that the property has been exhausted to a great depth, approximately 5200 ft. along the slope. It has long been recognized to be in a dangerous condition on account of possible caving. A few years ago the Atlantic mine suddenly closed and was permanently abandoned by the operating company. The yield of copper per ton for the last 5,000,000 tons mined has been less than one-half the yield of the first 5,000,000. The mine is well equipped and undoubtedly secures the best results obtainable under the conditions, but it is facing the three adverse factors of great depth, a declining yield, and the danger of caving. The total production possible from the lode to a depth of 7000 ft., which may be taken as the ultimate profitable depth, will not exceed 200,000,000 lb. A fair present value is based on 150,000,000 lb. to be produced in 7 years at a cost of 11.3c. per pound (which is the average of the past five years) and a profit of 2.7c. per pound. The total profit expected in 7 years is $4,050,000, giving it a present value of $3,250,000.

The Hancock Con. M. Co. is projecting some explorations on the Pewabic lode, but has not yet reached it. This property is nothing but a prospect and I shall not consider it worth anything. The Franklin mine is also exploring for the Pewabic lode, but so far as present appearances go the Quincy owns all the ground which is likely to be profitable.

Isle Royale Lode.—The above described deposits are all northeast of Portage lake. The only two lodes being worked southwest of Portage lake with any pretensions to success are the Isle Royale and Baltic. The Isle Royale was discovered in the early days and has been worked with success for 50 years. Its record for the past five years shows a cost of 16.7c. per pound for 21,902,000 lb. of copper. On this record it might be put down as unprofitable, but there is another side to it. The output has been brought up from 192,000 tons in 1906 to 521,000 tons in 1910. The yield of copper per ton has remained substantially the same and shows an average for five years of 14.6 per ton. The cost in 1910 was only 11.8c. per pound, which seems warranted by the yield of the rock. This indicates that the mine has some value. It seems reasonable to expect that it will produce 112,000,000 lb. above the 4000-ft. level in 16 years at a cost of 12c. per pound. This indicates a total profit of $2,240,000 and a present value of $1,450,000.

Baltic Lode.—This is the last important vein discovered in the country. It was opened up about 1897, although some former unsuccessful work has been done upon it.

Four mines are situated upon this lode, the Superior, Baltic, Tri-Mountain, and Champion.

Mr. Hague comments upon the Superior as follows: "This property is in the prospective stage, though a very promising one. One shaft has been put down about 15 levels. A total of 286,566 tons of ore yielding 5,602,408 lb. of copper has been hoisted from drifts, as practically no stoping has been done. This is about 19½ lb copper per ton. Depth and lateral extent must be obtained before any definite statement can be made as to life or yield. About 1400 ft. laterally on the vein has been opened to date. If the Baltic may be used as a standard for this property the following figures may be used for the tonnage developed: 1,900,000 tons at 19½ lb. equals 37,000,000 lb. of copper." One unfavorable feature about this property is that the outcrop of profitable ore is short. On the theory that the depth of an ore-shoot has some relation to its length, there is some reason to fear that the mine may not prove extensive. It is therefore hazardous to count upon indefinite extension downward. It seems fair that the probable value of the property should be based on an expected output of 75,000,000 lb., this being twice the amount now opened. Since the property is not equipped, it is probable that 2c. per lb., or a total of $1,500,000, will be needed. Therefore the total expected cost may be put at 12c. per pound, leaving an average profit of 2c. per pound, or $1,500,000 to be obtained in 15 years. This would give the property a present value of about $1,000,000.

The Copper Range Consolidated Co. owns the Baltic, Tri-Mountain, and Champion mines. Each of these works upon a separate ore-shoot and together they cover a length of more than three miles along the vein. Taking the three orebodies in the aggregate, the length is such that one would be disposed to concede the probability of the ore extending to a great depth. However, the ore-shoots are separated by big stretches of entirely barren ground. The ore-shoot of the Tri-Mountain, which is the central one, weakened abruptly at a depth of about 700 ft., and the mine has become practically unprofitable. The management, however, is not disposed to take these unfavorable developments seriously, but fully expects to find better ore at greater depth in all three mines. Under these circumstances I do not feel disposed to express an opinion as to the future of these properties, except that the continuity is not so well demonstrated as in the case of mines north of Portage lake. There are undoubtedly large gaps of barren territory in the vein separating the richer bodies both laterally and vertically. It is to be remembered that these mines are well managed and have been very profitable, so that a considerable falling off in yield can be withstood before the profits will be extinguished.

At the Baltic mine Mr. Hague estimates ore reserves at 3,400,000 tons reasonably assured at 22 lb. per ton, making 75,000,000 lb. copper. If we assume that this is reasonably certain to be extended to 5,000,000 tons and 110,000,000 lb. of copper, we get an assured life of about 7 years. The cost of production is less than 9c. per pound, profits 5c. This gives an expected profit in seven years of $5,500,000. It is perhaps reasonable to expect that further discoveries will enable the company to make additional profits, which will be sufficient to pay interest on a full valuation of this property after the seven years have expired. It seems, therefore, fair to give the mine a full valuation of $5,000,000.

The Tri-Mountain mine has been able to maintain a cost per pound of copper at about 12.8c. for the past five years, but with a diminishing output both of tonnage and copper. The future of the mine is entirely prospective except for about 16,000,000 lb. of copper which may be obtained in the next four years at a profit of $192,000. The present value is $165,000.

Mr. Hague's estimate of ore reasonably assured at the Champion mine is 5,000,000 tons, which will produce 110,000,000 lb. of copper. The same assumption can be made for the Baltic as regards cost and the valuation can be placed at the same figures, $5,000,000.

Lake Mine.—Another property situated some twenty miles southwest of the Copper Range group is generally supposed to be valuable. This is the Lake property. It is not by any means assured that this mine will ever pay a dividend. So far 14,485 tons of rock has been shipped from this mine and stamped, with a yield of 318,050 lb. of copper, this being an average of 21.95 lb. per ton. If a large tonnage of ore of this grade could be secured and mined at average cost, the property would unquestionably be valuable. But it is stated by the management that the ore shipped to the mills was selected and cannot be taken as a fair average of the mine. At present all effort is being directed toward equipping and opening the mine on a sufficient scale to place mining on an economical basis. Ore will then be sent to one of the Copper Range mills. The cost of freight will be from 15 to 20c. per ton. It is not probable that under these circumstances operating costs will be less than $2.10 per ton. This will make 15 lb. per ton the smallest yield, that can possibly meet expenses. It is hoped that this mine will prove to be something like the Baltic, in which case about 2,000,000 tons may be conceded to be opened, which might yield 40,000,000 lb. of copper. Conceding that this product may be obtained at a profit of 1c. per pound during the next ten years, we get a present value of about $300,000 for this property.

Eastern Metal Production

The total value of the mine output of gold, silver, copper, lead, and zinc in the Eastern or Appalachian States for the year 1910, according to H. D. McCaskey of the U. S. Geological Survey, was $10,127,304, against $11,818,531 in 1909. This represents the production of 100 mines, of which 61 were gold placer mines, many of them small. The total gold output from all mines was 8,974.63 fine ounces, valued at $185,522, an increase over 1909 of $29,582, and the silver production, recovered entirely in the refining of gold and copper produced, was 91,595 fine ounces, valued at $49,461, an increase over 1909 of $14,667. Of the gold output in 1910 the placers yielded 1524.54 fine ounces or 17%, the quartz ores 6977.57 fine ounces or 78%, and the copper ores 472.52 fine ounces or 5%. This 5% was derived from 774,040 short tons of copper ore mined, with an average gold and silver value of $0.076 per ton, against 787,146 tons in 1909, with a gold and silver value of $0.06 per ton. There were 60,410 short tons of dry and siliceous ores mined in 1910, with an average gold and silver value of $2.39, against 25,531 tons in 1909, with a value of $4.33.

The copper production, from copper and iron ores, was 17,923,412 lb. valued at $2,276,273, a decrease of 2,430,813 lb. in quantity and of $369,766 in value as compared with the 1909 figures. Most of the copper produced in these States comes from the Ducktown district of Tennessee, which contributed 94% of the output in both 1909 and 1910. The copper ores yielded an average of 23.2 lb. of copper to the ton of ore in 1910, against 25.9 lb. in 1909.

The production of lead, all from lead-zinc ore, was 198,850 lb., valued at $8750, in 1910. No mine production of lead was reported for 1909.

The zinc output in 1910 was 140,875,886 lb., figured as spelter, valued at $7,607,298, a decrease from the production in 1909 of 25,452,973 lb. and of $1,374,460. The output of zinc ore was 411,381 short tons in 1910, with an average recoverable content of 342.4 lb. of zinc per ton. Of the zinc output of the Eastern States in 1910, over 97% came from New Jersey, the remainder being produced in the lead-zinc belt of Virginia and Tennessee.

THE engraving division of the U. S. Geological Survey printed during the fiscal year ended June 30, 1911, 7,283,894 geologic, topographic, and other maps, many of them in several colors, each requiring a separate impression. Some of the geologic maps require as many as twenty printings. The total number of printings during the year's work was probably not less than 45,000,000 or 50,000,000.

Estimating and Valuing the Future of Mines

By Morton Webber

Among those professionally interested in mining and more particularly those who have specialized in valuation, there exists considerable divergence of opinion as to method in arriving at an equitable valuation of the future possibilities of a developed mine. Blocked out ore can be measured and its net value computed as tangible assets, but the appraisal of the possibilities of vertical and lateral ore extensions can only be computed by inference and, therefore, an appraisal must be a matter of experience and judgment. The factors that should be balanced are many and vital, and inasmuch as some are at variance with others, fair valuation is one of the most difficult duties of the engineer.

Too frequently is it the case that this particular phase in an examination is shirked under the cloak of conservatism. Conservatism, in its true sense, is essential in every report, as the valuating engineer should primarily endeavor to prevent the loss of a client's money. This should be basic, but conservatism should not permit the engineer to evade an issue and discount obvious possibilities, merely to keep himself right. Most capitalists know of innumerable cases where through the timidity of their engineer they have lost excellent chances of investing in properties that have subsequently proved profitable. However, the cursory reader must not interpret these observations as an indication of undue optimism. A report is either correct or incorrect in presenting facts and possibilities as they are, and it is no more the earmark of a competent mine valuer to minimize possibilities than to magnify them.

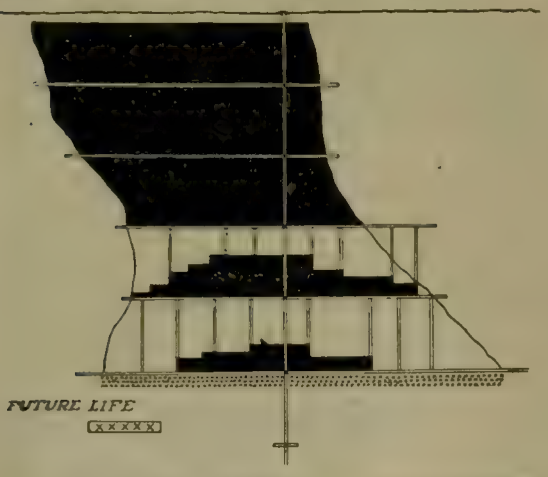

Fig. 1. MINE (A) WITH 65,000 TONS, NET VALUE $130,000.

A mine value is based on three main factors: (1) positive net ore; (2) probable net ore; (3) probable extensions of orebodies. The inferential main factors that determine the value of the future extensions are five in number: (1) the character of the deposit in respect to past geological experience in similar deposits; (2) the size of the deposit in respect to length and width; (3) the question of secondary alteration; (4) the depth to which the mine has been gutted; (5) the experience in the immediate neighborhood of the persistence and continuity of orebodies at depth. Few mines can be bought on the basis of ore reserves alone. Good mines that are for sale are becoming scarcer every year, and on this account the mine valuer is, by the laws of supply and demand, forced more and more to assign a definite purchase value to future possibilities.

A proportionate basis was inaugurated some years ago according to which the net value of the ore reserves of a mine are taken to represent a percentage of the total valuation, the balance being assigned to future possibilities. The relative proportions, one to another, are determined for each mine, depending upon the manner in which the orebodies are found to go down, possibility of lateral extensions, and the possible intersection with other orebodies. In other words, if a figurative example be taken of a mine having $700,000 net in sight, together with a mill capable of yielding $100,000 net per annum, a fair price would be $1,000,000, provided the bottom of the mine was sound. In other words, superficially, the future possibilities are appraised at 30% of the total purchase price, or $300,000. These figures serve only for illustration, as they are decidedly inaccurate inasmuch as the future possibilities in this case are really appraised at $461,200, because the present value of $700,000 locked up in ore reserves drawing no interest is only $538,800 because of the distribution requiring seven years, at the rate of $100,000 per annum. In the risks of mining, when dealing with ore reserves, an investor is entitled to figure what his locked-up money would be worth at a similar risk, and 7% is the least that should be expected.

This method is still popular with many who operate and deal in mines, and is still practised by many well known engineers. However, if it be analyzed it will be found to have little to recommend it, either in the interest of buyer or seller. The magnitude of ore reserves in any particular mine is a matter of administrative policy. A small mill in combination with an energetic policy of development will result in the mine maintaining a large ore reserve. A large mill on the same mine accompanied by an ordinary development policy will result in an ore reserve, proportionately reduced. It is, therefore, obvious that the same mine may be developed to the same depth under two administrative policies as indicated and exhibit the same earmarks of permanence, yet, under this proportionate method of valuation, the appraisal of the future possibilities results in entirely different valuations of the same mine bottom. Such a process has therefore nothing in keeping with common sense.

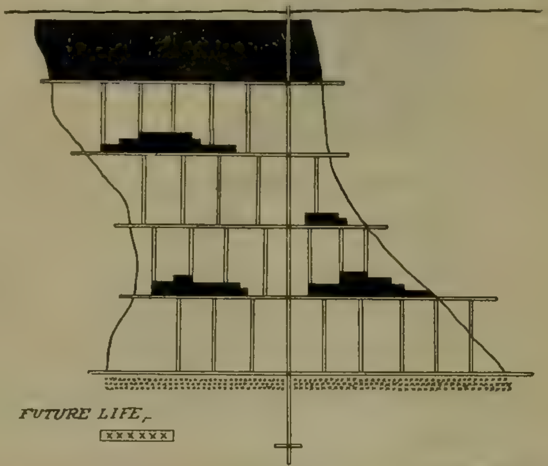

Fig. 2. MINE (B) WITH 125,000 TONS, NET VALUE $250,000.

Fig. 1 and Fig. 2 further illustrate the weakness of the proportionate method and will, moreover, probably convince the reader that there is little interdependence between existing ore reserves and future possibilities. The diagrams are supposed to represent the same mine worked and developed down to the same horizon under two different administrative policies, and there is the same length and thickness of oreshoot exhibited in both cases in the bottom of the mine. Fig. 1 shows the mine as the result of a proportionately large mill having exhausted the orebodies down to the third level. The ore remaining is estimated at 65,000 tons or about one year's ore supply for an imaginary 200-ton mill.

Figuring on $2 per ton profit in both illustrations, the profit in sight is $130,000, less interest. Fig. 2. represents the same mine where supposed to have only a mill of about half the capacity, and the profit in sight is 125,000 tons or $250,000, less interest. Allowing for the lateral extensions of the ore-shoot with depth it is probable that if the proportionate method was used by the valuer that he would be willing, in both cases, to allow 30% of the total price to be represented by future possibilities, and that 70% would be backed up by net profit in sight. This, then, gives total valuations of $185,714 and $357,142. Deducting the profit in sight in each case, $130,000 and $250,000, leaves the relative valuations of the identical mine bottom as A, $55,714, and B, $107,142. The crossed portion indicates the future possibilities. These are the same in both cases, yet, although the same method is applied on the same mine bottom, the disparity is enormous.

The foregoing calculation is sufficient for illustration, but the discrepancy is materially greater when the refinement of actual conditions is introduced. In cases A and B the ore reserves must be regarded as locked-up money drawing no interest, and, as previously explained, the purchaser is entitled to compare this with what his money could be earning at 7%. Otherwise it would be poor business to buy ore reserves. In the first case the 200-ton mill would absorb the ore reserves in about one year, and in the second case with a mill of half the capacity the ore reserves would supply the mill at least four years. In the first case the value of 65,000 tons is $130,000 net. The value of this sum less one year's discount interest at 7% is $121,420. The second case is a little more involved, inasmuch as the ore reserve is consumed at the rate of 31,250 tons per annum for four years. The $250,000 is therefore received at the rate of $62,500 per annum. Calculating interest on the four payments until they are received at 7%, the present value of the $250,000 ore reserve is found to diminish to $211,614. To reiterate, the discount value on the first payment of $62,500 is $58,375 and the second $54,552, and so on. To arrive accurately at the respective valuations of the future possibilities, the two cases summarize as follows: Case A, total price as before, $185,714, deduct $121,420, the discount value of the ore reserves as shown, and the valuation of the future possibilities is then $64,294; case B, total price as before, $357,142, deduct true discount value of ore reserve computed at $211,614 as shown, leaving value of future possibilities at $145,528, as against $64,294 for case A.

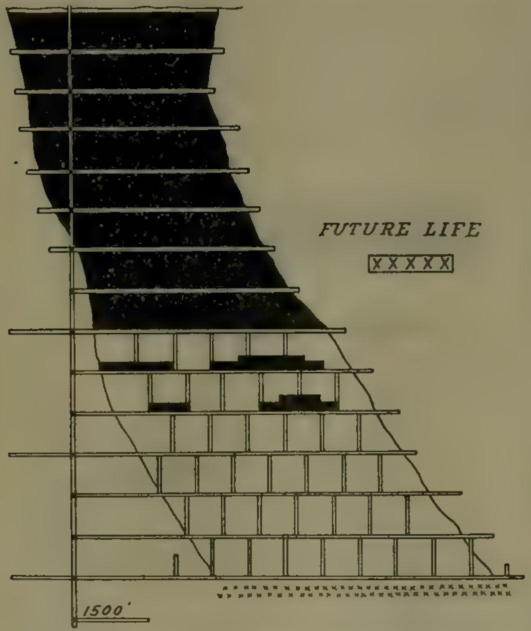

FIG. 3. MINE (C) WITH NET VALUE $950,000.

The proportionate method is decidedly attractive superficially. It might be said that it is seductive. A process that apparently possesses as a fundamental the idea of securing 70% of a purchaser's money by net profit in ore reserves might well be expected to be popular with capital interests who deal in mines. Nevertheless, it is woefully misleading. A large and important ore reserve, instead of being an item of security might become the means of a purchaser making a very bad investment in respect to future expectations. The previous examples which have been reduced to the fine point of actual conditions attest this. If the two cases instead of being the same mine only worked under two different administrations, be imagined to be two distinct mines having the same relative disparity of ore reserves, but in other respects exactly similar, the fallibility of the system is again cogent. Allowing for the basic discount interest, the future of A has been computed at $64,294 and that of B at $145,528. As the bottoms of the mines at the same period are identical, there is no reason to expect better results from B than A. Mine B might show decrease either in grade or value in two or more levels. Mine A might go down for an additional eight. Again there is still another point; the profits derived from the subsequent exploration of A will start to come into the interest market in a year, but with B there is a debit balance accrued to the round sum of $41,767, that is, 7% for 5 years on the price paid for the future possibilities.

As mines with a profitable future are seldom for sale for the net value of their ore reserves alone, a question of future possibilities is as a sequence forced into a calculation against this additional price asked. The geological deductions that have been previously made must be considered in respect to the likelihood of the mine providing a sufficient extension of orebodies to justify this additional price, and at the same time show a compensatory profit on the investment as a whole. This additional price can be calculated in tons of ore which must be expected of similar grade to that produced in the past. It is in this inferential deduction of probabilities that the ability of the engineer is taxed to the utmost. Nothing can be taken for granted beyond the present faces, and the engineer must rely on past experience, training, confidence, and common sense.

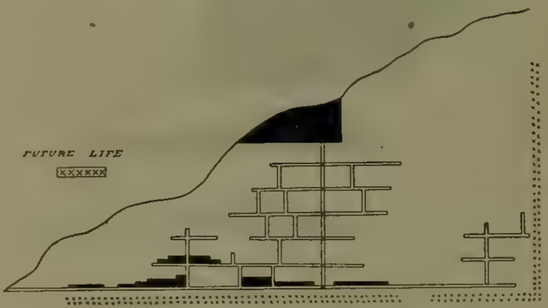

FIG. 4. MINE (D) WITH NET VALUE $700,000.

There are several deductions, though apparently simple in presentment, that are most important. Expectations at depth are an obvious gamble, an engineer examining a property that has only been opened up to a depth of 200 ft. would be taking a positive risk, in the majority of cases, in calculating on a duplicate extension in depth. Should, however, the same property prove a constant producer down to, say, 800 ft. and at that depth the bottom of the mine was still apparently sound, the engineer would be taking a fair chance in counting on an additional 200 ft. In diagram C, Fig. 3, which is the longitudinal projection of a mine developed down to 1400 ft., it will be seen that with the continuity of the orebody a valuating engineer would not be unduly sanguine in hoping for an additional 300 ft. At the same time the engineer must invariably bear all the points in his mind simultaneously and not allow himself to be led away by any individual theory or deduction, for it will be seen that mine C, although a phenomenally strong orebody has been developed already to a considerable depth, and that its exhaustion must be proportionately near at hand.

The lateral extent of orebodies in the majority of cases is some indication of the probability of vertical extension, for the reason that, as a rule, ore-shoots have a greater tendency toward vertical than horizontal inclination. In other words, although they are seldom vertical, they are more inclined to a perpendicular angle than to lying more or less flat. Therefore, if an orebody is 400 ft. long on a certain horizon, it is likely to prove more than that amount in depth and height. This is not to be interpreted as suggesting a known relative proportion between length and depth of ore-shoots. It is merely that the length of a section laterally penetrated by a level is likely to be greater than the minor axis and less than the major axis of the shoot. This deduction probably accounts for the fact that ore-shoots highly inclined from the vertical in respect to the pitch of the shoot in the vein matter, do not, in the majority of cases, descend to depth as favorably as more vertically inclined shoots. It is clear that the more the shoot approaches the horizontal the greater will the horizontal intersection by the level approach the maximum length, or major axis. To those not versed in valuation, the inclination of the shoot must not be confused with the inclination or dip of the vein. What has been written refers to the inclination of the ore-shoots in the vein itself, irrespective of the dip of the vein.

Many important discoveries have been made by closely following the experiences of mines either adjoining or in the immediate vicinity of a property. The recent important discoveries that have been made in Nevada in the course of the last year and a half reflect the greatest credit on the reasoning power and intelligence of those responsible for the discoveries. Depending upon depth or lateral extensions is highly speculative, but the experience in an immediately adjoining property either as to lateral or productive depth of workings has increased the value of a property on sound and fair grounds.

When representing the purchaser the engineer must use his own judgment on the individual case presented. Mines are always drawing nearer their exhaustion, and the duty of the engineer is necessarily a compromise between securing a client's money as far as possible on known values and getting the best attainable speculative possibilities in respect to unknown values. Little headway would be made in mining if valuing engineers and financiers were to allow security to absorb and blot out profit. A young mine with a small ore reserve and excellent possibilities may be a much better purchase than a mine developed to its maximum extent, even though the prices in both cases ahe the same. Mine C, Fig. 3, and D, Fig. 4, represent two entirely different types. Unquestionably C is a mine of decided merit not only as a past producer, but also in respect to known ore reserves. Not only that, but the bottom is as good as it ever was, and the continuity of the ore is phenomenal. The ore reserve is also estimated at $950,000 net. Mine D, however, notwithstanding an ore reserve of only $700,000 is a better purchase, even though the price in both cases is identical. The reason for such a statement is that there is little speculative attraction in C. Its capabilities are known, its lowest level has now arrived at a depth which, in the light of past experience, clearly shows that it is bound to soon approach its exhaustion. It is like a hale and hearty man of sixty-five, strong as ever, but with the laws of average dead against his seeing ninety.

Not only this, but in mine C the daily output is known and its capacity as a maximum producer per day established. There is no chance of increasing the output to reduce the standing charges on the one hand, and bringing its profit into the interest earning market in a shorter time, on the other. Mine D has everything before it. Compare the proportionately longer base line with C. The latter has only a bottom, but D has also a bottom and a side. Also it has the great advantage of permitting gravity work, precluding pumping and hoisting, and has also possible ore extensions on its side, as indicated by the crossed lines in the diagram. As both have the same average thickness of vein it is plain that an energetic development policy would result in an ore reserve that would permit a mill being erected at D of a size that would reduce the daily costs much below those at C, thus making its ore reserve more profitable, grade for grade, and bringing into the region of profit ore zones that C with a smaller output and handicapped with hoisting and pumping charges could not touch.

The inception of the foregoing has not been to instruct; what has been written is done in the interest of perhaps the most complicated and at the same time, vital branches of the industry where many reputations have been made by men who were not optimistic but had the courage of their convictions. Wholesome criticism and exchange of views is in the interest of all concerned. This article has been respectfully submitted to a serious and honorable profession, where the associations of dishonesty which have arisen owing to its latent speculative aspect and which have seldom had origination with those professionally trained, are being steadily eradicated.

Subsidies in Western Australia

To stimulate the deeper development of small mines held by syndicates, the Mines Department of Western Australia has recently made arrangements to pay subsidies on lots of ore from these mines, crushed at any of the State batteries. The payments are made on the following lines: Fifty cents per ton on ore raised from depths of 100 to 110 ft.; 54c. from 110 to 125; 60c. from 125 to 150; 66c. from 150 to 175; 72c. from 175 to 200; 76c. from 200 to 225; and 84c. per ton below 225 ft. The depth will be taken as the vertical depth below the natural surface at the mouth of the shaft or adit, in or from which the said work is performed; and in case of work done from a level, the depth of the level will be taken as the depth thereof at the shaft from which it is driven. Development is to consist of sinking shafts and winzes, driving, raising, and cross-cutting. Shafts must be not less than 5 by 3 ft., raises or winzes, 4½ by 2 ft., or cross-cuts and drifts, 4½ by 2 ft., while any work greater than 6½ by 3½ ft. will be considered as of that size. The amount of waste removed shall be allowed for by granting subsidy on one of ore broken and crushed from any other part of the mine, for each 13 cu. ft. of waste so mined. The regulations stipulate certain forms to be filled in and approved of by a State battery manager, or mine inspector. If that officer is not satisfied with the work carried on, the subsidies may be refused altogether. In a way the payments may be likened to a reduction in crushing charges for some; but for others it will mean a great help in opening small prospects, which often have to be abandoned on account of water troubles at a shallow depth, or the gouging out of the richest shoots as quickly as possible and then abandoning them. In another way it will tend to keep the batteries employed more continuously. At present many mills run for a few weeks and then shut down for a while, which is not an economical way of working a plant of any kind. In a recent address by the Acting Premier at Menzies, he stated that the public batteries had cost to date $3,585,000, and receipts totaled $3,480,000, and that no interest or sinking fund had been paid on the loan money.

TUNNEL LININGS of hard shale brick laid in portland cement mortar have a considerably longer life than stone or concrete linings when exposed to locomotive gases and dampness, according to the observations of M. J. Corrigan, general inspector of tunnels of the Baltimore & Ohio railroad. Soft sandstone in some tunnels has been found to deteriorate in places to depths of 2 in. or more in a year and low-grade concrete also to be rapidly attacked. Coal-mine drainage coming in contact with the lining is observed to be a further source of disintegration.—*Engineering Record.*

Coolgardie and Ora Banda

By M. W. von Bernewitz

Some time in 1910, the Chamber of Mines of Western Australia approached the Government with the suggestion that more geological surveys be undertaken in mapping out various districts, connecting them with known centres, and issuing early reports for the public. Two of these, namely, that of the Coolgardie and the Ora Banda field, by T. Blatchford and C. O. G. Larcombe, respectively, have been issued, while one on Southern Cross, Kalgoorlie, and Boulder is well on the way toward publication. In the Coolgardie field some four miles of country was examined. There are three distinct types of gold-bearing lodes: (1) lodes formed in the fissures of the greenstone and schists; (2) auriferous acid dikes; (3) quartz veins. In the first named class the lodes have been small, and gold has been won from short shoots, which are of little value to the mining industry on the whole, although satisfactory to the small operator. All these mines are now closed. Three of them produced $226,000 from 27,417 tons. In the second class, about three miles from Coolgardie, no less than seven of these dikes occur parallel. Work has been done to 300 ft. depth, but apart from Tindal's and Griffith's mines, the work has been abandoned. Practically all the mines on quartz lodes are closed also; but considerable gold has been won from time to time. Bayley's did from 6000 to 8000 ft. of boring from the surface and 1000-ft. level, but in no case was ore cut. In making recommendations for further prospecting, the geologist suggests that drilling be started in the acid dike at Tindal's from depths of 200 to 300 ft., as that vein has proved to be the most consistent in size and gold content, and horizontal holes would cut at least 6 lodes. If good results were obtained investors would be attracted. The yields from the mines in Coolgardie have produced to date 293,357 tons for $4,115,000. At Bayley's —where gold was originally found—76,402 tons worth $2,125,000 was won. I recently spent a day looking around Coolgardie generally. It is depressing from a mining point of view to see all the batteries silent—even the State mill only works spasmodically—a few dry blowers at work screening the alluvium, of which tens of thousands of tons have been turned over; the once fine plant of Bayley's is idle and rusting away; at the same time, an immense amount of work has been done, as evidenced by the dumps of waste, alluvial diggings, and mill residue. Will the field be busy again? Recent work, and the geologists do not hold out much hope.

The Ora Banda field is 18 miles northwest from Broad Arrow, the latter being 23 miles from Kalgoorlie by rail. The Gimlet centre lies between two ridges, one consisting of coarse-grained amphibolite, and extending for some miles. The amphibolite is derived from a gabbro, and at one place is a fine-grained chloritic rock. In this the same processes of alteration as have been at work in Kalgoorlie may be traced. Granite outcrops about one mile northeast, but there are no mines along the contact, as is common in other parts of the State. There are two belts of schists, one a quarter of a mile wide, between porphyrite and amphibolite; the other between the latter and granite. The latter belt is a mile wide, and along its contact with the amphibolite, which extends some miles, there appears to be a favorable zone for the occurrence of gold in such a way that it may prove profitable to small operators. The chief occurrences of gold are in porphyrite and schist. Large low-grade deposits occur in the former, and judging by the nature of the ore, and observing the deposits below the zone of oxidation, there seems to be no doubt that in this area there is a typical lode formation of a similar origin to Kalgoorlie. The ore is simply the rock changed by the introduction of finely-disseminated pyrite, silica, and other minerals. In the schists, the occurrences should be of value, though not of great extent. There has, in some cases, been a strong movement along the strike of the schists, giving rise to faults, the planes of which have been filled with gold-bearing quartz. Mr. Larcombe concludes his summary by remarking that a zone of porphyrite bounds the west side of the Golden Mile, and the line of amphibolite is almost identical with the amphibolite which forms the north end of the Kalgoorlie field. In fact, it seems more than a coincidence that the succession of rocks at Ora Banda is the same as at Kalgoorlie. When plotted on a map the Kalgoorlie series apparently connects with the Ora Banda series, a distance of some 35 miles northwest. Mr. Larcombe's extensive geologic report on the Golden Mile is now being published by the Australasian Institute of Mining Engineers.

Analysis of Zinc-Dust

Among the many methods of analyzing zinc-dust, the Drewson method, recommended by Paul Speier, is one of the most convenient and most reliable. It is based upon the fact that finely divided zinc reduces a solution of chromic acid (bichromate of potassium and sulphuric acid) without generating hydrogen. The process is carried out as follows: Dilute 40 gm. of molten bichromate of potassium to make 1 litre, and adjust the litre with a strongly acidulated ferrous sulphate solution by means of the ferricyanide of potassium volumetric test. Put 1 gm. of zinc-dust into a glass beaker and pour over it 100 c.c. of the bichromate solution. Add, while gently shaking the beaker, 25 c.c. of diluted sulphuric acid in portions of 5 c.c. each, at intervals of from 8 to 10 minutes. Let solution stand for an hour, and then add another 25 c.c. of diluted sulphuric acid. Then put the whole mixture into a volumetric apparatus and dilute to make about 500 c.c. Then gradually add, while strongly stirring, ferrous sulphate solution (200 gm. $FeSO_4 + 7H_2O + 25$ c.c. H_2O_4 concentrated to 1000 c.c.) until one drop with ferricyanide of potassium solution produces a weak but distinct blue coloring. In order to determine the quantity of the metallic zinc contents, the cubic centimetres corresponding to the iron solution which has been used have to be deducted from the bichromate of potassium solution, and the bichromate of potassium contained in the remainder has to be multiplied by 0.66113.

Mining Taxes in Colombia

The mining law now in force in Colombia provides that the denouncer of a gold or silver mine shall pay to the treasury department of the Federal Government before making the denouncement, the sum of 50 centavos, and shall be charged $4 gold for the title to each mine. Every gold or silver mine having veins of these ores shall pay $1 gold, annually for each claim or *pertenencia*, and such mines containing more than one *pertenencia* are subject to annual taxation at the same rate for each additional *pertenencia* or fraction thereof. Mines containing less area than a *pertenencia* must pay taxes at the same rate charged for one *pertenencia*. Denouncements made and mining titles issued in accordance with the provisions of the mining code do not require internal-revenue stamps to insure their validity. Owners of mines to which titles have been issued and which are not in litigation may, by paying at one time double that which they would have to pay in twenty years in accordance with the code of October 21, 1867, insure permanent ownership thereto and thereby become exempt from further taxation in the future or from registration or denouncement by anyone. Whoever denounces a mine without taking the necessary steps to complete the formalities required by law, within one year from the time of making the denouncement, forfeits his rights to the mine which thereby becomes abandoned and subject to denouncement by other parties. The location of mines in the beds of navigable rivers or streams is prohibited. The provisions of the fiscal code govern concerning coal mines and asphalt deposits, oil wells and natural gas, and no concession for the exploitation of these will be valid without the approval of Congress.

Storing Drill-Cores

By A. H. Meuche

*Another matter which has become a sort of hobby of mine is the care and preservation of drill-cores. Perhaps this is due to the fact that I have examined in the neighborhood of a hundred thousand feet of drill-cores during the last few years. I have seen cores kept in a limited number of boxes; when these boxes became full, the cores were dumped out and the boxes refilled. I have seen core-boxes kept in a cold, wet cellar, one box piled on top of another, forming a high stack. Often the lids are nailed down tighter than the bottom is nailed to the box, so that in trying to pry off the lid the box falls to pieces. I have climbed upon racks, pulled out boxes (not having covers) that were slipped in sideways, balanced them on my finger tips and tried to get down. Once or twice the boxes turned upside down.

With these experiences you can readily perceive why the method used by the Victoria Mining Co. and later adopted, with some minor changes, by the Mass Consolidated Mining Co., appeals to me. In both cases a sort of cabinet has been built, using the core-boxes without lids as drawers. The boxes slide lengthwise into a rack or cabinet. The boxes or trays are stacked so close together that the bottom immediately above acts as its cover. At the Victoria, a strip the full length of the box is nailed on either side, forming the slides for the drawer. A drawer-pull and a label giving the number of the hole and the depths of the hole from which the core was taken are fastened to one end of the box. At the Mass mine the necessity of nailing strips to the sides of the box has been overcome by allowing the bottom of each box to extend about half an inch on either side. The boxes are made about 5 ft. long, which is a convenient length to handle, and hold enough core for ordinary purposes. The cabinet itself is made similar to any ordinary cabinet, holding drawers, except that it is not necessary to put a piece of wood under each drawer as a stiffener. If the sides are made of two-inch material, a stiffener need only be introduced about every ten boxes. Sides or partitions are made for each stack of core-boxes and as high as desired. These had better be made pretty heavy, as they must support the entire weight of all the boxes in each stack, and in order to make the construction as slow-burning as possible, I would suggest a tight partion. Strips are nailed on both sides of these partitions to catch the strips on the boxes, thus supporting them. These strips should be placed just far enough apart to allow easy and free sliding of the boxes.

The accompanying sketch (Fig. 1) will explain the construction fully. The advantages of this system are the convenience in referring to the cores at any time and small amount of space required. Each box occupies a space of 10⅞ by 2^3/$_{16}$ inches. Allowing one stiffener for every 10 boxes, 30 can be stored in a stack 5 ft. 9 in. high. As each box holds 30 ft. of 1⅛ in. core, which represents approximately 40 ft. of drilling, one stack would represent 1200 ft. of drilling. Ten such stacks, representing 12,000 ft. of drilling, would only occupy a space 6 ft. high, 10½ ft. long, and 5 ft. deep. I do not believe that the same number of boxes with covers screwed on could be gotten into the same space, and I question if the lumber and screws used for a cover would cost as little as would this cabinet. The only objection to the scheme is the trouble involved in transporting the boxes from the drill. The Mass Mining Co. solved this by making boxes with hinged covers and locks which would just hold one core-box. The core-box was then placed in the box, which was then locked and sent to the mine office. For shipping, the core-boxes could be crated readily enough.

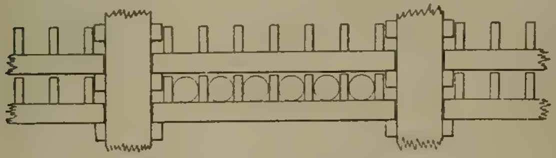

FIG. 1. SKETCH SHOWING BOXES IN RACK.

I wonder, with such a convenient method as this of storing cores, if as much core would be thrown away as is now done. After so much money has been spent in obtaining the records, it seems too bad to see the true records destroyed. I often encounter the argument, "Of what good are they?" They usually are no longer of any use to the company, but some one else may examine them and see something of great scientific or practical value. There is some excuse for a person holding merely an option on a piece of land to throw away the cores, as he may not have any place to store them, but in those cases I truly believe that the Geological Survey should make an attempt to preserve the records.

---

*Abstract from a paper on 'Some Practical Suggestions for Diamond-Drill Explorations,' read before the Lake Superior Mining Institute.

Copper Producers' Statement

The Copper Producers' Association August statement shows a decrease during the month in accumulation in this country of 4,297,357 lb. The details are as follows:

	Pounds.
Stock of marketable copper of all kinds on hand at all points in the United States August 1, 1911	137,738,858
Production of marketable copper in the United States from all domestic and foreign sources during August	125,493,667
Deliveries of marketable copper for consumption and export during August	129,791,024
Stock of marketable copper of all kinds on hand and at all points in the United States September 1	133,441,501

August production and deliveries for three years may be compared as follows:

	Production.	Deliveries.	Surplus.
August 1911	125,493,667	129,791,024	*4,297,357
August 1910	127,803,618	129,563,051	*1,759,433
August 1909	120,597,234	107,996,911	†12,600,324

*Decrease. †Increase.

August exports and domestic deliveries for three years has been as below, in pounds:

	Exports.	Domestic deliveries.
1911	69,855,660	59,935,364
1910	61,831,780	67,731,271
1909	48,382,704	59,614,207

The changes in surplus since January 1, 1911, have been as follows, in pounds:

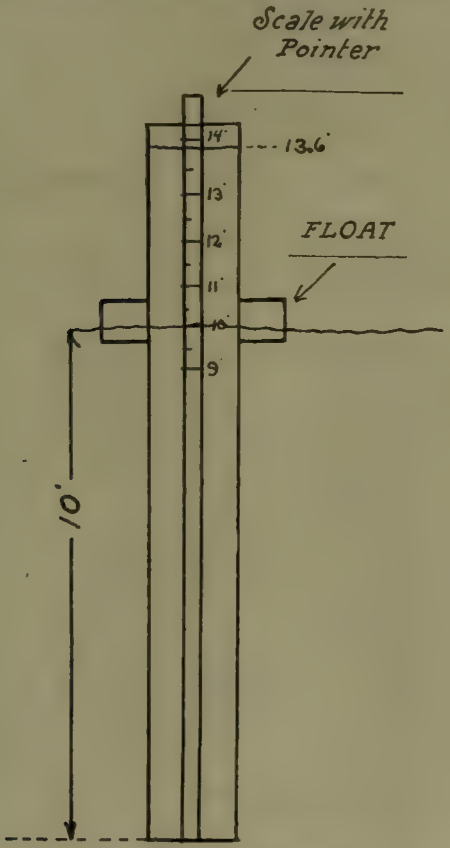
	Increase.	Decrease.
January	20,409,295	....
February	14,198,280	....
March	5,370,164	....
April	3,547,974	....
May	440,024	....
June	....	8,561,768
July	....	19,695,306
August	....	4,297,357

L. Vogelstein & Co. report the following figures of German consumption of foreign copper for the months January to July 1911, inclusive: Imports of copper, 106,077 tons; exports, 4928; consumption, 101,149. The corresponding consumption during the same period in 1910 was 95,092 tons. Of the above quantity 91,771 tons was imported from the United States.

Measuring Specific Gravity in Agitators

By Charles F. Spaulding

Take a piece of 3 or 4-in. pipe some 14 ft. long. Sink it in the agitating-vat so that the lower end of the pipe will be exactly 10 ft. below the surface of the pulp. Measure the height of the solution inside the pipe (in feet). This divided by ten will give the specific gravity of the pulp. For example, suppose that the lower end of the pipe is exactly 10 ft. below the surface of the pulp and that the solution in the pipe stands 3.6 ft. above the surface of the pulp, or 13.6 ft. above the bottom of the pipe. This measurement divided by 10 gives 1.36 as the specific gravity of the pulp. If it be desired to refine the measurements, the scale can be calibrated according to the specific gravity of the cyanide solution instead of feet and tenths. This is based on the fact that the inside column must balance the outside column. The weight of the inside column is the area by height by weight of a cubic foot of solution. This must balance the weight of the outside column, which is area by height by weight of a cubic foot of solution times the specific gravity of the pulp. Eliminating the equal factors in the above and having the pipe 10 ft. deep, the matter is reduced to the height of the solution in the pipe, measured in feet, divided by 10, this giving the specific gravity of the pulp. The pipe could be arranged on a float so that the bottom of the pipe would be 10 ft. below the level of the pulp in the vat. A small float with a pointer could be placed inside the pipe. The whole arrangement could be placed inside the vat and left floating around. The pointer would indicate the specific gravity at any time. This would be especially advantageous in continuous agitation, one specific gravity tester in each tank. If the ore foams badly a shield 12 to 18-in. diameter placed around the pipe will allow the operator to see the surface of the pulp in the tank.



SPECIFIC GRAVITY TESTER.

Copper Production of New England

By A. L. Sweetser

Few people realize that the first copper mine in the United States was developed at Granby, Hartford county, in the State of Connecticut, in the year 1705. In the following year the Bristol mine in the same State became the second producer of copper in the United States. Both of these mines were developed in a fault zone between gray gneiss, hornblende schist, and Triassic sandstone. The Loudville mine, in western Massachusetts, was also in active operation before the Revolution of 1776 and produced lead, silver, copper, and zinc, the minerals being found in veins of quartz traversing trap rock and gray sandstone. The rusty colors of the pre-Cambrian rocks of New England, especially in the upper strata, early induced prospecting, and considerable digging was done at various places long before the Revolution. No authentic records exist of the production of these mines previous to 1880, at which time the United States Government published the mineral statistics on the production of the various States. This continued until 1885, after which date only the total production of New England has been given. From these bulletins and the individual reports of each State the following tables of the copper production from 1880 to the present date have been compiled:

Pounds of Refined Copper Produced from 1882 to 1885

State.	1882.	1883.	1884.	1885.
Maine	125,000	98,000	100,018	45,000
New Hampshire..	165,000	114,000	149,000	55,000
Vermont	1,265,000	400,000	655,405	111,602

Pounds of Copper Produced in New England from 1882 to 1911

1882	1,555,000	1897	72,017
1883	612,000	1898	95,226
1884	904,423	1899	110,554
1885	211,602	1900	80,495
1886	315,719	1901	60,039
1887	200,000	1902	45,047
1888	271,631	1903	55,612
1889	172,000	1904	36,086
1890	378,840	1905	34,960
1891	296,463	1906	21,438
1892	467,448	1907	6,311
1893	432,793	1908	188,756
1894	374,514	1909	197,044
1895	105,036	1910	190,600
1896	104,993		

In 1877 there was a copper boom in Maine. At this time the Blue Hill and Sullivan mines attained great prominence. These were large producers until 1884, when they were closed because of the low price of copper. In these mines the copper occurred in small veins traversing slate and gneissic rocks. The Davis pyrite mine in Franklin county, Massachusetts, has worked steadily since 1880, and at Sheldonville, in Norfolk county, Massachusetts, a copper mine was opened in 1901 on a quartz vein in granite, carrying gold, silver, and copper. For many years several properties in Grafton county, New Hampshire, have been steady producers, in a small way, the ore being found associated with blende and pyrite in fissure veins. In Vermont copper ore occurs in quartz veins in talcose slate and also in pockets of mica schist. The chief mines are in the counties of Lamoille and Orange. Previous to the development of the Lake Superior district of Michigan, Vermont was an important source of copper. The Elizabeth mine, opened in 1793, is the oldest in the State. In 1821 the Ely mines were the largest producers. They have been worked to a depth of 3600 ft. At the present time the most important copper producer is the Union mine.

Direct fusion of ore containing 25% sulphide and 7 to 11% mispickel gives 90% of the gold on the first fusion. The remainder may be obtained by re-fusing with more flux.

Discussion

Readers of the MINING AND SCIENTIFIC PRESS are invited to use this department for the discussion of technical and other matters pertaining to mining and metallurgy. The Editor welcomes the expression of views contrary to his own, believing that careful criticism is more valuable than casual compliment. Insertion of any contribution is determined by its probable interest to the readers of this journal.

Positions Wanted

The Editor:

Sir—I should like to announce to those interested that the work of acting as a clearing house between the employer and the employee, which I assumed on the departure of Mark Lamb for South America, has been taken up by the American Metallurgical Society.

RAYMOND C. BENNER.

University of Arizona, Tucson, August 31.

Air Hammer-Drills

The Editor:

Sir—In your issue of August 19, page 237, under the heading of 'Concentrates,' is an item referring to air hammer-drills, in which the statement is made that they are adapted only to drilling uppers. While I infer that this statement has reference only to stoping drills or what is known as air-feed hammer-drills, still it is misleading. As you are aware, Water Leyner drills are air hammer-drills, and there is no limitation to the direction in which holes may be drilled with them. The type of drill in question might have been more clearly defined.

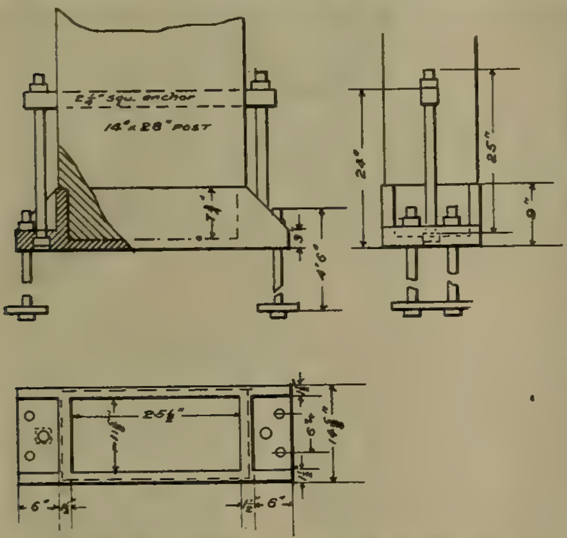
C. A. HIRSCHBERG.

Littleton, Col., August 24.

Securing Battery Posts

The Editor:

Sir—In the issue of August 26, F. W. Sewell describes the battery-post shoes in use at the Guanajuato Con. M. & M. Co., and to their simplicity I wish to take exception; I admit their solidity and strength, but wish to criticize their unnecessarily heavy proportions and expense. The core and mill-work must have entailed a large sum for the casting and finish; the extra framing, necessitated by the round and taper ends as well as that for the seating of the two brackets and the five bolt holes, is expensive; the freight and cost of handling into place must have been high.



BATTERY-POST SHOES AT BLACK MOUNTAIN MINE.

Let me call attention to the battery-post shoes erected in 1905 in the 120-stamp mill of the Black Mountain M. Co., at Cerro Prieto, Sonora, Mexico. The battery posts were 14 by 28 in.; the weight of the shoes 510 lb., held down by two 1¼ in. by 4½ ft. bolts at each end, with plate washers imbedded in the concrete mortar block base. 1½ by 25 in. bolts are passed through the shoe with a square head in the recess in the underside of the shoe, and through the 2¼ in. square anchor bar in the battery post itself. I admit that, in case one of these bolts broke, it would be troublesome to replace. But, with the exception noted, the Cerro Prieto design has every advantage over the other; less weight without loss of requisite strength, simpler design, and less framing necessitated. After five years run, no failure of the shoe or post anchors was noted. If the wood for the posts be well seasoned, there would seem to be no excuse for a driving fit into the shoe, as described by Mr. Sewell.

K. BAUMGARTEN.

Tucson, Arizona, August 29.

Overvaluation of Prospects

The Editor:

Sir—In your issue of August 12, 'L. L.,' in criticizing a former article of mine, lays especial stress on the consideration of time, place, occurrence, and metallurgical environment in the valuation of prospects. When I stated in the article in question that the ore must be of a grade to pay a reasonable profit over all expenses, I of course assumed that the above considerations were fully taken into cognizance, as without so doing no reliable valuation can be made. That the unprofitable ore of today might become profitable tomorrow is not denied, but the future possibilities of transportation or metallurgical progress can hardly be considered as a factor in an investment where reasonably quick returns are expected. It is also immaterial whether the ore is exposed 100 ft. high or 100 ft. deep. It is the amount of ore exposed, and not the type of deposit, that is one of the governing factors. Bedded deposits, as at Joplin, and porphyry coppers may possibly be an exception, but even here, to learn the true nature and occurrence of the orebodies it required considerable exploratory work by shafts and drifts, before any dependence could be placed upon drill-holes. That the majority of the big mines of the world had surface showings of pay-ore must be self-evident, as without this no deep work would have been undertaken in an unproved district. However, this being so would not justify the investor in paying the price of a mine for a cropping of ore, since no less an authority than Daniel Guggenheim states that only 1 out of 200 prospects showing ore at the surface ever becomes a mine.

R. L. MANN.

Cazadero, August 28.

Cross-Fractures and Ore-Shoots

The Editor:

Sir—In these days of practically having to first find your own mine and then to develop it, the subject of 'Surface Indications of Ore-Shoots' is a vital one. I had hoped that the theme would bring out a larger 'blossom.' Mr. Storms has made a good case in voicing the miners' desire, born of well founded empiricism, to 'get into the heart of the hill.' Of course Mr. Storms or anyone else would nevertheless keep an eye out for ore in the gulches. The tarrying 'At the Sign of the Hill' has been pleasant, but with the hope that the quest may be continued and that I may not fare like the late Mr. Pickwick, I would like to submit the question of 'cross-fractures as indications of ore-shoots.'

I do not recall that this subject, by itself, has been discussed in the literature of ore deposits. At any rate, I do not think it has been sufficiently emphasized. I refer to the minor fracturing or seaming or plating that often locally develops in a direction more or less across that of the main line of deposition, be this in fissure-vein, shear-zone, or contact-metamorphic type of ore deposit. (Using the latter term in common parlance, and not in the restricted sense of the 'true contact-deposits' of the U. S. Geological Survey.) I am not directing these remarks as much to that sympathetic shearing which often accompanies cross-faults and intersecting veins, as to those independent zones or patches of cross fracturing that often occur along the general course of deposition. This fracturing may penetrate either or both walls or may develop only in the vein filling; it may accompany wall-grooving but not always. The frequent occurrence of such cross fracturing in connection with ore-shoots has so impressed me that I now intuitively look for it as I would for the presence of zinc where native silver occurs. The fractured areas are probably due to various causes: later movements, folding of the rocks, etc., both cases being the expression of local relief of strain.

As to their control over ore deposition I would suggest action similar to that of 'pressure phenomena.' The Cerro de Plata prospect in northwestern Sonora, is a type of silver deposit closely related to jointing, which is here regional. Perhaps in cases where the cross fractures are strong and extend down through the country rock they may serve the same purpose as 'verticals.' J. E. Spurr, in his first work on the Tonopah deposits (Prof. Paper No. 42, U. S. Geol. Surv.) calls attention to cross fractures, and, as I remember it, speaks of them as acting like walls to the mineral solutions, the quartzose filling suddenly jumping to greater width at the place of meeting and gradually narrowing down to normal width again. W. Lindgren, in his 'Metasomatic Processes in Fissure Veins,' ('Genesis of Ore Deposits,' Amer. Inst. Min. Eng., 1901, page 556), speaking of the influence of small cracks and fissures on replacement, says: "Generally, however, the replacement process proceeds irregularly, owing to the effect of little cracks and fissures. Short clay seams may often interpose an absolute barrier, so that sharp contacts of replaced and fresh rocks results." This is beautifully illustrated at the Promontorio copper mine, in central Sonora. S. F. Emmons ('Downtown District of Leadville,' U. S. Geol. Surv. Bull. 320, page 71), says: "It is evident that the fractures across the limestone have played an important part in fixing the location of orebodies and in furnishing channels along which the ore-bearing solutions may pass from one horizon to another, but the general impression produced upon the mind of the writer has been rather that they serve to divert or temporarily arrest horizontally moving solutions (especially where, as can sometimes be proved, they are the final results of a strain that produced folding) rather than to afford continuous channels for solutions moving directly upward."

Recalling some of my personal observations and depending, in some cases, on memory, I might mention the Blair mines, at Silver Peak, Nevada. While having charge of the field work on an examination that extended over several months, during which time we did some drifting 'feeling out' the ore, I tried to find a reason for the sudden stopping of ore to the west in the Wasson Tunnel workings. This ore-shoot zone, in all probability, is the same as shown in the Drinkwater workings above. However, there was solid ground for several hundred feet between, and I have no later data confirming this. Cross fracturing is prominent both above ground and below, but ore does not always accompany the cross fracturing, at least above ground. In the Wasson workings I could see by the magnifying glass, absolutely no difference between the pay and the barren quartz, except that the pay ore was cross fractured. The quartz was apparently the same, as were also the scattered crystals of pyrite and galena, only that these latter assayed very high within the pay zone and quite low outside of it. The amounts of these sulphides were practically the same in either case. The cross fracturing here has a dip to the west, which, if the Wasson pay zone is the downward extension of the Drinkwater, would make the shoot zone pitch across the dip of the cross fractures.

In the case of the Belmont vein, at Tonopah, I have in my notes that the cross fractures on the seventh level dip to the northeast, and are more prominent in the foot wall. I do not know the pitch of the ore-shoots here. In the Mizpah vein, sixth and seventh levels, the cross fractures seem to greatly influence the deposition of the ore, the quartz being the widest on the lower side of the fractures. I failed to note the direction of dip of these cross fractures, nor do I know what may be the pitch of the shoots. These notes were taken during a hasty trip through, hence are incomplete.

The Rosedale gold mine, in New Mexico, affords a good example of ore-shoots pitching across the dip of the cross-fractures. Here there are two shoots, apparently approaching in depth, with cross fractures in each shoot dipping oppositely. The Coronado fault vein, at Morenci, Arizona, is strongly cross-fractured on the surface. I know nothing about things underground there from personal observation. I have been told, but not authoritatively, that at the King of Arizona mine, Yuma county, the hunt for a new lens of ore is guided by the cross fracturing of the formation.

My observation has been that where cross fractures exist, the shoot pitches, more often than not, across their dip, at least near the surface, and perhaps in about the same ratio as in normal and reverse faults. In advancing this idea I am running counter to what would seem the natural pitch that the shoot should have, and even narrowing the question of dip down to wall groovings alone, the impression that I have of it is that the shoot dips across rather than with the groovings. The suggestion, however, comes up that this might be modified by the relative age of the grooving and the present pay ore, the original grooving that marked the first line of movement having probably been obliterated by later movements. J. F. Kemp ('The Problem of the Metalliferous Veins,' *Econ. Geol.*, Vol. 1, No. 3, 1906, page 219), says on this subject: "The usual experience reveals the ore running diagonally down in the vein filling, and more often than not following the polished grooves in the walls which are called slickensides, and which indicate the direction taken by one wall when it moved on the other during the formation of the fracture." Personally I would make the distinction between slickensides and wall groovings more emphatic, the former, as exhibited on wall gouge *may* be found to have any direction, on digging into a thick gouge.

This question of the relation of cross fractures and ore-shoots would be made clearer, and probably practical help would result, if those who are in a position to do so would map the points involved. In cases where local patches of cross fracturing occur along the strike and dip of veins, it might throw light on the subject were these patches plotted, showing their local dips, in relation to the ore-shoots.

Returning again to cross fractures as indications of ore-shoots, it may be that such fractures in some cases impoverish the vein, but even so, another portion has probably been enriched, and as a general proposition I would rather have the cross fractures present.

W. N. CUMMINGS.

Tucson, Arizona, September 2.

HAMMER DRILLS are used at the Ray Consolidated copper mine in Arizona in the drifts and have on test permitted more rapid advance than with piston drills, according to *Mines and Quarry*. The method is as follows. After a shot, the driller puts in his upper holes from the top of the pile of broken rock while the shoveler is at work loading. The lifters are therefore put in last, when the waste has been all removed. The rock consists mainly of schist, with some limestone, and would be classified as 'fairly soft.' From April 5 to May 1, 25 days, a crew of one drillman and one shoveler, using a Sullivan DB 15 tool, advanced a 4 by 6-ft. tunnel 254.5 ft. The cost of labor and supplies on the machine amounted to $1.54, or $0.006 per foot of tunnel. The DB 15 tool weighs 25 lb., uses 7/8-in. hollow steel, and consumes about 20 cu. ft. of free air per minute at 90 lb. pressure. Another method employed at this mine for driving is to drill the upper holes with an air-feed stoper, and the down holes with the hand-feed tool. The great advantage in using hammer drills in work of this class, as in stoping, consists in the fact that no time is lost in removing the broken rock before beginning drilling, as in the case of piston drills, or in mounting the drill afterward on the bar or column. Holes can be placed at just the point and angle required to break the rock properly, with the least amount of drilling and the smallest quantity of explosive.

Concentrates

Most of these are in reply to questions received by mail. Our readers are invited to ask questions and give information dealing with the practice of mining, milling, and smelting.

LIME hardens on filter cloths when the presses stand unused, and this leads to slow leaching and high tailing. The remedy is acid treatment of the cloth.

ASBESTOS in its highest development is not only fibrous, but its fibres have a high degree of flexibility and a good degree of tensile strength and elasticity. Furthermore, it is incombustible, being thus strongly contrasted with organic fibre and rendered most valuable for fireproofing.

STANDARD SPECIFICATIONS have been prepared by the American Society for Testing Materials for structural steel; special plate and rivet steel; building, bridge, and ship material; concrete reinforcement bars; forgings, axles, and wheels; structural nickel steel; and many other products. These have been adopted by the Association of American Steel Manufacturers and govern the steel trade of the United States.

FIRE FIGHTING in the mine is complicated by the low head-room. It is impossible to carry water far from the nozzle because no adequate elevation can be secured even with considerable pressure. In a seven-foot adit, for example, under 40 lb. pressure the jet can only reach 34 ft. from the man. Any sort of a fire of consequence is too hot to allow a man to go within this distance of it. Again, the irrespirable air prevents effective fighting unless the fighter dons oxygen helmets, or is supplied with fresh air from behind him.

FIRE-CLAYS require more than analysis to determine their availability for manufacture into fire-brick. The tests made include also the refractory test, and determination of porosity before and after burning at cone 12. According to the use to which the brick is to be put, other and supplementary tests are necessary. These include resistance to abrasion (for the top of blast-furnace linings); ability to carry loads at furnace temperatures; heat conductivity; specific heat; resistance to sudden temperature changes; and numerous others.

WATER is found in some amount in all formations below the earth's surface, from the loosest and most porous sands and gravels to the hardest slate and granite. The amount varies from the merest trace chemically combined in the molecules of the rocks to immense reservoirs which supply wells flowing hundreds of thousands of gallons a day. Some waters are so pure that a refined chemical analysis shows only minute traces of organic and mineral matter; others are so heavily charged with minerals or other impurities as to be unsuitable for use.

THE compressive strength of timber is much greater than its transverse strength, and a seasoned long leaf yellow pine log 10 in. in diameter and 9 ft. long used as a post will sustain safely a load of 63,270 lb:, whereas the same log used as a beam will carry only 8250; and yet the usual method in timbering mines is to make the legs and collars the same size. It is convenient to do so, and details of wooden framing are such as to make that method of construction desirable; yet the extra amount of material that goes into the legs is usually wasted. In swelling ground the full strength of the legs may ultimately be developed and squeezes caused by adjustment of stresses under geologic forces may impose upon them loads which they may even be unable to sustain.

MEN working around gas apparatus should be free from any disease of the heart or lungs. It is especially dangerous to expose one overcome by gas to cold, by reason of the difficult heart action. The muscular weakness which comes from gas poisoning, particularly in the legs, may appear without attracting notice, so that the person affected may be unable to escape. The gas engine should never be placed in a confined space, or in a basement. If doors are required to the engine room, they should be cut away at top or bottom, or both. The exhaust pipe or vent should never be inside a building, but always outside, and more than six feet above the ground level.

BLASTING in wet or cold weather involves many difficulties, such as water in bore holes, necessity for hurry, and so on. It not infrequently happens that electric fuse wires are stripped or broken in tamping, connections are improperly made, poorly insulated and leaky, or the circuit is broken or interrupted in some other way which results in the misfire of the explosives in some or all of the bore-holes, causing serious loss and delay. In order to eliminate this trouble as far as possible, a 'galvanometer' has been designed for testing the blasting circuit before firing. It is possible with this instrument to detect a break or leaks of any considerable extent in the blasting circuit, and also to detect serious defects in the electric fuses and determine the point at which the troubles exist.

TIMBER preservation treatment has been applied to both square and round timbers of Douglas fir when used in permanent mine work. The treatment generally consists in impregnating the wood with creosote, but carbolineum and zinc chloride have been used. Round timbers are easily treated, because the soft sapwood readily absorbs the fluids. The wood should be peeled clean of bark before treatment. In the square form, the impregnating of Douglas fir with preservative fluids has never been entirely successful, because the density of the heart-wood hinders the penetration of the preservative. Of late years, however, considerable progress has been made in developing a successful treatment of Douglas fir heartwood by the boiling process, followed by pressure.

FEEDING the large stamps now used in South Africa has introduced some peculiar problems. It is not always convenient to build, and especially to re-build, ore-bins of sufficient capacity immediately back of the stamps, and continuous feeding of ore, as by conveyor-belts, is impossible because the action of the stamps is irregular. Hans Behr has applied for patents covering two systems designed to meet these difficulties. In the first a conveyor belt delivers to each mortar a continuous stream of ore somewhat less in quantity than that demanded by the stamps. The deficiency is made good by ore delivered in the ordinary way through automatic ore-feeders. According to the other scheme the belt delivers to the mortar the full amount of ore, but its speed is regulated by electric resistance brought into play automatically when the mortar is full. This second plan would necessarily require a separate delivery belt for each mortar.

EXPLOSIVES of many different compositions are now on the permissible list of the U. S. Bureau of Mines, but all have been formulated with a view to producing explosives which on detonation give a relatively low flame-temperature of short duration. It has been found that in order to ignite inflammable gas and coal-dust mixtures, a certain temperature, acting through a certain length of time, is required. It has also been determined that the temperature on detonation of all explosives exceeds the ignition temperature of inflammable gas and dust mixtures, but, fortunately, the flame of the permissible explosives is of such short duration when properly detonated, that the requisite time necessary for igniting the inflammable mixtures does not obtain. It is evident that any factor that increases the duration of the flame-temperature of a permissible explosive, such as the use of a weak detonator or the use of any explosive not in accordance with the provisions prescribed, will increase the danger in their use.

Special Correspondence

NEW YORK

Market Depression Continues.—English Capital to Invest.—Copper Curtailment and Production.—Arizona Commercial and Superior & Boston.

Under normal conditions, the celebration of Labor Day marks for Wall Street the close of the vacation season and the time for resuming the serious occupations of the year. Vacations have been as generous and as universal as usual, but the market slump of the month just past has engendered a spirit of all-pervading pessimism. The Boston copper market is upset by the attempted consolidation of the Calumet & Hecla and further by the appraisal of the Michigan mines by J. R. Finlay at 60% of the present depressed market price. American interest in precious-metal mining, at least so far as the Eastern share-markets are concerned, has been given mostly to Mexican or Canadian properties since the Nevada mining boom. In both of our neighboring countries conditions have taken an untoward aspect. Political quiet in Mexico is far from assured, and in Canada the situation is little better. Porcupine suffered by being absurdly overdone.

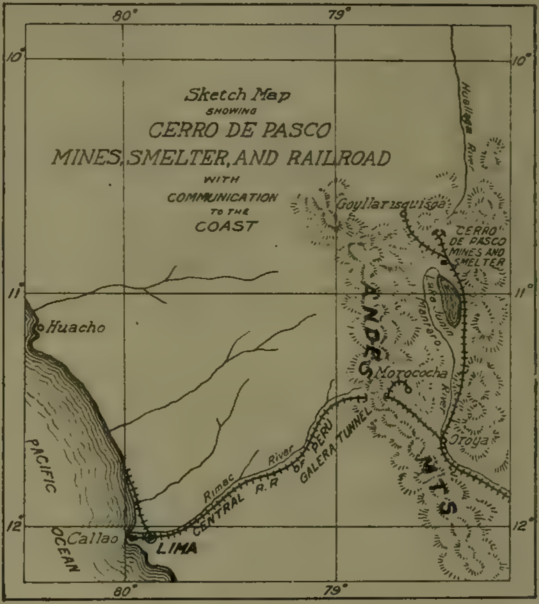
One important move that may mean something tangible for the development of the Canadian mining fields, is the recent organization of the Anglo-French Financial Company of Canada, with a nominal capitalization of two and a half millions. The president of the company is Frederick Baker, head of the Venture Corporation, which developed the Esperanza, Ltd., at El Oro, Mexico, and bought the Camp Bird from the late T. F. Walsh. Mr. Baker is also a director in the Hirsh Syndicate and the Lena Goldfields. The vice-president is Norton Griffith, head of a large contracting firm which has carried out some of the most difficult railroad construction in the world. The remaining officers and directors are prominent in banking and Stock Exchange circles in London. The president and vice-president are expected to sail for Canada during the current month, and to look over the field with a view to taking up railroad and mining projects.

The reports of the largest copper producers for the month of August show little attempt at curtailment. The Phelps-Dodge output for the month of August is given as 11,349,904 lb., which is larger than for any previous month in 1911. The Calumet & Hecla output for August is 11,374,064 lb., which compares with 10,551,847 in July. The only month in which this figure was exceeded was in April, when the total was 11,515,859 lb. The Anaconda turned out 22,500,000 lb. for August, a greater output than has been made in any one month this year. The Butte-Ballaklava has resumed shipments after being shut down for nearly a year on account of litigation with the Anaconda. It is said that there is to be another attempt at a curtailment agreement, but curtailment, like charity, begins at home and is apparently as rare.

The plans for the consolidation of the Arizona Commercial and the Superior & Boston have been announced. The former is a promotion of N. L. Amster, who was caught in the recent slump and was obliged to relinquish control of his various properties. The latter is one of the important new properties at Globe. The merger is to be effected by an issue of 350,000 shares of stock, par value $10, by the Superior & Boston; 200,000 shares of this stock, $5 paid in, is to be exchanged for $1,000,000 outstanding bonds of the Arizona Commercial. The consolidated company will later make a bond issue of $600,000 and Arizona Commercial stockholders will be given the right to take these bonds at par. The subscribing shareholders will receive one share of Superior & Boston for each two shares of Arizona Commercial. The deal is to go to a Boston banking house, and is to become effective upon its acceptance by three-fourths of the Arizona Commercial bondholders.

The market in Tennessee Copper has improved, reflecting better conditions. The directorate has been strengthened by the election of Horace M. Kilbourne, one of the vice-presidents of the National City Bank, Victor Sutro of Sutro Brothers, and Herman A. Kellar to seats on the board. Tennessee Copper now claims to have the largest sulphuric-acid plant in the world and is producing 500 tons daily, which output is to be much increased in the near future.

The copper producers are inclined to look upon the August statement of the Producers' Association as something of a triumph. Notwithstanding the heavy output for the month, a decrease of 4,297,357 lb. in accumulated stocks is recorded. It is still the export demand that is saving the situation. While, in a way, the tremendous foreign consumption bolsters the metal market, it is unfortunate that domestic manufacturers are not in a position to take advantage of cheap metal. When constructive enterprise again gains headway in this country the metal market will advance, and by the same token, our domestic consumers will be caught coming and going. For the present the consumer abroad is making the most of a good thing, and Americans are rather helplessly aiding and abetting him therein.



The Cerro de Pasco is said to be in a position to start dividend disbursements, and to begin to return to its owners the large amount which has been expended in its development. J. B. Haggin is the principal figure in a group of wealthy men who have contributed the 18 or 20 millions which have been spent upon the property. The others are J. P. Morgan, H. C. Frick, the Hearst Estate, the Estate of the late D. O. Mills, and one or two others. The ores go to the Baltimore refinery of the Guggenheims, and, for the year ended June 30 last, yielded 48,600,926 lb. of copper. W. A. Clark is again in receipt of his regular monthly 75c. per share on the stock of the United Verde Copper Co. Owing to subsidence of the ground under a part of the smelter and the necessity of extensive repairs, payment of one dividend was omitted. United Verde is a close corporation, so close, in fact, that when a speculator bought 500 shares of stock at auction some months ago, in the belief that he could make a quick turn, he was surprised to learn that he had made a permanent investment. For some reason Mr. Clark apparently had no bid to make for that particular block of stock, and the owner has had considerably more capital than he desires tied up in United Verde.

A special meeting of the American Institute of Mining Engineers will be held August 29 to formulate amendments to the constitution to be voted on at the regular business meeting of the Institute next February.

MEXICO

Oil Production Increasing. New Railway Lines.—Conchos Reservoir. Taviche Shipments

Mexico is rapidly assuming importance as an oil producer, and oil men realize that its production during the next few years probably will have great bearing on the oil markets of the world. The present wells in what is generally referred to as the Tampico district—principally in the State of Veracruz, south and west of that Gulf port—are capable of producing fully 200,000 bbl. per day, and present development promises a big increase in the possible production during the next year. By the end of this year the Huasteca Petroleum Co., a Doheny concern, will have storage for 10,000,000 bbl of oil, through the completion of 100 additional 55,000-bbl steel tanks. These tanks are being erected about four miles distant from the company's tank farm on the Panuco river at Tampico, where there are 65 steel tanks of the same size, and a concrete reservoir holding 850,000 bbl. Materials for a second pipe-line from the company's Juan Casiano field to Tampico have arrived at the port. The Texas Oil Co., which is getting ready to export to the United States, is preparing to build pipe-lines from the tank farm it will establish to producing fields. The Electra Syndicate, of London, has brought in a well at less than 2000 ft. in the Topila field, where the East Coast Oil Co., a Southern Pacific concern, recently brought in a gusher. The Pearsons are rushing pipe-line and storage work in an attempt to take care of the production in the Potrero field.

CONCHOS RIVER, IN CHIHUAHUA, MEXICO.

English capitalists are reported to be considering the building of a railroad from Zacatecas, or some nearby point on the Mexican Central line of the National Railways, to the Bolaños district in the northern part of the State of Jalisco. Such a line would result in a mining revival in that old district, at one time among the most important in Mexico. The Mexican Mines Co., organized by the Bradbury interests of Los Angeles, California, after their purchase, last year, of the famous old Bolaños silver mines, has been doing some road work preparatory to taking in pumping machinery for the unwatering of the extensive *antigua* workings. The unsettled conditions have delayed the company's plans. The Franco-British Syndicate, organized by French and English capitalists two years ago to build the Guadalajara-Chamela railroad in Jalisco, is waiting on the election of governor and members of the State legislature. Ernesto Madero, the present minister of finance, is authority for the statement that the new State government will guarantee the bonds of this railroad. It will open the Ayutla, Autlan, and other mining districts of Jalisco, and will be a valuable feeder for the National Railways. The Casados and El Favor Mining companies of the Hostotipaquillo district of Jalisco, have combined to build a wagon-road from the Casados and El Favor camps to La Quemada, on the Southern Pacific. The railroad terminus now is at Magdalena, 9 km. from La Quemada, but track is to be extended after the close of the rainy season. It is planned to place in service on the road electric trucks using the new Edison storage battery. E. A. Montgomery, of Los Angeles, has arranged for a year's extension of the option covering the Zapote mines in the Ameca district of Jalisco, and has ordered the sinking of a 2-compartment shaft to a depth of 500 ft. The shaft will prove the district at considerable depth, as the surface workings of the Zapote are much lower than those of surrounding mines. The option price is ₱100,000.

More than 1000 men are at work on the Conchos dam and reservoir of the Mexican Northern Power Co., a Canadian concern, in the State of Chihuahua, and it is announced that the big work will be finished by June, 1913. The power that will be generated will be transmitted to the Parral, Naica, Santa Barbara, Santa Eulalia, and other mining districts of Chihuahua, and it is expected to make a big difference in operating costs in those districts. During the revolution, the company's work was delayed by labor shortage. Water will be stored along the course of the Conchos river for a distance of 30 miles, the reservoir varying in width from 4 to 5 miles. It is estimated it will take ₱15,000,000 to carry out the company's plans.

Monthly shipments from the San Juan mine of the

San Juan Mining Co. in the Taviche district of Oaxaca average in value over ₱100,000. It is planned to sink the San Juan shaft, now down 700 ft., to a depth of at least 1500 and possibly 2000 ft., and a new hoisting plant is being put in. Plans for a 200-ton mill to treat the lower-grade ores have been made. The San Juan is the property that was returned to the San Juan Mining Co., an American concern, after much litigation, by a decision of the Supreme Court of Mexico, last year.

BUTTE, MONTANA

Heinze in the Coeur d'Alene.—Anaconda Production.—Butte-Ballaklava Resumes.—High Ore Ready.

F. Augustus Heinze has been on an extensive visit to the Coeur d'Alene district. During his stay there J. Parke Channing was in the district, and the two held conferences. While attending the annual meeting of the Stewart company, Mr. Heinze made arrangements for the doubling of the capacity of the Stewart mine. "We are now shipping 500 tons a day," said Mr. Heinze, "and just as soon as the arrangements are completed for the lease of the Federal company mill, we will increase the capacity to 1000 tons per day. Our new main working tunnel, which is now in 400 ft., will tap the Stewart orebodies about 2000 ft. from its portal at an added depth of 200 ft below our present lowest workings. To connect this tunnel with the railroad, we have obtained from the Bunker Hill & Sullivan company a lease of the necessary grounds over which to construct a branch line." There is a report that Mr. Heinze became interested in some other properties while in Idaho, but he denies the report. It is stated that he and his party secured an interest in the Morning mine. They visited the property and made a thorough inspection of one of the long tunnels. The Colorado mine of the Davis-Daly company is shipping and giving satisfactory returns. The ore blocked and in sight insures continuous shipments for an indefinite period.

The official figures of the Anaconda company production show that 22,500,000 lb. of copper was produced during August, as compared with 21,052,000 during July. During the last month the Washoe smelter produced 16,000,000 lb. and the Great Falls smelter 6,500,000, and in these figures is included the output of the North Butte and Tuolumne mines, which amounts to about 2,800,000 lb., the North Butte production being about 2,100,000 lb. The production of the East Butte smelter is given at about 1,100,000 lb. and in this is included the Butte-Alex Scott and some other small properties.

The Butte-Ballaklava company has commenced mining again after many months of idleness. The ground now being mined is claimed not to be covered by the injunction and is on the 1200 and 1400-ft. levels. On the east drift of the 1200-ft. level the superintendent says he has opened a vein on the foot-wall side showing between 18 and 24 in. of bornite and glance. Work is also progressing well on the 1400-ft. level. A shipment of two carloads was made a few days ago to the East Butte smelter, and it is intended for the present to ship about four cars a week. Mr. Newton has recommended to the directors that the shaft be lowered another 200 ft., which would make the depth 1600 ft., and he expects to receive word soon to go ahead with the sinking.

The shaft of the Ophir mine of the Butte Central Copper Co. will be down to a depth of 1000 ft. by the close of this week, and as soon as another 50 ft. is provided for a sump the work of cutting a station will be commenced. The Ophir is now shipping about a car of ore a day to the Washoe smelter, and the returns are averaging over $1800 per car. The work of cutting the station on the 2800-ft. level of the North Butte mine is progressing, and it is expected that it will be completed in about two weeks. Cross-cutting on the vein will then be started. The High Ore mine will be ready to resume operations under the compressed-air system of hoisting about the first of the month.

JOHANNESBURG, TRANSVAAL

Coal Shortage.—Electricity Popular.—Power Troubles.—Independent Stations Needed.

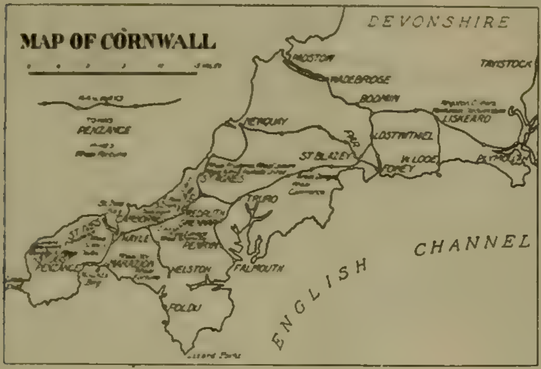
Complaints have been numerous of late that not only have the South African Railways been unable to supply the collieries with sufficient empty cars to keep them working, but, owing to the same cause, several of the gold mines have been on the point of closing for want of coal. During the last three years the railway has been frequently unable to meet its obligations in this respect, owing to lack of suitable cars, and it undertook to have a supply in readiness last April. Owing to the expectation that the Victoria Falls Power Co. would commence operations, this promise was not carried out. It was thought that the extensive use of electricity would materially reduce the coal traffic. Such has proved not to be the case, because the power-stations are all on the Rand, and coal from the collieries about a hundred miles distant has to be carried for their use. Then again, the power-stations use small coal previously unsalable and the collieries have experienced no trouble in disposing of the lump coal, so that, as a matter of fact, the power-stations coming into use have added to the coal traffic rather than diminished it. It is fortunate for the railways that all the collieries are in one association, thus enabling coal supplies to be diverted to the gold mines most in need of fuel. Otherwise, undoubtedly several would have been compelled to stop operations. In Natal likewise there has been a chronic scarcity of empty cars for a long time, at times throwing the collieries idle and the export trade out of joint. It is bad enough for the Rand gold mining industry to be crippled from such an unavoidable cause as scarcity of at least 50,000 negroes to complete their full complement of unskilled labor, without being threatened with a stoppage for want of coal. The fact is that the management of the South African Railways leaves much to be desired, but being Government-owned, a deaf ear is turned to all complaints and warnings. Industries are crippled by exorbitant railway rates, and, owing to the want of ordinary business foresight, the railways are poorly equipped and under-officered to such an extent that unless an early change for the better is made it will be impossible to avert a crisis. The change from steam to electricity at many of the Rand mines is not as complete as could be wished, owing to the inability of the power company to meet the demands. As a motive power, electricity is proving itself far more popular than steam, both for milling and hoisting at the mines. At several of the new producing mines where the only power planned for is electricity to be purchased and supplied by the Victoria Falls Power Co., the management is finding itself in a quandary, milling operations being restricted, and working costs unduly high in consequence. In fact, several mines originally intended to be worked exclusively by electricity have been compelled to provide themselves with steam-plants. The trouble is entirely due to preventable mechanical defects which the Power company officials are taking steps to remedy, but nevertheless the loss to some of the mines is severe. Apart from economy, this experience indicates that the Randfontein Estates and the East Rand Proprietary Mines have taken the correct step in erecting their own power stations.

It is hoped that the satisfactory results obtained at the Brakpan mine on starting its mill may give more confidence to the companies holding ground in the Far East Rand. The Brakpan company certainly displayed courage in sinking two shafts to such a depth in the face of their drill records, and it is to be hoped that equally good results will be shown on the adjoining State mines, where Barnato Bros. is sinking four large shafts to considerable depths without even testing the ground. There has never been any doubt as to the value of the outcropping Modderfontein properties, but the experience at Geduld to the north has not been reassuring, despite the excellent results shown by the first borings. The Geduld company has now obtained the necessary power to increase its nominal capital to £1,000,000. Recent exposures of veins on that property have been more encouraging, but on such a property as the Gedald it seems almost absolutely necessary that large scale operations be conducted if fair dividends on the huge nominal capital of the company are to be earned. It is in this part of the Rand known as the Far East that the most favorable conditions are expected as regards depth, but when water and stability of the foot wall are taken into consideration they leave much to be desired.

LONDON

Cornish Tin Mines.—Dolcoath.—Grenville.—Carn Brea & Tincroft. Wasteful Power-Stations.

The elasticity of the Dolcoath, the premier tin mine of Cornwall, is once more evidenced by the report for the half-year ended June 30 now issued. The underground work in connection with the new Williams shaft, and the substitution of Holman air-cushion or 'pneumatic' stamps for the battery of old Cornish stamps, have made it necessary to reduce the amount of ore mined and milled. To make up for the deficiency, it has been possible to raise ore of higher grade, and this fact, together with the advance in the price of tin, has had the result of bringing the total receipts to a substantially higher figure. The same policy was pursued during the second half of 1910, but not to the same extent. The tonnage raised and milled was 40,315, compared with 44,659 during the second half of 1910, and 47,279 during the first half of 1910. The concentrate sold was 852 tons, compared with 877 tons and 852 tons, a recovery of 47.38 lb. per ton compared with 44 lb. and 40.4 lb. The average price obtained per ton was £117 6s. 6d., compared with £97 15s. 2d. and £88 13s. 8d., and the receipts were £100,048, compared with $85,819 and £75,639. The profit, after payment of royalty, was £36,370, compared with £24,515 and £13,018. The working costs were not substantially different. The shareholders have received £34,000 as dividend, being at the rate of 10% for the half-year. The new battery of 8 air-cushion stamps is at work, and a further 4 are to be erected. The cage roads are completed at the Williams shaft, and the electrical hoisting engines and the electric pumps are being erected. It is expected that the plant will be ready for operation by the end of September. An interesting announcement is that the zinc-copper and copper-tin deposits in the Killas Shaft and Stray Park sections are being actively explored once more. Some years ago a flotation plant was erected for the treatment of these ores, but it was not worked regularly, owing to the lack of labor required for the development of the deposits. The directors are offering the remaining 10,000 shares *pro rata* among shareholders at par, £1; they have already received an offer for the whole or any part of the issue.



The Wheal Vor tin mine is situated in the Breage district of Cornwall, a few miles south of Hayle. It was reopened in 1906 by the Dolcoath group, but misfortune has dogged the steps of the enterprise. The electric pumps first supplied were of faulty construction, and the engines of those substituted, after having unwatered the mine to 864 ft. below adit, broke down. Enough exploratory work, however, was done in the interval to prove that there are several veins worth following. Owing to the difficulty of raising further funds, the mine has been idle for a year. The directors are now more hopeful of the prospects for another unwatering and reopening. They point to the fact that electric power can be obtained cheaply from the new central electric station at Hayle, which is supplying Dolcoath and South Crofty, and will shortly send current to Geevor at Pendeen. By taking advantage of this opportunity, cheap power could be obtained with little outlay of capital.

The present Grenville company was formed under the limited liability laws in July 1906. The mine is situated to the south of Camborne, and it had previously been worked for many years on the cost-book system. The ore yields a good quality concentrate fairly free from wolframite and iron and bringing a higher price at the tin ticketings than the produce of many of the neighboring mines. In writing of the company recently I mentioned that the new manager, Henry Battens, had introduced the wholesome practice of buying supplies in the open market instead of being dependent on directors or shareholders interested in the timber, machinery, and other trades. At the same time I recorded that he had made a profit of £4308 for the half-year ended December 31 last, so reducing the debit balance from £10,465 to £6157. The report for the first six months of 1911 shows that in spite of the continued water trouble the debit balance has been changed into a credit balance of £799. The amount of ore raised was 17,059 tons and the yield of concentrate was 266 tons, as compared with 21,047 tons and 298 tons during the second half of 1910. The extraction was 35 lb. per ton as compared with 32¾ lb. The income from sales was £30,293 as compared with £29,485, and the profit after paying royalty was £6956 as compared with £4308. The output was smaller than would have otherwise been the case because for at least half the time the water prevented access to the best stopes. Last autumn was unusually wet in Cornwall and the pumps at many mines were unequal to the extra duty imposed. Much time and money were spent by Mr. Battens in repairing the pumps, and afterward, when the water was lowered, in inspecting and strengthening the various workings. Mr. Battens writes hopefully of the future and describes several new finds of ore.

The report of the Carn Brea & Tincroft for the half-year shows that the yield per ton has fallen seriously, being only 22.29 lb. of tin concentrate per ton of ore stamped. Since the present company was formed in 1900, only once, namely, during the second half of 1903, has the figure sunk below 23 lb., and the average has been from 26 to 30 lb. The ore raised was 38,253 tons and the produce of tin concentrate 380 tons, as compared with 38,892 tons and 472 tons during the previous half-year. The best results were obtained during the first half of 1909, when 36,825 tons yielded 567 tons of concentrate. The income from the sale of tin concentrate was £39,038, figures practically identical with those of the two other periods quoted above, the price of tin being the compensating factor. During the past year the average price obtained for the concentrate was £102, as compared with £82 during the second half of 1910 and £69 during the first half of 1909. The sale of wolfram, copper, and arsenic ores and concentrates brought the total receipts to £41,057. The working cost was £41,492, figures slightly higher than the average of the last four years. To this has to be added £1501 for royalties, so that the result of the half-year's work is a loss of £1936. No allowance is made for depreciation. I have frequently referred to the current history of the company during the last year or so and have recorded the appointment of Edward S. King, late of West Australia, to the managership. In his report he foreshadows new methods of payment for underground contract work, improvements in the handling of ore, and the overhauling of the old dressing plant. He adds: "At present there are 8 hauling shafts and 5 pump shafts, and altogether 24 engines working under steam, and one engine on suction gas," a serious item in the standing charges.

General Mining News

ALASKA

The Tanana

On August 13, P. R. McGuire, in behalf of himself and others, recorded in the commissioner's court at Fairbanks 27 association claims, covering 4320 acres of supposed placer ground in the Beaver river district.

Ore showing $2.50 to the square foot was discovered in drilling on Wagner & Co.'s claim on Eva creek, about 1500 ft. above the present workings. The ore was found in the last five holes, and is believed to be an extension of the Wagner vein.

(Special Correspondence.)—The Tanana Quartz & Hydraulic M. Co. has let a contract to Nash & Littlewood for sinking a 100-ft. shaft on the vein discovered on the Texas claim of the Tony Goessman property, which is situated on the divide between Bedrock and Chatham creeks.

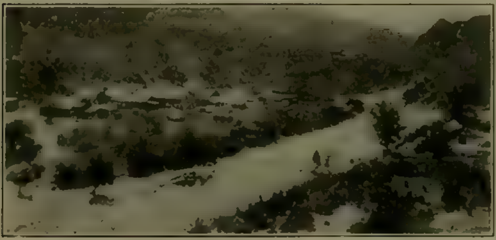
ARIZONA

Gila County

The output of the smelter of the Old Dominion Copper M. & S. Co. at Globe in August was 1,982,000 lb., bringing the total output for the first eight months of the year to 17,937,000 lb., against 18,330,000 lb. for the same period last year, and 24,750,000 lb. for the first eight months of 1909.

The directors of the Old Dominion Copper Co. of New Jersey, the operating company, have declared a quarterly dividend of $1 per share, payable October 5 to stockholders of record September 20. By this the Old Dominion Co. of Maine, the holding company, will receive $155,245, through its ownership of 155,245 of the 162,000 outstanding shares. The Maine company has declared a dividend of 50c., payable October 6 to stockholders of record September 20.

By a plan announced in Boston for consolidating the Arizona Commercial Copper Co. and the Superior & Boston Copper Co., the latter company will increase its authorized stock to 650,000 shares, par value $10, of which 200,000 shares will be offered in exchange for the $1,000,000 bonds of the Arizona Commercial company. The Boston & Superior company reserves the right to withdraw the plan unless it is accepted by 75% of the Arizona Commercial Copper Co. bondholders.



MINERAL CREEK, RAY DISTRICT.

Maricopa County

Cobalt has been discovered in the Saddleback district west of Phoenix, according to C. H. Howland, manager for the Palo Verde Copper Co. Samples assay 20.62% copper and 4½% cobalt per ton.

Pima County

The Imperial Copper Co., a subsidiary of the Development Company of America, has filed with the bankruptcy court of Arizona a schedule of its assets and liabilities. The assets amount to $2,435,121 and the liabilities to $3,333,146. Over-extensions and lack of coöperation between security-holders are given as the main causes for the failure.

Pinal County

The construction work for mine No. 2 of the Ray Con. Copper Co., including the steel head-frame, the electric hoist, and other equipment, has been completed. The surface equipment practically duplicates that of mine No. 1. The ore to be handled is richer than that from No. 1. On the 100-ft. level a new tipple has been put in, and the main drift has been connected with the Humboldt and M. & H. shaft. Extensive development work is being done on the 200-ft. level.

CALIFORNIA

Amador County

(Special Correspondence.)—At the Poundstone mine, a mile east of Sutter Creek, the drift from the bottom of the 300-ft. shaft is out about 500 ft., exposing a good body of ore. The vein has shown marked improvement recently. An electric pump will be ordered soon. The Poundstone adjoins the Bailol, formerly operated by a German syndicate. The South Eureka company is erecting several buildings at the Oneida, including change-house, machinery structures, etc. Electric wires have been strung and new lines of water pipe laid. The repairs to the Argonaut shaft have been completed, together with the work from the 1400 to the 2100-ft. level points. The two lower levels are being unwatered and active developments will shortly be resumed. After lying idle for about 20 years, the Sierra gravel mine, east of Sutter Creek has been reopened by Albert Martell, H. M. Hale, and J. M. Hendricksen. It is reported that the Defender mine will be acquired by new owners and placed in operation in October. The property has been idle since drowning of the bond-holder, Carl C. Forseen, in the Mokelumne river last winter. It is announced that the W. E. Downe coal mine, near Campo Seco, soon will be reopened. An engine and boiler have been received and the shaft will be unwatered at once. The deposit of coal is said to be of good grade, but has hitherto received little attention. It is planned to supply local mines with coal in place of the fuel oil now largely employed. Sedge Hartwick is manager.

Jackson, September 8.

Tuolumne County

The Uncle Sam mine, at Arastraville, has been unwatered for the purpose of a thorough examination for an Eastern company.

A large number of men has been added to the working force at the Dreisam and complete operations resumed. The winze to the north of the shaft on the 400-ft. level, in which the vein shows a width of 4 ft., is being sunk an additional 35 ft., which will make it 100 ft. deep. Drifts will then be started both ways. At present ore is being extracted from between the 400 and 300-ft. levels. In the near future developments will be pushed on the large vein recently discovered by cross-cutting on the 100-ft. level. J. E. Conde, the owner, is operating the property and is superintendent.

The vein which was first uncovered on the 1500-ft. level of the Black Oak is being driven both ways on the 1400-ft. level, where stoping is also in progress. At this depth there is 4 ft. of ore that will average $90 per ton. The lower-grade ore goes direct to the mill, while the best is being sent through a chute and stored in the level below. It is reported that the management later will build a modern mill and cyanide plant.

Tuolumne, September 10.

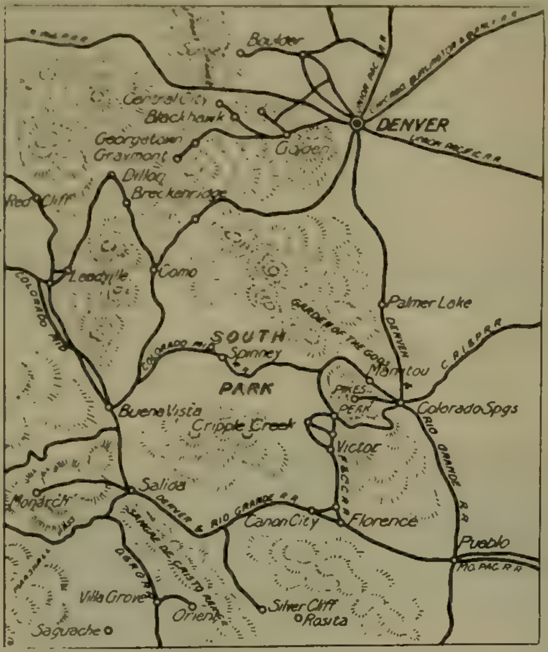
COLORADO

Clear Creek County

(Special Correspondence.)—A streak of silver-lead ore from 6 to 8 in. wide that carries 600 oz. of silver per ton has been uncovered on the Seven-Thirty vein by Joseph Wood, who is operating under lease. Eric Erickson has taken a lease on the West Griffith mine and is stoping on a body of lead-zinc ore that is from 2 to 3 ft. wide. The product is to be shipped to Idaho Springs for concentration at the Jackson mill. John Esgrig has taken a lease in the east drift of the Aetna vein at the Capital mine. Drifting is under way and a streak of 3-oz. gold ore is being followed that is from 8 to 10 in. wide. Work will be resumed in a few days on the Mint property, situated on Covode mountain. It has been decided to sink the shaft 400 ft., making the total depth 600 ft. The Temple Drill Co., holding a lease, will be allowed to develop all ground below the 200-ft. level, while the New System Mines Co. will operate in the upper workings. The 10-stamp mill will be brought into commission during the next two weeks.

Georgetown, September 8.

(Special Correspondence.) The Kitty Clyde mine last week shipped 18 tons of smelting ore that sold for $35 per ton in gold and silver. G. W. Ford is lessee. It is reported that a 12-in. streak of ore has been uncovered in the Dorit adit on Chicago creek that assays $400 per ton in gold and silver. It is stated that work will soon be resumed on the Specie Payment mine and that operations will be carried forward through the Two Brothers adit. The property has practically been in idleness for the last two years owing to litigation. A. M. Welles is manager.



PART OF COLORADO.

Idaho Springs, September 7.

Denver County

(Special Correspondence.) — According to allegations made in a lawsuit recently filed in Denver, the slag pile of the old Argo smelter in North Denver, which went out of business last fall, is worth about $500,000, on a basis of $5 per ton, while parts of it may be rich enough to bring the whole to a value of $1,000,000, at least it is so asserted. The trustees for the Boston & Colorado Smelting Co. contracted with H. C. Pringle and associates to let the latter sell the slag and pay the trustees 30c. per ton. Pringle arranged with H. C. Reno for the latter to sell the slag and pay the former and associates $1.10 per ton. The smelter is alleged to have agreed to pay Reno $1 per ton after deducting $2 treatment charges, freight, and the $1.10 for Pringle and associates. H. B. Little, plaintiff, alleges he was a partner of Reno.

Denver, September 9.

Gilpin County

(Special Correspondence.)—At the 1400-ft. level in the Topeka mine ore assaying $14,187 in gold per ton is reported to have been discovered. It is believed that at this depth the Topeka will come into the vein of uranium ore on which the Wood, Kirk, and German mines are operating. The ore is said to be the richest found in this section for several years.

Central City, September 8.

One hundred miners and prospectors recently organized the Tolland Mine Operators' Association of upper Gilpin county to revive the mining industry in that district. The meeting was held in Tolland. J. R. Braidwood is president. The meeting was promoted by a Denver newspaper.

'Wild West' pictures set in a real mining camp were recently staged at Tolland by the Selig film company. The 'canned drama' was of the popular romantic type.

Jefferson County

The ore-testing plant at the School of Mines at Golden cannot be completed, owing to the failure of the State to pay the educational appropriation.

Teller County

The Trilby mine, on Bull hill, shipped 29 cars of ore in August. A rich vein of sylvanite ore is reported to have been found at the 300-ft. level of the Commonwealth mine in Arequa gulch.

IDAHO

Idaho County

John and Edward F. Massam, of Spokane, have sold the controlling interest in a gold quartz property at Elk City to the Blanchet-Gamatot syndicate, of Paris, for $100,000. M. Snellus, chief mine manager for the syndicate, has taken charge of the developing of the property. Edward Massam still retains an interest.

Owyhee County

(Special Correspondence.)—The Rich Gulch M. Co., of the Silver City district, has ordered a 250-ton amalgamation and cyanide plant from the F. C. Richmond company. Grading for the plant has been almost completed. The company is driving an adit deeper on the vein, which is of gold-silver ore. A. F. Stevens is general manager for the company.

Silver City, September 9.

Shoshone County

The Gold Ridge M. & D. Co. has bought the Buckhorn mine in the Ten-Mile district. The company has ordered a 15-ton Chilean mill for delivery October 1. A. A. Hammer is secretary of the company. H. J. Rice is president and manager and is in personal charge of the work. The company is a Spokane corporation.

Official announcement that the output of the Stewart mine, in the Coeur d'Alene district, will be increased from 500 to 1000 tons per day was made by F. Augustus Heinze, president and controlling stockholder of the Stewart M. Co., on arriving in Spokane from an inspection of the property, on which he was accompanied by Maurice W. Bacon, Western manager, and E. H. Wilson, chief engineer. "We now are shipping about 500 tons per day," he said, "and as soon as the second mill, to be leased from the Federal M. & S. Co., is in operation, our output will be doubled. We have a call on the Tiger-Poorman mill at Burke, and we probably will utilize that plant. We find it costs less to lease this mill than to remodel an old plant."

MICHIGAN

Houghton County

The directors of the Copper Range Con. Co. have declared a dividend of 75c. per share, making the payments so far for 1911, $3.50 per share. Since 1905 a total of $31.50 per share has been paid in dividends. The payments last year in the aggregate were $4.

Drill-hole No. 15 of the Mayflower M. Co. has passed through two copper-bearing veins, one being remarkably rich. The hole is down 1040 ft. No. 7 drill-hole of the Contact-Elm River company is down 250 ft. The vein was found at a depth of 185 ft. Work on the 460-ft. level of the Houghton Copper Co. has been stopped, and development has been resumed below the 475-ft. level.

MISSOURI

Jasper County

The Jack Possum M. Co. has been incorporated at

The Odell-Daley Material Co., capitalized at $5000, paid up, has been organized at Joplin to handle mine tailing, using it for railroad ballast, material for concrete manufacture, etc. Incorporators are O. M. Odell of Joplin, and J. A. Daly, F. M. Daly, and S. A. Wright, all of Nevada. At the Missouri Standard mine a rich body of ore averaging between 64 and 65% zinc has been found. A mill will be started. This ore, near the Four Corners, is as rich as any in the district, according to report.

MONTANA

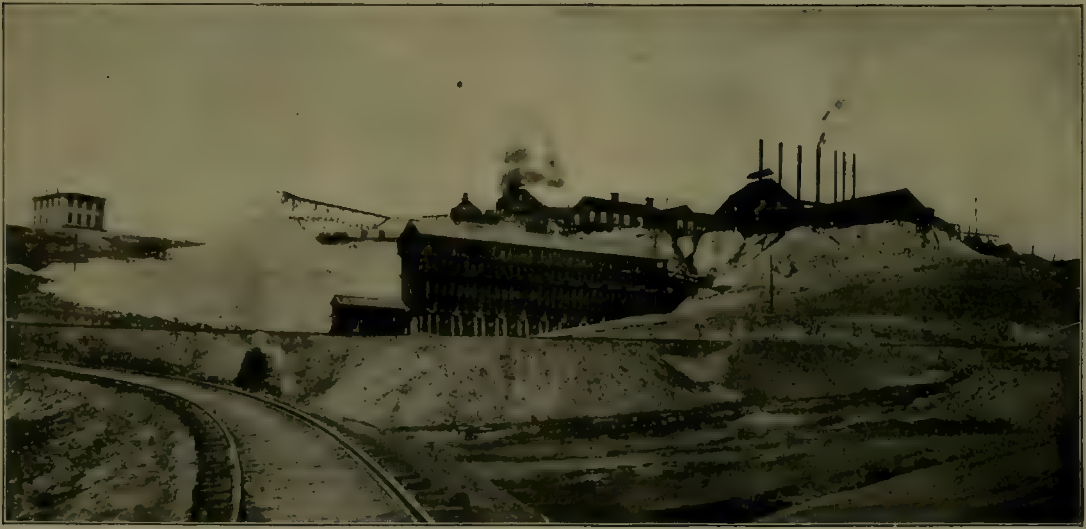
LINCOLN COUNTY

(Special Correspondence.)—Through the piercing for the first time of what has proved to be a false bedrock in the placer workings on Libby creek, a layer of rich gold-bearing gravel has been uncovered. A dollar and a half in gold has been taken from each pan of gravel from the bottom of the hole, and there is other ground which has the appearance of being similar. With the steam drilling-machine brought in here recently by J. Y. Ownbey and G. F. Hinton to prospect upon ground owned by William Criderman and John H. Town, a hole was put down to a clay formation which heretofore has been considered the bedrock on all the Libby creek placers. Then, by way of experiment, the drill was sent on down, and it was found that the clay was only 3 ft. thick, underneath which was a 3-ft. layer of gravel rich in gold. The hole is 48 ft. deep. There is an area of about 2000 acres of placer ground on Libby creek. Among the owners of placer ground near the Criderman-Town claims are the Libby Placer M. Co., headed by P. J. Brophy of Butte; the Comet Placer M. Co., also controlled by Butte men; George Chews of Spokane, and the Howard brothers of Libby. Throughout all of it, sufficient gold is found above the clay 'bedrock' to pay for working it on a large scale, but much greater possibilities are now opened up. The ground adjoining the discovery is taken up, and there is no chance for new locations.

Libby, September 12.

SILVERBOW COUNTY

It is reported that in the near future the Tuolumne Copper Co. will ship its ore direct to the Washoe smelter in Anaconda, as the Butte, Anaconda & Pacific railroad soon will be connected with the mine. The change will eliminate hauling the ore by teams and will save about 60c. per ton. The new plant of the Tuolumne company is to be completed within two months. The company has found an orebody 18 ft. wide on the north vein at the 1600-ft. level. The ore assays from 10 to 12% copper with some silver.



MINES AT BUTTE, MONTANA.

Ore shipped from the Ophir mine of the Butte Central Copper Co. so far has averaged $1800 per carload, according to report. Electrically driven air-compressors are now used at the mine, an electric pump is planned, and within a few months an electric hoist may be used. The new mill is to be ready in December.

NEVADA

ELKO COUNTY

It is reported that the Western Asset Co., German branch of the Rothchilds, is planning to erect an electric smelter at Contact, and build a railroad line from the camp to Valley Pass, on the Southern Pacific. Valley Pass is near Cobre. The company is to receive a 25% interest in all claims in the Contact district in return for the smelter and road. It is to put in a dam on the Little Salmon river for a hydro-electric plant to run the mines and smelter.

ESMERALDA COUNTY

A Philadelphia syndicate, including J. A. Steinmetz, J. A. Vincent, and J. S. Janney, is negotiating to acquire the control of the Vernal M. Co. in the Diamondfield district, with the intention of starting development immediately.

(Special Correspondence.)—H. A. Darms, of Napa, California, who with relatives owns extensive coal deposits at Coaldale, intends forming a company to develop the property. Some development work has been under way for six months, and his mine is said to be the first one in the State to operate its engine on coal from the mine. Fair quality coal was found at the 200-ft. level, and good coal at the 250-ft. level. The vein is 7 ft. wide, and there are four other veins east of the one being developed. R. W. Cattermole, chief engineer of the Tonopah & Goldfield railroad, is said to be interested. Adjoining claims are being developed by a syndicate, of which J. V. Ravenauck, Russion consul at Pittsburg, Pa., is a member. While the freight on Wyoming coal shipped to Tonopah is $9 per ton, it is reported the freight from Coaldale is about $1.50. The operating costs are about the same.

Tonopah, September 14.

HUMBOLDT COUNTY

Newspaper reports state that a vein discovered in a raise in the old Borland mine of the Rye Patch Con. property has ore which yields 500 oz. silver per ton and $125 from the screenings. The property is being operated by the Conlin brothers, formerly of Sierra City, Cal., and in Joplin, Clark Marshall being one of the chief stockholders. The property, in 'Possum Holler', Chitwood, is said to produce nearly 30 tons of blende per week.

the old days was one of the bonanza properties of the county.

According to C. W. Culver, of the Culver D'Armond lease at Awakening, the Critchfield discovery at that camp shows an 18 in. vein which pans over 50c. per pound.

LANDER COUNTY

(Special Correspondence.)—Maricopa Mines Co. has intersected a new orebody at a point 910 ft. from the portal of the True Blue adit. It is reported to be 7 ft. wide and to assay 20 oz. in silver and gold per ton. Silver predominates. East and west drifts are under way, and a raise has been completed from the adit to the surface. It is expected to have the mill in operation before winter sets in. The tramway from the mines to the mill-site has been completed. The Maricopa holdings lie in New York canyon, a short distance from the town of Austin. A shipment of 500 sacks of high-grade ore was recently made by the Austin Manhattan company from the Jack Pot mine to smelters, forming the second consignment of the month. A large quantity of milling ore has been extracted. It is understood that the dry-concentrating plant is effecting a recovery of over 70%. Francis L. Judd and California associates have taken the Yankee Blade mine under lease and bond. The 830-ft. shaft has passed through the Ford & Johnson and Confidence veins, with a cross-cut from the 300-ft. level intersecting the Yankee Blade vein. A 25-hp. hoist is on the ground and will be placed at the vertical Yankee Blade shaft, which will be unwatered.

Austin, August 24.

LYON COUNTY

The Nevada Douglas Copper Co. has entered into a coöperative agreement with the Western Gypsum Co. whereby the former will ship from its deposits at Yerington to the latter's mill at Reno. Walter C. Orem is president of the Nevada Douglas company and John L. Howard of San Francisco is president of the Western company. Shipments will be started in a few weeks.

J. M. Collier in the Sunrise district has discovered a vein of ore said to assay $200 gold per ton from the foot-wall and $600 per ton from the hanging wall. The vein is only 6 in. wide at the surface. J. G. Kaufman, of Yerington, bought the Empire-Nevada Copper M. & S. Co. property at a sheriff sale.

NYE COUNTY

On the northeast cross-cut on the 800-ft. level of the Rescue-Eula mine, a few days ago there was found a rich vein of quartz, which in streaks assays from $40 to $60 per ton, according to press reports. The cross-cut after penetrating 6 ft. had not reached the hanging wall.

The Tonopah Extension produced during August $56,000 worth of bullion, or 4384 tons of ore, an average of over 141 tons per day, according to unofficial reports.

(Special Correspondence.)—Directors of the Tonopah-Belmont company, at a meeting in Philadelphia last week, ordered the payment of the fourth dividend for this year, of 25c. per share. On the 1,500,000 shares outstanding the amount distributed will be $375,000, and will bring the total dividends this year to $1,350,000, and the total in dividends paid by the company to $2,093,000. Owing to a reserve fund held in the treasury the construction of the new Belmont mill in Tonopah will not affect the payment of dividends.

Tonopah, September 5.

WHITE PINE COUNTY

There are persistent rumors that the Ely Calumet Copper Co. of Ely, which has been idle since 1907, will resume operating in the near future. It is said that Al Myers and G. L. Rickard will have charge of the reopening of the property.

(Special Correspondence.)—The Giroux shaft has been again sealed, since when it was opened fire was discovered smoldering on the tenth level. It is doubtful whether the cause of the fire will ever be known, since the only man who probably knew was among those killed.

Ely, September 9.

NEW MEXICO

DONA ANA COUNTY

The Memphis Copper Co., operating the old Memphis mine in the Organ camp, is said to have found an 8 ft. vein of $60 ore at the 175 ft. level. N. J. Dailey is manager for the company.

SOCORRO COUNTY

(Special Correspondence.)—Shipping ore assaying $200 per ton is being sacked at the Little Charlie group of the Mogollon Gold & Copper Co. It is reported that a 90 day working lease has been let on a portion of the old Cooney mine.

Rapid progress is being made in constructing the new power plant of the Ernestine M. Co. The oil storage tanks have been received at the mines. Delivery of engines and other equipment will be made in September. During the past two weeks 1050 tons of ore was treated, with a concentrate product of 4 tons. Bullion for the second 10-day period of August amounted to 5100 oz. The slight curtailment in capacity of the plant is due to shortage of water.

Additional leaching capacity is being installed in the mill of the Deadwood mines. The gold and silver bullion product since last reported amounts to 5000 oz. Last week's ore treatment was 400 tons, with 20 sacks concentrate.

Good headway is being made in excavation and foundations for the new power plant of the Socorro mines, which will be erected near the reduction works. The mill is reported as now treating about 165 tons of ore per day.

A three-year bond and lease has been granted on the Iron group property, and it is said that extensive development will be started.

Mogollon, September 1.

OKLAHOMA

OTTAWA COUNTY

In the Miami, Oklahoma, camp an entirely new ore formation has been found in a drill-hole at a depth of from 170 to 204 ft., the ore being of much higher grade than the average at Miami. In the extreme north end of the camp development is being pushed toward the 290-ft. level, where a body of zincblende has been defined in a dozen or so drill-holes put down.

UTAH

SUMMIT COUNTY

Through an alleged mistake in signals, seven men in the lowest of the three decks of the cage at the Daly West mine at Park City were plunged into the sump, where the water was 17 ft. deep. Two men were drowned. J. E. Bamberger, president of the company, states the men disobeyed orders and should have been on the top deck. The hoist was in charge of an extra man, who, it is asserted, had operated the engine in a satisfactory way several times before the accident.

CANADA

BRITISH COLUMBIA

The British Columbia Copper Co. in July produced 854,122 lb. of copper, 11,777 oz. of silver, and 2430 oz. of gold. The July production of copper last year was 574,172 lb. The June 1911 production was 816,676 lb. of copper, 11,742 oz. of silver, and 2428 oz. of gold.

The Granby Con. M. S. & P. Co. in July produced 1,228,646 lb. of copper, against 1,671,000 lb. for July 1910. Its silver production was 21,038 oz., also considerably less than its production in July 1910, which was 29,205 oz. Its gold production was 2990 oz., against 3484 oz. in July 1910.

Lyman Carter, of Spokane, who is president and manager of the Blue bird mines in the South Rossland district, is planning extensive development of the property. A spur track is to be run to the mine and three shifts of men will be placed at work. Shipments of silver-lead ore are expected to be made to the smelter, beginning September. The Curlew and the Mayflower are producing high-grade ore from what is believed to be extensions of the same vein.

The Board of Conciliation and Arbitration as yet has not succeeded in ending the strike of miners in British Columbia. While the Granby company is still closed down, the British Columbia Copper Co. announces that it will not cease operations for the time being at least, and that it has ordered 5000 additional tons of Connellsville coke from Pennsylvania.

ONTARIO

The directors' report of the Apex Porcupine Mines, Ltd., issued this week, shows that 1,300,009 shares have been issued, of which 1,000,000 were in payment for the company. There remains in the treasury 699,331 shares. From the sale of stock $56,259 was received, which with $42 interest on bank deposits, brings receipts to July 31 to $56,701. For general expenses and development, $13,461 was spent, leaving a balance of $43,240. The report of P. Kirkegaard, engineer for the company, is included with the statement to stockholders.

The Temiskaming & Hudson Bay M. Co. paid a dividend of 300% August 31, state press reports, making the fourth paid this year and the third in the last three months. The dividend was the 32nd paid by the company since its formation in 1905, and on the 7761 shares issued the payments have amounted to 18,400% on the stock. The company has no definite periods for paying dividends.

The Swastika Central company, owning 18 claims in the Swastika district, will experiment with a shot-drill on the Green claim, at Pike lake, adjoining the Swastika mine.

A. G. Kirby is planning a mill for South Porcupine, but construction will not be determined for several months. It is to be a custom mill. Ten drills have been started on the McIntyre claim, which is equipped with a 12-drill compressor.

A site has been selected for the proposed $250,000 mill at the McIntyre, state reports from Porcupine. It is said the machinery will be in place before winter. The structure will be of reinforced concrete. Albert Freeman, president of the company, states that the mill will be prepared to crush ore milling $5 per ton, although he believes that for several years the value of the ore will average over $10.

Newspaper despatches assert that the International Nickel Co., headed by Ambrose Monell, operating the Dome mine, and interested in the Dome Extension, and reported to be the owner of the Jowsey-Wood claims in Carscallen, has bought the Porcupine Imperial company's property. Harry I. Taylor of New York is president of the latter company.

The Wettlaufer Lorrain Silver Mines, Ltd., with properties in Cobalt, has declared its regular quarterly dividend, No. 3, of 2½%, with the customary 2½% bonus, payable October 20 on stock of record October 10.

YUKON

The Yukon Gold Co. paid a quarterly dividend of 2%, or 10c. per share, on September 12.

MEXICO

BAJA CALIFORNIA

The Compagnie du Boleo in July produced 1,973,680 lb. of copper, against 2,315,040 lb. in June. The production for the first seven months of 1911 is 16,678,353 lb. of copper, against a production of 17,025,609 lb. for the same period in 1910.

CHIHUAHUA

Improvements at the Sierra Plata mine will increase the output from 90 tons per day to 300 tons in the near future.

It is reported that the smelter at Santa Rosalia will resume operations within two months. Bernard MacDonald will be in charge, and it is believed William Thompson, superintendent of the Veta Colorada M. & S. Co., will be superintendent.

As the result of one week's work at the Veta Colorada mill recently 26 bars of bullion, valued at $28,000, was shipped to the Stallforth bank at Parral. The capacity of the mill soon will be increased to 600 tons per day. C. F. Spaulding is manager.

(Special Correspondence.)—The report for July of the Rio Plata M. Co. shows a net return on shipments of $81,889. The stamp-mill crushed 1769 tons of dry ore which yielded 73,169 oz. of silver and 23.4 tons of concentrate. The cyanide plant treated 1999 tons of tailing containing 56,573 oz. of silver. The total value of silver recovered was $73,343, and operating expenses were about $12,500, leaving an operating profit of $24,842. There was expended on mine development $442.

Chihuahua, September 3.

(Special Correspondence.)—Owing to a temporary cessation of milling, operations at La Republica for July were as follows:

Tons milled	567
Production	₱32,861.01
Operating charges	₱35,846.15
Capital expenditure	₱ 2,622.60

The rainy season having brought an abnormal increase of water-flow in the mine, extraction of ore has had to cease pending completion of measures to protect the workings, and further production will be deferred accordingly.

Chihuahua, September 1.

SONORA

The Greene-Cananea Copper Co. has decided to operate the Puerticitos mine again, but it is probable that shipments will not be heavy. It is thought that while the decision indicates abandoning a retrenchment policy, the company still will keep its output between 3,500,000 and 4,000,000 lb. per month. Commencing with June, there has been no extraordinary construction expense to charge against cost of operating. At a cost of $4,000,000 the company has remodeled its plant thoroughly. The Sierra de Cobre mine, bought last year from Phelps, Dodge & Co., is said to have the low-cost record of the Greene mines. Ore is treated by direct smelting.

It is reported that James Box, Jr., son of Capt. Michael James Box, the first American traveler and explorer of Mexico, and an old-time ranger of Texas, is planning to purchase mines, mentioned in his father's memoirs, situated 12 miles east of Bavori. The property is said to have high-grade silver ore and to have been worked by the Spaniards.

GERMANY

The United States exported 91,771 tons of the 101,149 tons of copper required to satisfy the demand for the metal in the January-July period. Germany imported in all 160,077 tons, and exported 4928 tons of copper, according to figures compiled by Aaron Hirsch & Son.

PERU

Cerro de Pasco M. Co., according to apparently reliable reports, will commence to pay dividends in the near future. In the year ended June 30 there was shipped to the United States 48,600,926 lb. of copper to be refined and sold. In the year previous only 32,248,859 lb. was shipped, although that figure is over 5,000,000 lb. above that for the 1908-1909 twelvemonth. The bulk of the copper, if not all, is to be handled at the Baltimore refinery of the A. S. & R. Co., which has a contract for refining and selling the product of the Cerro de Pasco company.

PHILIPPINE ISLANDS

BENGUET

The Headwaters mill at Baguio is handling from 60 to 70 tons per day. Recent rains provide an abundance of water. It is stated that for ten months of the year there is no shortage in this source of power. At other times gas-engines are used. An extra engine has been ordered from the United States to insure running throughout the year. F. L. Cole, of Cole & Hanlon, is consulting engineer of the plant.

The stamps crush the ore in a cyanide solution through an 8-mesh screen, the pulp passing to a double cone classifier and a Callow thickener. The oversize passes to a Hardinge tube-mill. All ore passing a 100-mesh screen goes to a conical collector, from which charges are pumped to Pachuca tanks.

Personal

Professional men are invited to send news of their engagements and travels. Such news is interesting to friends.

W. H. Emmons is at Creede, Colorado.

John B. Farish is expected in San Francisco.

Courtenay De Kalb is to be in San Francisco.

T. Lane Carter is in Mexico examining mines.

R. S. Rainsford was in San Francisco Tuesday.

Gardner F. Williams is at the Fairmont in San Francisco.

C. Colcock Jones has gone to Nevada to examine properties.

F. Lynwood Garrison is examining coal lands in West Virginia.

G. L. Sheldon will return to Sonora about the first of October.

J. E. Adams, of Hawthorne, Nevada, was in San Francisco this week.

Stephen Rickard has been visiting San Francisco and other West Coast cities.

R. B. Brinsmade is superintendent at the Flojonales mines, Hidalgo, Mexico.

James M. Hall, whose headquarters are now in Chicago, has gone to Porcupine, temporarily.

John E. Rothwell, who is visiting Western metallurgical plants, was in San Francisco this week.

Stuart H. Ingram has been appointed manager for the Galenista G. M. Co., operating in Chihuahua, Mexico.

Leonard Sivyer will return to Los Angeles about September 20 from an extensive trip of exploration in San Diego county, and in Lower California, Mexico.

H. Kenyon Burch, mechanical engineer for the Miami Copper Co., will spend the next sixty days on the Pacific Coast, recuperating from an attack of peritonitis.

S. E. Bretherton will go to Denver about October 1, but hopes to return to San Francisco in time for the meeting of the American Institute of Mining Engineers.

T. C. Crawford, president of the United Gold M. & M. Co., sailed for London, September 13. He expects to return to San Francisco about the first of February.

Juan Felix Brandes, whose headquarters are now in the Newhall building, San Francisco, is leaving shortly for an extensive trip through Chile, Peru, and the Argentine.

Chester B. Allen, superintendent at the Tarantula mine of the United Gold M. & M. Co., has been appointed general manager for this company in California, with headquarters for the present at Chinese Camp, Tuolumne county.

Recent Publications

Commission on Conservation, Canada. Lands, Fisheries and Game, Minerals. Pp. 519, ill., index. Ottawa, 1911. Approximately half of this elaborate compendium is devoted to the minerals and the problems of the mineral industry of Canada. The mining laws and regulations are summarized, as are the statistics of production and of mine accidents. There is also a most interesting general chapter upon the conservation of the mineral resources. The spirit which pervades the report may be indicated by the following quotation:

"In considering the conservation of mineral resources it is of the utmost importance to observe the following facts: (1) There will be no mineral industry without profits; that is to say, no mining company will mine or extract these resources in such a manner as to entail continuous loss to itself in order to conserve such resources for the future. (2) The present generation has the power and the right to use *efficiently* so much of these resources as it needs. The past has proved that the needs increase with the extension of our industries, and more rapidly than the population. (3) The nation's needs will not be curtailed. The people will take what they require. Conservation of our mineral resources may be accomplished by investigation, education, and legislation. Investigation should be carried on to determine the nature and extent of each of our important resources; the rate at which each resource is being utilized; the nature and extent of the waste in mining, extraction, and use of each mineral product; how this waste can be prevented; to discover and develop substitutes which may take the place of products of importance, the supply of which is limited; to discover methods for utilizing by-products or other materials for which, under existing conditions there is no commercial demand, and if individuals and corporations are such that wasteful methods are used in order to make large financial profits, regardless of the rights of the future, such action should be restrained by legislation."

No attempt was made to estimate reserves of any of the metallic minerals, though the commission makes it clear that an increasing production is to be expected. Waste in the mining and milling of gold, silver, and lead is considered unimportant. In copper and nickel mining it is held to be large though mainly unavoidable. A recommendation that all slag, tailing, and other products containing metal but not marketable be stored, and that running such materials into streams be stopped. An approximate estimate of the coal reserves of the Dominion is made and many interesting and valuable data are brought together regarding the other non-metallic minerals of which Canada is so important a producer. The tone of the whole report is conservative but helpful.

The mining of phosphate rock for fertilizer showed increased activity in 1910, with the greatest production in the history of the industry, according to F. B. Van Horn of the U. S. Geological Survey. The output was 2,654,988 long tons, against 2,330,152 in 1909. Prices, however, were lower, the value of the 1910 output being $4.11 per ton, against $4.62 for 1909. While the tonnage in 1910 increased 13.9%, the value of the year's output increased less than 2%. Nearly half of the phosphate rock produced in 1910 was exported. There are at present five producing phosphate fields in the United States. In the order of quantity of production they are: (1) Florida, (2) Tennessee, (3) South Carolina, (4) Arkansas, (5) Idaho, Wyoming, and Utah. By far the largest of these fields is the Idaho-Wyoming-Utah field, where enormous deposits of high-grade phosphate rock, recently discovered, are available for mining. The field next in available unmined rock is probably Tennessee, where large areas are underlain by deposits of high-grade rock. Florida has a large reserve tonnage, but at the present rapid rate of mining it will not be many years before the rock will be exhausted. South Carolina has been mining phosphate rock since 1868, and the production has steadily declined since 1889, with the exception of two or three years, when a slight increase in production was noted. Arkansas has never been much of a factor, and, so far as known, the deposits are not of great extent.

The mine production of gold, silver, copper, and zinc in Tennessee in 1910, according to H. D. McCaskey, of the U. S. Geological Survey, was valued at $2,289,731, a decrease of $305,619 from the corresponding value for 1909. The gold production was 150.59 fine ounces, valued at $3113; the silver, 81,239 fine ounces, valued at $43,869; the copper, 16,837,727 lb., valued at $2,138,391; and the zinc, figured as spelter, 1,932,555 lb., valued at $104,358. When compared with the corresponding figures for 1909 these figures show decreases of $1005 in the production of gold and of 2,369,079 lb. and $358,494 in copper; but increases of 23,602 fine ounces and $13,898 in silver and of 740,394 lb. and $39,982 in zinc. A total of 578,434 short tons of ore was mined in 1910, of which 552,796 tons were copper ore and 25,638 tons were zinc ore. In 1909, 576,680 tons of copper ore and 34,334 tons of zinc ore were mined.

Commercial Paragraphs

The Crocker-Wheeler Co., of Ampere, New Jersey, announces the opening of a San Francisco office, room 400, First National Bank Building, in charge of John S. Baker, district manager.

Wm. H. Armstrong, for many years mill superintendent for the Dos Estrellas Mining Co. at El Oro, Mexico, has joined the sales force of the Mexico Mine & Smelter Supply Co., at Mexico City.

F. F. Lacks, Pacific Coast manager of the Orenstein-Arthur Koppel Co., is in Europe on an extended trip. During his absence D. W. Dodge and A. A. Prausnitz will assume the management for the company.

C. F. Braun & Co., Inc., has succeeded the corporation known as Braun, Williams & Russell. The new firm will continue to represent the Alberger Pump Co. Its address is the same—503 Market street, San Francisco, California.

Benjamin T. Delafield, who formerly represented the Lunkenheimer company for a number of years in the St. Louis and Kansas City territory, has become connected with the Best Mfg. Co., of Pittsburgh, Pa. He will make his headquarters in Kansas City.

The Geo. E. Dow Pumping Engine Co. has opened a display-room at 179 First street, San Francisco, where there are now on exhibition a great number of all styles and sizes of pumps for mining, irrigation, and water-supply. A full line of compressors is also represented.

The Gandy Belting Co., of Baltimore, sole manufacturer of the Gandy belt in the United States, has adopted a novel idea for distinguishing the Gandy belt from the other stitched cotton-duck belts. Commencing September 1, 1911, one edge of the Gandy belting will be painted green, while the rest of the belt will remain red as before, and it will continue to bear the brand "THE GANDY BELT" and their trade-mark, a coil of belt and a bale of cotton laid across it, printed upon the belt at intervals throughout the entire length of the roll.

The Griffin Co., San Francisco, agents for the Robins Conveying Belt Co., has recently secured a contract from the Melones Mining Co., Calaveras county, Cal., for a system of belt conveyors transporting and distributing ore direct from crushers to storage-bins. The equipment comprises three 16-in. Robins Belt-Conveyors, 12, 50, and 166-ft. centres, respectively, and one distributing tripper. The ore discharged from the crushers is carried directly to the bins by the main conveyor and is distributed the entire length of the bins by a long conveyor running at right angles to the main one, distribution being obtained by the Robins automatically propelled self-reversing tripper.

Catalogues Received

New York Engineering Co., New York. 'The Empire Hand Prospecting Drill.' 36 pages. Illustrated. 6 by 9½ inches.

The Excelsior Drill & Mfg. Co., Denver, Colorado. 'The Excelsior Airometer.' 8 pages. Illustrated. 6 by 9 inches.

Electric Weighing Co., New York. 'The Electric Weigher for Belt Conveyors.' 4 pages. Illustrated. 6 by 9 inches.

Joshua Hendy Iron Works, San Francisco. Bulletin No. 119, 'Stamp Mills.' Illustrated. 32 pages. 6¾ by 10¼ inches.

The Jeffrey Mfg. Co., Columbus, Ohio. Bulletin No. 41. 'Single Roll Coal Crusher.' 8 pages. Illustrated. 6 by 9 inches.

Atlas Engine Works, Indianapolis. Bulletin No. 201. 'Atlas Crude-Oil Engines' (Diesel Type). 36 pages. Illustrated. 8 by 10½ inches.

Allis-Chalmers Co., Milwaukee, Wis. Bulletin No. 1512 (Reprint), 'Compound Corliss Engines.' 12 pages. Illustrated. 8 by 10½ inches.

THOUSAND-FOOT steamships are puzzling the harbor authorities of New York to provide docks for their accommodation. Before long we may be hearing of the struggles of the building commission to provide landing-places for airships on thousand-foot sky-scrapers.

NEW YORK leads in arranging for sectional meetings of the American Institute of Mining Engineers. The program for September 22 was the completion of the organization of the section and the reading of a notable paper by Mr. C. P. Perin on the iron and steel industry of India.

A SENATE bill provides that no higher postal rates shall be charged within the United States than are imposed upon matter mailed to foreign countries; in other words, that residents of the United States may have the benefit of the international parcels-post service. Perhaps the express companies are beginning to realize that increased facilities produce increased business, and that there is business enough for all, without any necessity for special privilege.

MANKIND is naturally hopeful, and the general depression which has long been widespread in business circles is so extraordinary as to call for volumes of comment from all sides. When such a habit of mind is persisted in there is danger of its becoming chronic, and it is unfortunate that the ghost of past over-speculation still lingers to hamper with its haunting memory the healthy growth of new business. Men learn by their mistakes, and the lesson acquired in 1907 should be an aid to business recovery.

THE American Mining Congress has postponed its forthcoming session until October 24 to 28 in order to secure the presence of the President, Mr. Taft, of Walter L. Fisher, and J. A. Holmes, and to permit the attendance of a large Alaskan delegation. The topics for consideration will be the prevention of mining accidents, workmen's compensation, the prevention of waste of natural resources, problems of coal mining, the Alaska question, and the relation of the mining industry to the public lands. These are fundamental and their interested discussion by a large body of representative men must naturally bear fruit in progress attained.

PLAGUE of the pneumonic variety, which last year ravaged eastern Siberia and northern China, was, as many of our readers know, derived from tarabagans, Asiatic marmots similar to our prairie-dogs, which are much hunted in Siberia for their skins. The sick animals communicated the disease to their slayers, who carried it to the villages, whence it spread, and was apparently about to sweep over north China when it was checked by prompt preventive measures. A commission, which has recently been studying the tarabagan in its native haunts, reports that there is no danger of a recrudescence of the plague this winter. It is said that the cackling of geese saved Rome; sick marmots seriously threatened the safety of the Chinese Empire.

NOTABLE economy in the use of timber will result from the action of the lumber associations in putting into practice the plan suggested by the Department of Agriculture of selling lumber in odd lengths. Now a stick too short to make a 16-foot length is cut to 14 feet, though builders often could use odd lengths to better advantage; studding, for example, is commonly 9 feet long. The new departure is a reasonable one.

VISIT of the Secretary of the Interior to Alaska has already been beneficial in producing a better feeling. Judging from private letters and local newspaper comment, Mr. Fisher made an excellent impression on Alaska, as the Territory did on him. Complaint emanates from Ketchikan because he was there the guest of the Alaska Packers Association. It was not to be expected that everyone would be satisfied, but fear that Mr. Fisher might be too favorable to 'exploiting corporations' is a new note.

ONTARIO goldfields continue to attract attention, and the new district, at West Shining Tree, has become the objective point of many prospectors. Many areas in Ontario are of much promise and may prove in the end to be of much value, but it should not be forgotten that the actual production of gold in Ontario is small as yet, and that the excitement created by a new discovery is not a reliable index of its true worth. The great value of some of the mines has already been demonstrated. Conservative statements are all that are desirable, and will in the end produce the soundest growth and development.

THE pacific power of capital is seen in the situation in Europe, where the great banking houses have spoken with authority regarding the Moroccan dispute. Primitive peoples may go to war whenever they hear the Red Gods calling, there being little to suffer injury except the anatomy of the combatants, but a modern civilization has too many interwoven threads of international interest to permit of disturbance without the gravest need. The boys may scuffle in the barn; the older people comport themselves differently in the drawing room. Arbitration treaties do not exhibit the growth of friendly feeling alone, rather they exhibit a realization that nations cannot afford to go to war under present circumstances.

PROSPECTING would be made easy if only a brief set of rules could be prepared giving the prospector infallible directions where to look for valuable deposits of ore. How to procure such a set, and how to be sure they are infallible, is another matter. Many prospectors work out for themselves something of the sort, with varying degrees of faith in its infallibility. Sometimes the conclusions reached are based upon inaccurate observation and faulty deduction, with the result that the final state is worse than the first. But when the problem is attacked by scientific methods generalizations of much value may be formulated. The frequent association of ore deposits with vulcanism is now well established and some years since Mr. T. A. Rickard pointed out that this in certain areas was of Tertiary age. On another page Mr. C. R. Keyes points out the importance of the form of vulcanism, and emphasizes the frequency of association of ore deposits with laccoliths. When we limit the inquiry to an area in which similar mineral associations occur, a petrographic province, other factors have a recognized index value; thus Mr. F. L. Ransome detected the association between alunite and gold at Goldfield, and many other interesting and useful instances of mineral association have been noted and used. The geologist, who knows that such generalizations have only been derived from the careful study of a great mass of conflicting evidence, is able to use them with safety and to advantage; the prospector who sees in them only a short cut to success, frequently employs them in a way that leads to but little of success or satisfaction. Such guides are only of general value; just as it is unsafe to make the assertion that the well brought up son of highly respected parents will necessarily prove a useful and successful man. When geologic guides to prospecting are over-emphasized the resulting reaction is likely to produce the depressed state of mind of the Cornish prospector who said "wheer she is, theer she be; wheer she bain't, theer be I."

PERUVIAN petroleum is lighter in grade, and hence more valuable for refining than that of California. Last year the Standard Oil Company imported 125,000 barrels of Peruvian oil, and it is interesting to note that the tank steamer bringing it north carried California crude in return. The principal developed oilfields of Peru are near Paita, in the northern part. The Lobitos Oilfields Ltd., according to *Peru To-day*, had 92 producing wells on December 31 last. The wells are about 1300 feet deep, and had initial outputs as high as 250 barrels. A second deeper sand is known and the ground is being tested to depths of 3000 feet. In southern Peru oil is also being developed in the province of Huancane, where the Titicaca Oil Company is active. The total output of the country in 1910 is estimated at 1,400,000 barrels, and there is every probability that production will increase here as elsewhere in South America.

San Francisco Meeting of the Institute

Plans for entertaining members of the American Institute of Mining Engineers on the occasion of their visit to California are rapidly assuming final form. At Los Angeles a strong local committee has been formed and the Eastern members will be entertained at dinner, probably on the evening of their arrival. Friday they will be given a trip to the beaches, and Saturday an automobile ride around the city and to Pasadena. Owing to the visit of the President to San Francisco October 14, and the exercises incident to beginning construction of the Panama Pacific Exposition, the plans previously announced by the San Francisco committee have had to be changed. The general excursion to the oilfields has been abandoned and in its place members desiring to visit Bakersfield will be given opportunity to do so, October 8 and 9, between sessions at Los Angeles and San Francisco. Meetings will be held in the latter city Tuesday afternoon, October 10, and Wednesday and Thursday forenoons. Evening sessions will be arranged if desired. Wednesday afternoon the party will be taken by special train to Palo Alto, where they will be met by resident members and shown through Stanford University. A similar excursion to Berkeley is also to be arranged, as well as trips to various metallurgical and manufacturing plants around the Bay, at times most convenient to small parties. Friday the engineers will be taken to Natoma to see the great dredges and rock-crushing plant. They will be given a luncheon at the club-house of the Natomas Consolidated of California, and will have every opportunity to see the operation of the dredges of the Natomas and Ashburton companies. Messrs. Newton Cleaveland, Corey C. Brayton, and Robert E. Cranston constitute the local committee. Saturday will be spent at San Francisco, where the Exposition officials have arranged an elaborate program and where in the evening there will be a carnival showing the city at its best. Sunday the excursion to the Bohemian Grove will be conducted as previously announced. Incidentally, these changes will reduce the cost per individual for California members who desire to take part in the excursions. Owing to the necessary absence of Mr. M. L. Requa, financial arrangements have been taken over by the general committee, and members desiring to contribute to the guarantee fund should send checks to the chairman, Mr. W. C. Ralston. An excellent meeting is assured, but it is hoped that as many as possible of the three hundred or more members resident in California will arrange to be present.

Smelter Fume

Smelter fume has been for some years past a critical problem in the metallurgy of the metals which chiefly occur as sulphides, of which copper, lead, and zinc are the most important. Smelters, like many other industrial plants, have always been considered undesirable neighbors because of the odors emanating from them, though when compared with tanneries, glue factories, stockyards, fertilizer works, and many other useful and necessary forms of industry, their offense seems almost negligible. The solid particles in the fume, gradually settling in the neighborhood of the stack, have also been sources of complaint. Dust of any sort is objectionable, and it has also been urged that the chemical effect of the dust settling from smelter fume is deleterious to the vegetation upon which it may settle, and to livestock that may browse upon this vegetation. It is unquestionable that injured vegetation and dead livestock have been found in the vicinity of smelters, but that the damage was the direct result of smelter fume can rarely be definitely proved.

The solid particles commonly present in smelter fume are of two kinds, fine particles of ore and flux which are carried off by the force of the draught, obviously no more objectionable than the ordinary dust of a country road, and fine solid particles which have been produced in the smelting operation itself. The most important of these are condensed sublimates of some of the volatile metals, notably oxide of arsenic, and H_2SO_4. The latter is produced in roasting and smelting both by the catalytic action which certain oxides, principally of iron and silica, exert on SO_2, and by the decomposition of various sulphates by heat. The SO_3 thus formed takes up moisture as soon as it has cooled sufficiently, forming a fog of sulphuric acid. Except when smelting a charge high in sulphur, the amount thus formed is undoubtedly small, and it is unquestionable that the damage produced has often been greatly exaggerated. Where any considerable amount of arsenic is present in the ore it will largely escape as fume and may poison livestock grazing near the smelter. There has been much controversy over the subject of smelter fume, and only a few points seem to be clearly established as yet. One is that the damage complained of has often been greatly exaggerated and in many cases can be proved to be due to causes other than smelter fume. The second is that damage has been done in some instances. The third is that it is commercially feasible to remove solid particles from fume before allowing it to escape. The Cottrell electrical process of precipitating solid matter had given good results at the Balaklala when that smelter was closed for a variety of reasons, and it has also been found possible to neutralize the sulphuric acid formed and then to remove all the solid by filtering through bags, in much the same method as that employed in the production of sublimed pigments of zinc and lead. Part of the cost of this work is defrayed by the increased recovery from the solids; the remainder may be regarded as an excise tax upon the privilege of carrying on smelting operations in agricultural districts. That a smelting industry should be compelled to carry this burden when the smelting operations antedate the agriculture would seem unreasonable, but legal privilege does not always coincide with justice and equity. The third cause of complaint is the most difficult to deal with. In roasting and smelting operations large quantities of SO_2 are discharged into the air; practically all of the sulphur driven off in roasting and all the sulphur of the smelting charge which is not drawn off in the form of matte escaping in this way. That SO_2 will injure vegetation is known to everyone who has had occasion to disinfect a sickroom containing growing plants; that the gas must be of a certain degree of concentration to produce injury is capable of equally simple demonstration. Theoretically the gases escaping from the smelter stack quickly mix with the outer air and are so diluted as to become harmless. Practically, it appears difficult to secure complete mixing of escaping gases with the great mass of the atmosphere, and they frequently travel to a considerable distance in nearly their original state, as the muddy water of a small tributary is often distinguishable in the clearer water of a large river for long distances below the point of inflow. Where the percentage of sulphur on the charge is low, this is no great matter, as the undiluted gases are not concentrated enough to produce injury, and smelting works have, for example, long operated undisturbed among the fertile farms of New Jersey. But where the sulphur content is high, as in pyrite smelting, the degree of concentration becomes dangerous, and the injurious effects of the gas may be increased by a moist climate, which tends to heighten the effect of SO_2, or by the topography, which may produce atmospheric currents that carry the escaping fume, undiluted, into contact with nearby vegetation.

Blowing air into the base of the stack by means of fans has been tried, but that the power cost is a disadvantage of this method is obvious. Converting the SO_2 into SO_3, which may be made into sulphuric acid, is done at the plant of the Tennessee Copper Company, and the objectionable gas is thus made a source of profit. But this can not form a universal solution of the problem; the initial outlay required is too great for small companies, and if all smelting plants engaged in the manufacture of acid the market would be inundated. It is also necessary that the fume shall have a high concentration in SO_2 to allow its economical conversion into acid. The problem is accentuated by the statutes of some States, which provide that the escaping fume must have a sulphur content so low as to be procurable only at a prohibitive cost. As described on a following page, Mr. Stewart W. Young has attacked the problem boldly by proposing the reduction of the SO_2 to sulphur by hydrocarbons, using calcium sulphide as the intermediary. The suggestion is a novel one, and the results of trial upon a working scale will be of much interest. Evidently one problem will be to bring the fume thoroughly into contact with the calcium sulphide without interfering seriously with the draft. In this connection it may be noted that in the early stages of the Gayley dry-blast process it was suggested that the blast be passed over calcium chloride, to which it would give up its moisture, the chloride to be regenerated by passing the gases of combustion over it. The mechanical difficulties of this method were found insuperable, though recent reports from Germany are to the effect that the method is being successfully practised there. In many other cases where a reversible reaction has been made the basis of a continuous process it has been found that after a number of reversals the reaction becomes slow and incomplete. The question of cost is the vital one, and the sulphur produced can scarcely be counted on as an asset. The cost data of experiments upon a working scale will be the criteria of success, and meanwhile we assume the prerogative of extending the thanks of the profession to Mr. Young for his efforts toward the solution of an urgent metallurgical problem.

Vanadium Deposits in the Caballo Mountains, New Mexico

By Carl A. Allen

Among practical mining men and many mining engineers there was long an inclination to consider vanadium and uranium as rare metals, whose consideration and study should be left to the research chemist and rare-metal enthusiast. This was also true of tungsten, but as the deposits of wolframite, in Boulder county, Colorado, and elsewhere, have now for some time been engaging the activities of metal miners, vanadium is also beginning to be regarded as a metal to be sought and its deposits studied like those of gold, silver, or copper.

The principal use of vanadium is in the manufacture of steel. It gives to steel toughness and the ability to withstand repeated shocks. The parts of automobiles that must stand the severest strains, especially jarring strains, are made from vanadium steel, as is drill steel for rock-drills.

So far as I am aware, only two States can boast of workable deposits of vanadium; Colorado and New Mexico. In Colorado the ore is principally carnotite and is found in stratified rocks in the region from Placerville west to the Utah line. In New Mexico the deposits of vanadinite or vanadate of lead, which this article describes, were really discovered in 1909, although the veins had been worked for lead for a number of years. The Caballos mountains, in which they are found, are about half way between Albuquerque and El Paso, in Sierra county. They run parallel to and are about six miles east of the Rio Grande river. Their length is about thirty miles, and near the northern end is the site of Elephant Butte dam, the largest project of the United States Reclamation Service. The highest elevation is about 10,000 ft., or from 5000 to 6000 ft. above the bed of the river. Near the mines, Palomas pass divides the range into North and South Caballos. The nearest station is Cutter twelve miles nearly due east on the Atchison, Topeka & Santa Fé railroad.

Geologically, the region is old, and, to the casual observer, unattractive. Leaving the railroad for the mountains, the first six or eight miles of the country is flat and barren, the road now and then passing over nearly obliterated sheets of black lava. Then low, rough foothills are reached that have been formed by the tilting of sedimentary beds of limestone, shale, and quartzite. These continue to the foot of the main range, and were, no doubt, tilted when the range was formed. The range itself is more like a long, rough hogback, and is composed of sedimentary beds of limestone lying on its eastern slope, and on the western side granite, gneisses, and schists. F. C. Schrader[1] calls the age of the limestone Carboniferous and makes note of a large bed of Cambrian quartzite below it, and also of a large fault scarp on the western side. The beds are, no doubt, of Paleozoic age, as fossils of that age are abundant. Beds of gray limestone are interspersed with thin strata of shale and calcareous slate. These beds I would class as Silurian, while the red strata geologically next above, and which form a line of hills just east of the veins, are, no doubt, the Carboniferous 'Red Beds' mentioned by Schrader.

For at least six miles, parallel fissures that cut these sedimentaries can be found, and a number of them have been prospected for lead. While the fissures are strong and well defined, the lead in the form of galena is of low grade and in scattered places in the veins, perhaps being confined to a contact between a bed of limestone and shale.

In the exploration of these fissures for lead, the Southwestern Lead & Coal Co. has been active. Many feet of work was done on the Napoleon and Rosa Lee veins, and considerable low-grade galena found on the latter. The company built a small concentrator for its treatment, and to add to its holdings purchased the Swan and Dewey veins. As these two are now the ones being actively worked for vanadium, their history may be interesting. The Dewey was located by R. Widner and his father. The White Swan was located by non-resident prospectors, and when they allowed their rights to lapse, Widner located the claims early the morning of April 1, 1906, only to find that R. T. Ward had been there at midnight and located ahead of him, giving it the name White Swan. Ward, however, agreed to allow Widner a half interest for doing the location work, and later traded to him his remaining interest for a Jersey cow. In the fall of 1907 Widner sold both claims to the Southwestern Lead & Coal Co. for $3000. They were considered valuable at that time only as lead prospects. The Dewey had practically no work on it, the Swan a short adit and a shallow shaft. In the adit was a streak of galena and a 6-in. streak of pure vanadinite. This was called lead carbonate, although the elder Widner was not satisfied about it and spent much time studying the long, brown, hexagonal crystals which separated so beautifully in his pan. The transfer to the lead company was made shortly before that company ceased operations, and very little more work was done. The two veins lie parallel, about 700 ft. apart, and are one and one-half miles north of the old lead mine, where the concentrator is situated. After the discovery of the value of the vanadium content of the veins, A. B. Bement, of Terre Haute, Indiana, one of the stockholders of the lead company, organized the Vanadium Mines Co. This company took over all the property of the lead company and has been actively at work developing these two claims and working out the treatment of the ore.

NEW SWAN HEAD-FRAME.

DEWEY HEAD-FRAME AND ORE-BINS.

The third and only other vein of importance so far opened up is the Red Top, one end of which is owned by R. Widner and the other end by J. H. Hardin. It was quite extensively prospected for lead, and has one shaft over a hundred feet deep. The vein lies south of the Swan and Dewey veins, about ¼ of a mile, being about half way between them and the lead zone.

---

[1] 'Ore Deposits of New Mexico,' U. S. Geol. Surv. Prof. Paper 68, p. 284.

As before mentioned, these three veins belong to a large number of parallel fissures in massive limestones and slates. The three have galena in common with the others, but also have vanadinite, or vanadate of lead, which the others do not have. The ore occurs in shoots from 2 to 20 ft. wide, and of undetermined length. In the Dewey vein the vanadinite occurs in coarse crystals, sometimes almost black. The hanging wall is well defined and is usually followed by a streak of almost pure crystals in solid radiating masses or disintegrated as crystalline sand, the color being dark brown to black. Away from this streak the ore occurs as fine crystals in a fine black dust, probably pure manganese oxide in a very porous gangue. This gangue varies from barite and calcite to a slightly altered limestone. In the latter case the black oxide of manganese fills the seams and cracks and when panned yields beautiful yellow-brown crystals of vanadinite. In the main working shaft at 75 ft. a natural cave was found, 3 ft. wide, 30 ft. long, and 12 ft. high. There is very little galena in this vein.

CONCENTRATOR, WITH CABALLOS MOUNTAINS IN BACKGROUND.

The White Swan vein is the most developed and presents the most interesting study. It has a main shaft with drifts on the vein at 80 and 140 ft. From the first level a winze has been sunk toward the second, and a raise brought to the surface. Considerable stoping has been done. The vein is from 2 to 20 ft. wide, and the vein filling is a porous, friable calcite or altered limestone, with varying amounts of barite and fluorspar. The porosity ranges from vug-holes the size of a marble to caves 5 and 10 ft. long. The ore is of two classes; the most common is vanadinite in minute hair-like crystals, much finer than those in the Dewey, and usually as little rosettes lining the cavities in the vein filling. The crystals, although perfect in form, are exceedingly delicate and slender. They are of a yellowish brown color, and with a white background or base of calcite form specimens of exquisite beauty. Where these crystals occur, the solid portion of the gangue is impregnated with the same material, making the fine and coarse of the broken rock nearly uniform in grade. The other ore is both a molybdate and vanadate of lead, impregnating the altered and silicified lime. This ore is non-crystalline, and although containing many vugs and cavities, is hard and much more difficult to break than the other ore. The manganese dust that is found in the Dewey vein is found in many places in the Swan vein. Also at nearly every place in the Swan vein can be found a streak, 12 to 18 inches in width, having galena and small amounts of copper carbonates. This streak may be in the vein or lying on either wall. Often there will be a gradual change from the soft porous gangue containing the vanadinite to the firm silicified limestone bearing the coarse cubes of galena.

The genesis of the deposits presents an interesting field for study. The scarcity of the mineral in workable deposits and its occurrence here in only three of a large number of parallel fissures is sufficient to arouse the curiosity of the economic geologist. From the data that can be gathered at this stage of the development of the mines, it appears that there have been two distinct earth movements at widely separated periods of time. The first was, no doubt, when the Caballos mountains were formed and caused the large fault on the western face and the original fissuring on the eastern slope. The second disturbance was apparently productive of very little structural change, but from the cooling magma of the intruding rock hot solutions emanated and, following the line of least resistance, circulated in the old fissures, and by processes of replacement and fresh deposition, took away part of the galena ores and left vanadinite. That there has been replacement there is no doubt, little cavities showing perfectly by their shape that they once held crystals of galena, are now lined with crystals of vanadinite. Also the gentle gradation from vanadinite in its soft porous gangue to galena in a harder, less altered gangue is further evidence of replacement. That this replacement was effected by circulating meteoric or surface waters is improbable. First, because the magnitude of the deposits is great and the process of deposition has been carried far into the walls beyond where any signs of former galena deposits can be noted. Second, because surface waters frequently contain hydrochloric or sulphuric acid, both of which are solvents for lead vanadate. Third, the veins at the present time are entirely without water, and its presence at any time in any quantity, such as to cause a secondary enrichment, would have left appreciable amounts of the green oxide of vanadium, of which there is practically none.

East of the shaft on the 80-ft. level of the Swan mine, occurs a very sharply defined fault plane, cutting the vein at nearly right angles and dipping to the east 45°. To the west of the fault the ore-shoot is 15 ft. in width and shows extensive mineralization. On passing through it, a larger part of this is cut squarely off and the minerals appear as seams of very rich ore along a relatively narrow body of average grade ore and in little cracks often running far into the lime. These conditions indicate the existence of this fault plane when the waters that formed the vanadium shoots were circulating. Its slickensides of clay formed a barrier to the solutions, with the resulting larger mineralization on the one side.

The shoots dip to the east, and Mr. Bement directed the early development of the property with the idea of their following the dip of the strata and being confined to one or more certain beds of limestone. Working on this assumption, and carefully watching the ground as it was being opened, he kept the workings always in ore, with the result that there is a remarkably small amount of dead work in either mine. That there is some change in the mineralization as the vein passes into various beds of limestone, there is no doubt, but personally I do not believe that the shoot will be found to have the same dip as the strata. It seems to be more nearly vertical and approaching the dip of the fault plane. Mr. Bement located this fault plane on the surface of the Swan claim, and I noted several evidently of the same series between the Swan and Dewey claims. If these faults continue with depth, they will probably influence the outline, if not actually determine the dip of the shoots.

The Red Top vein shows the same features as the Dewey and Swan. At either end of the vein the combination of molybdate and vanadate is seen to be the dominating type of ore. This vein can be traced for a greater distance than the others, and the shear-planes parallel to the main fissure indicate considerable fracturing. No compact orebodies of magnitude, like those of the Swan and Dewey, have as yet been found. In the main shaft driving has been done on irregular bunches of yellow massive ore, while to the side of it is seen manganese oxide containing vanadinite. In this is a cave some 10 ft. wide, 10 ft. deep, and 30 ft. long.

What igneous rocks are associated with the different earth movements can only be determined by careful field study and petrographic examination. North of the mines, there are extensive flows of lava. East of the concentrator can be seen the remnants of a flow lying on the 'Red Beds,' and east in the vicinity of Ward's ranch there are numerous dikes cutting through the Cretaceous strata, some of which can be traced for long distances.

Statements as to the average grade of the ore might at this time be misleading, due to the relatively limited amount of development. The Vanadium Mines Co. has expected the mines to average 1% ore. Pure vanadinite contains 10.8% metallic vanadium, and it follows that the grade of the ore can be regulated a great deal in the mining or by sorting. Of the massive ore free from crystals, the combination of vanadate and molybdate runs from ¾ to 2%, which is better than where the molybdate is absent. When ready for steel, as ferro-vanadium, the metallic vanadium is worth at the present time $4 or $5 per pound. At this price ¼% ore has a gross value of $20 to $25 per ton, and with a modern mill and proper treatment of concentrate should yield a good profit. There is very little difference in assays from the three veins, and all have large quantities of ¼ to ½% material, and although an attempt may be made to keep the grade up to 1% at first, the lower-grade material will, no doubt, be eventually treated.

The treatment of the ore is first by concentration. The old lead concentrator is used for concentrating the ore in a small way and as a testing plant to determine the most efficient equipment for a modern mill nearer the mines. The mill is inadequate for permanent duty, principally because of the lack of fall in the original site. The ore must be ground to at least 20 mesh, to liberate the minerals, and this means the slender friable crystals are reduced to fine. This and the presence of the barite are the most difficult features in the concentration; a modern mill, however, should effect a good saving. The pure mineral contains 65% lead. Its specific gravity is the same as galena, but, unlike that mineral, there is no tendency for the fine ore to float.

Water is a very serious question in this part of New Mexico, and the present supply for this mill is obtained from drilled wells at the power-plant, four miles east. The water is pumped this distance through a 4-in. spiral-riveted pipe, and although the profile of the line is rough (the maximum head being 350 ft.), no great difficulty has been met.

To obtain the vanadium from the concentrate two processes are required: (1) obtaining the vanadium oxide, (2) converting the oxide into ferro-vanadium, in which form it is used by the steel companies. The first is the most difficult and expensive process. The Vanadium Mines Co. erected a plant at Cutter to leach the vanadium from their concentrate with sulphuric acid. The lead is left as a residue of lead sulphate and the liquor containing the vanadium is evaporated to dryness and the residue calcined to vanadium oxide. One difficulty is to secure a thorough leaching. The acid has a tendency to form a coating of lead sulphate on the outside of the grains of mineral, which protects the inside from further action. Experiments have been conducted along the line of smelting with an acid flux, the vanadium to be then leached from the slag with water. This has been done in Germany and may be found to be more efficient than the acid treatment.

This company is the pioneer with this class of ore, and, like all pioneers, must by experience and increasing knowledge of the peculiar conditions, work out the method that, from a commercial standpoint, will be the most profitable. Others that come after will profit by its experience.

ALABAMA'S gold production in 1910 was 1622.16 fine ounces, valued at $33,533, and that of silver 268 fine ounces valued at $145, according to H. D. McCaskey of the U. S. Geological Survey. These figures show an increase in value of gold output for Alabama of $4294 and an increase in silver output of $35 in value. The silver production is entirely from recovery of this metal in refining the gold. The production of gold and silver in Alabama in 1910 was reported from three deep mines and three gold placers. The total placer gold was valued at $357 in 1910, as against $69 in 1909. The deep mine production was from 9763 short tons of ore with an average recoverable value per ton in gold and silver of $3.41. In 1909 the ore production was 9886 short tons, but the recoverable value per ton was only $2.96.

THE SLOPE of the surface at any point is one factor determining the amount of water absorbed by the ground. The direction and amount of slope also determine the form of the water table; that is, of the upper limit of saturation. Except where the surface is flat, the water table is generally not parallel with the surface; it is almost invariably farthest from the surface on the summits of hills and mountains and nearest to it in valleys and along the coast, reaching the surface in swamps and along rivers, lakes, and beaches. The surface of the water table is always in motion, its higher portions flowing toward the lowest outlets along rivers or the sea. This direction of flow explains why fresh water is usually found when a well is dug in a sandy beach.—'Water-Supply Paper 223,' U. S. Geological Survey.

Unprofitable Copper Mines

By J. R. Finlay

[*]Several of the Lake Superior companies have mined copper at a loss, even during the high prices of the last five years. This fact was ascertained early in the investigation, and unless their records showed some signs of progressive improvement, no particular attention was paid to these concerns.

Franklin Conglomerate. The Franklin Junior mine has been working a conglomerate lode between Hancock and Calumet. During the past five years it produced 15,258,000 lb. of copper at an average of 16.7c. per pound. The output declined from 4,571,000 lb. in 1906 to 966,000 lb. in 1910. This record is such that the mine can be classed as absolutely unprofitable and I appraise it at zero.

Atlantic Mining Co. makes the following report: "The Atlantic mine caved in May 26, 1906, and the work done since has been entirely of an exploratory nature except that the stamp-mill has been doing some custom work, and this work shows no profit. It was done to keep the mill in condition to use if anything of value was found on ore lands. Explorations are now all stopped and the machinery is being dismantled."

This mine was formerly profitable, but suddenly caved in, as above described, because the openings had become too extensive. This property has recently been absorbed by the Copper Range Consolidated. The consideration was an issue of 10,000 shares of stock of the latter company, equal to 2½% of its capital. As the Copper Range Consolidated owns the Baltic and Tri-Mountain mines and half the Champion mine, together with the Copper Range railroad, it is plain that the valuation to be put on the Atlantic is 2½% of the total valuation of the Copper Range Consolidated. As this includes appraisement of the railroad company, I cannot state exactly what the amount should be, but based upon the valuation I have put upon the above-mentioned mines, it should apparently be about $350,000. This valuation covers 962 acres of mineral land and a mine which is stated to be as good at the bottom as it ever was, but needs to be reopened from the surface.

The Winona Copper Co. produced during 1906 278,182 lb. of copper at a cost of $1.05 per pound; 219,332 lb. of copper at a cost of 32c. per pound in 1907; and in 1908, 39,310 lb. at a cost of more than $5 per pound. It has been developed by two shafts: No. 3, 1272 ft. deep, and No. 4, 1460 ft. deep. The rock mined during the last year of production, 1907, produced 12.6 lb. of copper per ton. This record shows the mine to be absolutely unprofitable.

The King Philip Copper Co. has spent during the past five years $909,840; is developed by two shafts, one 1124 ft. deep and the other 1324 ft. deep. The latter showed ground like that opened in the Winona mine. This mine evidently has no value, the only hope being a remote one of finding better rock. The large amount of exploration done on the Winona and King Philip would ordinarily be considered a sufficient demonstration of the possibilities.

The Ash Bed Mining Co. attempted a little mining in 1906 and 1907, producing 1600 lb. of copper in 1907 at a total cost for the period under review of more than $8 per pound. In 1907 mining operations were discontinued and have not since been renewed.

The Tamarack Mining Co., which formerly paid large dividends, has become distinctly unprofitable during the period under review. It is still producing considerable copper, having produced 58,314,000 lb. during the last five years. Its average cost has been 15.2c. per pound. In 1906 the cost was 15.29c.; in 1907, 16.98c.; in 1908, 15.53c.; in 1909, 14.1c.; in 1910, 14.53c. Undoubtedly the management hopes to reduce the cost and make some profit, but I am not willing to appraise hopes when contradicted by the figures on such scale as this. I, therefore, value the mine at zero.

The La Salle Copper Co. produced 791,000 tons of copper during 1909 and 1910, at a total cost of 45½c. per pound. This property has a large acreage on the Kearsarge, Osceola, and Calumet conglomerate lodes. The southern end has still no promise. No. 1 and 2 shafts are down 2000 ft. and 1400 ft., respectively; about 17,000 ft. of driving has been done, and out of 181,075 tons hoisted, 64,598 tons were treated as ore, yielding 10.8 lb. of copper per ton. If this record demonstrates anything, it demonstrates that the property is hopelessly unprofitable, and I appraise it at zero.

The Gratiot Copper Co. produced in 1910 29,869 tons of rock which were stamped, yielding 283,615 lb., this being a recovery of 9.5 lb. per ton. Operations were suspended April 1, 1911, apparently with very good reason, and I appraise this property at zero.

The Centennial Copper Mining Co. occupies 640 acres of land at the south end of the Kearsarge lode. It adjoins the South Kearsarge and Wolverine mines on the west, and it would be strange if none of the ore worked by those companies crossed the line. However, the record of this company shows no promise. During the last five years 10,980,000 lb. of copper has been produced at a cost of 18.4c. per pound, the total loss in five years being about $290,000. While admitting that this mine may become profitable, this event depends entirely on the extent to which the Wolverine orebody may cross over upon its ground. It is not by any means impossible that it may never do this, as some of the ore-shoots take a course almost due north, in which case the Wolverine orebody might continue in a direction parallel to the Centennial boundary. I, therefore, appraise the value of this mine at zero.

The Victoria Copper Mining Co. has produced in the last five years 5,270,000 lb. of copper at a cost of 19c. per pound; the average yield is 10.9 lb. per ton. This record shows the mine to be hopelessly unprofitable.

The Mass Consolidated Mining Co. has produced during the past five years 10,988,000 lb. of copper at an average cost of 18.3c. per pound. This mine has been securing about the same results for the last twelve years and has called assessments for the amount of $2,100,000. Its record shows it to be hopelessly unprofitable, and I appraise it at zero.

The Michigan Copper Co. has produced during the five years under review 10,561,000 lb. of copper at an average cost of 20.7c. per pound. Mining operations were suspended in 1910, having continued for some twelve years. They cannot be considered as anything more than an experiment on a grand scale, which proved the property to be hopelessly unprofitable. This company undertook to reopen the old Minnesota mine, which was closed down some thirty or forty years ago after paying more than $1,700,000 in dividends. The mine, at that time, was given up as worked out. It was supposed that improvements in methods and facilities would make the veins profitable again. This belief has cost the stockholders of the Michigan more than $2,000,000.

I give the above details of these various properties to show at a glance the conclusive character of the evidence in regard to nearly all of them. To attempt to place a valuation upon properties which have no better record than most of those mentioned would be only a joke. In most cases these operations are simply costly experiments more or less completed, undertaken in the hope of developing a profitable mine. When the experiments are carried along beyond the period when the demonstration is thorough, the continuance is a psychological phenomenon.

NON-PRODUCING COPPER COMPANIES

In the data submitted is a long list of copper mining companies which have not produced during the five years I have reviewed. Some of them have produced in the past, but have closed down permanently; others have produced nothing at all. I have sought for some logical means for placing an acreage value on the undeveloped or demonstrated lands situated upon the copper-bearing rocks, but without success. It may be taken for granted that the long list of unprofitable enterprises mentioned above were undertaken upon the best showings of copper that could be found outside of the tracts owned by the profitable mines.

---

[*] Abstract from a report to the Board of State Tax Commissioners of Michigan.

It seems ridiculous to place a valuation upon lands which have no showing at all when costly operations upon lands that have considerable showings of copper have not proved those showings to have any value, but, on the contrary, in most cases have proved them *not* to have any value. The fact is that the copper district has been pretty thoroughly explored. The only surely valuable deposits discovered in the last thirty years were those on the Baltic lode. The discovery of these mines, together with a theory that the mining business could be put on an improved basis through the installation of larger plants designed to handle a larger tonnage, caused a boom in the district which lasted pretty continuously from 1898 to 1907. The hopes entertained during this period inspired the expenditures of vast sums of money for explorations, the result of which has been meagre. It is probable that the people of the district have not fully recovered from the speculative mania which lasted so long. Many owners of mineral rights undoubtedly hope to dispose of them for fancy prices. This is largely because in the past promoters have been able to float mining companies and sell their shares to the public. They have actually preferred in many cases to pay owners large sums in cash for their lands rather than to issue stock for them. This kind of a market has no reference whatever to the intrinsic value of the properties. I take the ground that the State of Michigan does not wish to recognize extrinsic valuations created by promoters whose business is not to produce copper but to gauge the public appetite for speculation.

The St. Mary's Mineral Land Co. owns all the stock of the St. Mary's Canal Co. and half the stock of the Champion Copper Co. The St. Mary's Canal Co. owns about 86,000 acres of land in fee simple and 14,000 acres of land the surface of which has been sold but the mineral rights reserved. Such companies are rarely popular. It is very easy to create in the minds of the people the suspicion that such companies are holding large tracts of land for high prices and thereby impeding proper development, and, in a word, living on the unearned increment. In the case of the St. Mary's Mineral Land Co. this suspicion is hardly justified by the facts. A careful inspection of the record of this concern shows that during the past four years it has earned nothing applicable to dividends except a portion of its dividends from the Champion Copper Co., which of course is appraised separately. Its total receipts from sources other than the Champion Copper Co. dividends are as follows:

Land sales	$227,398.50
For wood and timber	27,253.64
Notes	66,000.00
Ground rent	9,330.39
Interest and sundries	59,785.49
Total	$389,768.02

But its expenditures in the attempt to open up new mines have been very large. Following are the assessments paid during these years on shares in copper companies:

King Philip company	$672,714.00
Winona company	6,736.00
Hancock Consolidated	160,000.00
Ojibway	4,000.00
Houghton Copper Co.	55,555.00
Challenge company	138,000.00
Office	57,792.66
Taxes	86,921.80
Franklin District	2,220.00
	$1,176,939.46

This statement proves that the company has lost $787,171.44, excluding the Champion dividends. This statement effectively disposes of the argument that this company is a dead weight on the community and is living on unearned increment.

Collecting Gold From Pannings

By John Saxton

[*]In estimating gold in gravels in India and West Africa, there are certain visible physical properties, such as difference in color and form due to a slight variation of hardness, which, although the eye is in good order and the judgment clear, may lead to wrong estimates until check samples are taken and the eye accustomed to the new condition of the metal. With the amount of black sand common to most alluvium mixed with fine gold, the process of forming a clean tail of gold is often a compound operation. The greater bulk or mass, the crystalline form, and the consequently greater friction of the heavy black sand, cause it to be comparatively sluggish in traveling on the surface of the contrivance used for panning and swirling the sample in the washing process, while the tendency of minute specks of gold, often polished and of a hardness which gives them a suitable form for moving comparatively quickly in relation to their density, is to work their way into the natural crevices of the black sands.

Until my sense of judgment becomes sufficiently trained to fix the relative size and weights of colors when sampling in a new field, I have for years collected samples for checks as follows:

(*a*) If a large amount of black sand is left in the concentrate and a rich tail of gold is formed, I take off the bulk with a small globule of clean mercury, manipulating so that it does not mix with the base metal in the concentrate. I then pour off the amalgam, and with a few spoonfuls of water carefully bring down about half the concentrate to a lower point in the pan. After working up, if no gold shows, I brush it off the pan, transferring to a white enameled shallow plaque about 10 inches in diameter, when the finest gold can be easily and quickly separated, the white plaque intensifying the black of the base concentrate. I then pick off again with the mercury, clean and weigh the gold.

(*b*) Pan down to a small bulk, transferring to a plaque to finish, when the gold can be quickly taken off with a small straw or glass quill. The quickest and simplest way of taking it off, when the gold is clean, is by means of a piece of ordinary wax candle worked soft with the fingers and formed into a small elongated pill or pencil. One wax candle will take and hold firmly 80 to 100 ordinary samples; the wax sets quickly and can be wrapped in thin greased tissue-paper, and will keep for an indefinite period, away from heat. Subsequently the wax can be dissolved quickly with heat and will leave the gold clean.

(*c*) Pan off to a small bulk, dry, and take out all magnetic particles with a magnet; be careful that fine gold is not lifted and carried up with the iron; roast, amalgamate, and then weigh.

A temporary roast in the field or on a wet day can be carried out quickly for minute samples as follows: Mix up nitre, charcoal, and sulphur to form a combustible mixture; make into a stiff paste, place the charge in the centre, ignite, and the roast is complete in a few seconds. A paste made of gunpowder or a small piece of dynamite, with care can also be used; in the latter cases a plate held a few inches above the charge prevents loss from sparks.

A good method is to collect the results from half a dozen pans, which greatly facilitates weighing with field instruments or portable scales. The plaque as described is in my opinion the best appliance for finishing small samples; it is light, simple to use, and requires a minimum of water, and with a common wax candle, samples of gold and other metals can be quickly and accurately taken and reduced when convenient.

Making Producer-Gas From Crude Oil

By H. A. Grine

The development of large quantities of crude petroleum in the California fields, the rapid growth of manufacturing industries, and the development of rich agricultural lands, growing out of the assurance of an abundant supply of cheap fuel, give promise of making California one of the world's greatest commercial centres. The growing demand for power at low cost for manufacturing industries, and the development of agricultural and mining properties, has attracted the attention of engineers, and has resulted in the manufacture of a number of devices for using this cheap and most convenient kind of fuel. While there are some regions where it is possible to secure power developed by hydro-electric plants at a low cost, there are many places where the introduction of low-cost power developed by oil fuel is in demand.

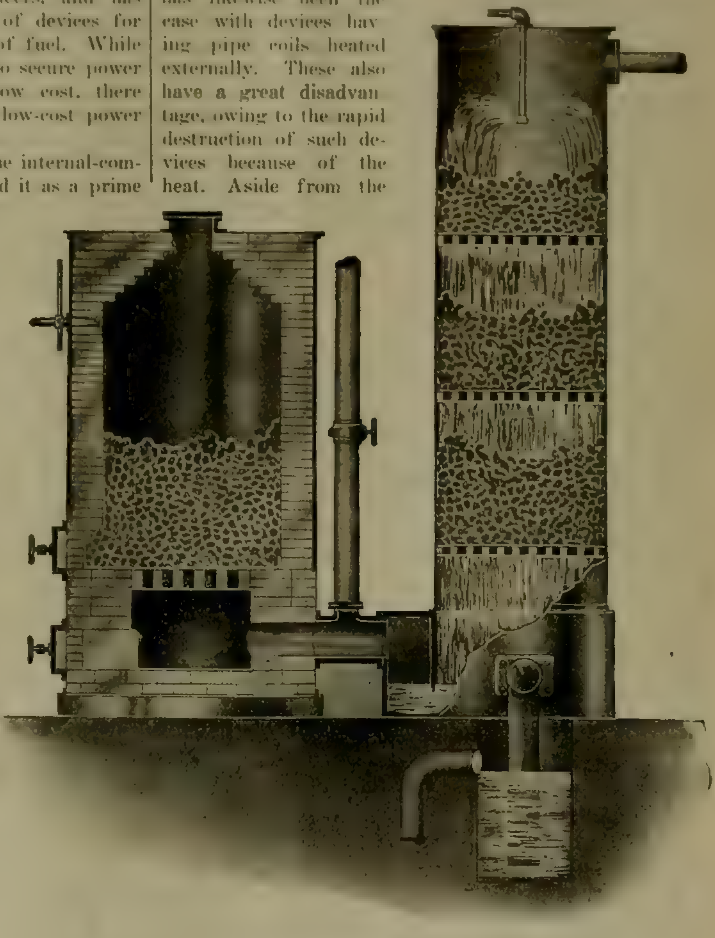
Engineers following the development of the internal-combustion engine have for some time recognized it as a prime factor in the production of cheap power, and engines for use of natural and artificial gas, kerosene, and gasoline have in recent years become well established throughout the eastern portion of the United States. However, the demand for gasoline and kerosene for purposes other than the development of power in power-plants has increased the price of these manufactured products to such an extent as to draw the attention of engineers and power users to more economical methods of generating power from the natural fuels.

Investigations conducted by the U. S. Geological Survey Fuel-Testing Plant during the past six years have definitely proved that the gas-producer in combination with the gas-engine will develop more power per pound of good fuel than a steam-plant will, and will also use, with excellent results, fuels that have been considered of practically no value. The wider distribution of the bituminous coals and their lower cost made them most desirable as fuels for gas-producers, but their volatile tarry matter presented a problem to gas engineers which had not been met with in the use of anthracite fuels. This problem has been overcome, and numerous plants are in daily satisfactory operation on all grades of bituminous coal.

The manufacture of producer-gas from the California asphaltum-base oils presented a greater problem even than did the bituminous coal, as they are composed largely of products similar to the volatile matter of the bituminous coal. The failures of early attempts at gasifying crude petroleum for use in gas-engines may in most cases be traced to a lack of knowledge of what was a suitable gas for gas-engine use, of the characteristics of the asphaltum-base oils, and of the conditions which are necessary to secure a complete gasification of the oil without a high percentage of by-product.

The numerous methods and devices for converting the oil into gas may be classified under three general heads, namely: (1) destructive distillation; (2) combustion and destructive distillation; (3) combustion alone.

Under the first heading are the devices using closed retorts or pipes set in furnaces which are kept heated by oil fires surrounding the retorts or pipes, and the large domestic-gas manufacturing units which are heated periodically to a high degree by blowing with air and oil, after which an atomized spray of oil and steam is introduced, making illuminating gas for a period. While a small amount of combustion takes place in such plants, owing to the dissociation of the oxygen of the steam, this process is practically a destructive distillation process forming considerable carbon as a by product. The failure of retort devices for developing gas for gas-engines has been due to the tendency of the heavy asphaltum of the oils to form coke in the retorts and gradually to fill them. This has likewise been the case with devices having pipe coils heated externally. These also have a great disadvantage, owing to the rapid destruction of such devices because of the heat. Aside from the mechanical difficulties of destructive distillation, devices for converting the crude oil into gas for use in internal-combustion engines, the gas made by them is not suitable to reliable and efficient operation, owing to the large percentage of hydrogen and hydrocarbon gases of which these gases are composed and the tarry matter carried to the engine.



GRINE-NELLES GAS-PRODUCER.

Under the second heading may be classed the devices in which a portion of the oil is burned continuously, creating a temperature within a chamber sufficient to cause destructive distillation of the volatile products of the oil. While such devices are a step forward in the art of making gas from crude oil for use in gas-engines, they retain many of the objections of the old retort methods. Considerable carbon is formed as a result of the destructive distillation of part of the oil. This is deposited in the gasifying chamber and outlet pipes, necessitating frequent burning-out or a periodic change of units, if continuous operation is demanded. The gas formed by such devices also contains the objectionable high hydrogen and hydrocarbon gases, and low percentage of carbon monoxide gas, so desirable for the operation of gas-engines, owing to its slow-burning quality.

Under the third heading may be classed devices in which the entire fuel is brought into intimate contact with oxygen in such manner and under such temperature conditions as to convert the greater part of the carbon of the oil into carbon monoxide. In such devices practically no residue is formed as a by-product, and a gas is formed, the combustible portion of which is composed of carbon monoxide with just sufficient hydrogen and methane to make the gas ignite readily.

In the last year the Grine-Nelles crude oil gas-producer has been designed to carry out this process with crude oil as a fuel. A commercial plant of 100 hp. capacity was erected at the William Fry pumping plant, Hollywood, California, by the Gas Power Machinery Co. of Los Angeles, about the beginning of this year. The results obtained have exceeded the guarantees made and have been in every way more than satisfactory. The plant is in daily operation, twenty-four hours per day, on a single gas unit and gas-engine, and requires little attention. The gas has a heat value of 135 to 150 B.t.u. per cubic foot, contained in the following gases:

	Per cent.
Carbon monoxide (CO)	15 to 16.0
Methane (CH_4)	4 to 5.5
Hydrogen (H_2)	6 to 8.0
Illuminants (C_xH_y)	1 to 1.2

No burning-out of carbon is required. A grate is provided in the generator, which is of the down-draft type, and on it a bed of coke is maintained. The gases formed by the incomplete combustion of the oil in the upper part of the generator, pass down through the bed of coke, where a complete gasification is accomplished. The greater part of such carbon as may be formed in the upper incomplete-combustion chamber is filtered from the gas in the coke bed serving to maintain the latter, and is retained until gasified by slow combustion as with any other solid fuel. The plant, using 14 to 18°B. crude and fuel oils, at 95c. per barrel delivered, is reported to be developing the same amount of power per gallon of crude oil as the distillate engines which it replaced were developing per gallon of distillate. The latter cost 7c. per gallon, or $2.94 per barrel, making a saving in fuel cost of 66⅔%. While this device is new, it is based on some of the best known and reliable practices in the gasification of bituminous coal.

Safe Placing of Wells

No well should be dug where polluting matter has access to it. Such matter usually comes from cesspools or privies, slops thrown on the surface, backings from hen-yards, pigpens, and barnyards, from manured fields, animals falling into the water, and filth thrown in through the open top or washed in through the plank covering or leaky casings. The matter entering through the top can be kept out by cement, iron, or other impervious curbings. The entrance of material at the bottom of shallow wells can be prevented only by placing them beyond the reach of contamination. Where any of the polluting agents are present, care should be taken to see that the well is at least 100 ft. away and on distinctly higher ground, so that both the surface drainage and the underground drainage—which generally moves in the same direction—will be away from it. On flat sands the wells should be at least 150 ft. away from any source of pollution. The importance of choosing a location safe from polluting influences is almost universally underestimated. Laying aside considerations of comfort and health, a safe well is nearly always, in the long run, the cheapest. Safety should invariably be made the first consideration instead of the last, and a small amount of care and foresight in choosing is well repaid by the prevention of a possible epidemic.—Water Supply Paper 223, U. S. Geol. Survey.

The Laccolith in Ore Deposition

By Charles R. Keyes

The almost universal tendency to consider ore-genesis to be associated with vulcanism is rendered singularly incongruous by the fact that important ore deposits are so rarely formed in connection with active volcanoes. It is perhaps for this reason more than any other that effort is made to establish kinship of some sort between certain kinds of ore deposits and certain kinds of eruptive masses. DeLaunay evidently has something of this idea in mind when he attempts to trace a close genetic relationship between local mountain making, rock character, and ore deposition. My own work in mine-examinations in western America has led me to associate many ore deposits with intrusive masses which, when carefully determined geologically, have proved to be laccolithic in character. Since Gilbert's first definition and description of laccolithic intrusions, of which the Henry mountains in southern Utah are examples, this type of bulging sill has been widely recognized. In western North America laccolithic mountains are far more common than is generally supposed. The true nature of laccoliths is not always easily established. Removal of some thousands of feet of overburden through profound erosion often disguises their real character. In other instances the probable laccolithic nature is not at once inferred because of the fact that the cover is nowhere broken and other causes may also operate.

The most familiar analogy to a cooling mass of magma that we know of is the 'freezing' of molten rock-materials in a slag-pot, or the solidifying of a ball of liquid metal from the furnace. The copious expulsion of gases evidenced by the rhythmic bubbling which goes on at the surface is justly comparable to just what takes place in the cooling of the huger magmatic body. The laccolith may be regarded as forming an intermediary stage of magmatic refrigeration between that displayed by the active volcano and that represented by the deep-seated, or batholithic, mass. The almost invariable absence of important ore deposits from the vicinity of active volcanoes is readily accounted for by the fact that in the expulsion of the soluble metallic salts in gaseous form from the cooling magma there is relatively small pressure, free access to sky, and little mingling with ground-waters. Ores due strictly to sublimation are seldom important enough to warrant mining. In the case of the deep-seated molten masses pressures are great, there is little fracturing of the rocks to furnish ready communication with the surface of the ground, and there is almost no association with meteoric waters. The main result seems to be diffused mineralization, or regional alteration, of the adjacent rocks.

Laccolithic intrusions provide many conditions favorable to extensive ore deposition. The rocks above are literally floated. This cover is rarely more than a mile thick. It is seldom fractured to sky, so as to allow ready escape of the metallic vapors as in volcanoes; nor is there complete suppression of circulation of expelled gases as in the case of deep-seated bodies. It is commonly creviced and parted around the margins of the dome. It is composed of tough rocks which effectually prevent extensive fracturing. The metallic gases and watery vapors expelled from the cooling magma pass at once into chambers and porous tracts where they are confined for a greater or less length of time, or they soon enter into the groundwater circulation since they are readily soluble. All in all, laccoliths offer ideal conditions for ore deposition.

It may be that laccoliths and volcanoes are merely slightly different phases of general vulcanism, the one occurring in tough shaly rocks and the other in brittle massive rocks. Perhaps it is only under laccolithic conditions that orebodies derived directly from cooling magmas are formed. At any rate, the definite determination of the laccolithic character of igneous masses may prove to be of great service in scientific prospecting in new and little explored mining districts the foundations of which are igneous rocks.

The Economics of Tube-Milling

By H. Standish Ball

*The modern tube-mill is a most efficient grinding machine, and is rapidly taking the place of Chilean mills, roller mills, grinding pans, and similar apparatus. Though used for many years as a cement grinder, the first reference found to its use as an ore-crushing machine was in 1892, when it was used by L. H. Diehl for grinding Kalgoorlie ores. For the next twelve years very little was heard about it, nor was it till about 1905 that it became a machine of great industrial importance on the Witwatersrand. During the last six years the development of its working details has been rapid, for it was but a step from the iron ball of the ball-mill to the flint pebble, another from the one manhole in the shell centre to two at opposite sides, and one more from the iron lining to the silex, set flat in cement, then back to iron or steel plates, and from these to the honeycombed and ribbed lining. Where formerly silex linings lasted three months and required three weeks for renewals, the life is now twelve months, and replacements are made in two eight-hour shifts. At first the mills were laboriously charged by removing a single manhole cover and throwing in loads of pebbles; next a bin was built over the mill to chute the pebbles rapidly into the mill and thus save time. Such a means as a fixed spiral in the discharge end, or a feeder large enough to pass the pebbles into the feed end of the mill, has materially lessened the old troubles, and tube-mills can be run 97% of the possible running time. With the simplified method of feeding now adopted, the modern operator is gradually dispensing altogether with the flint pebbles, their place being taken by the lumps of ore itself in Rand practice; thus the cost of the pebbles is saved and incidentally the capacity of the plant is increased 1 per cent.

Before giving an example of the process followed out, a few details of the present day tube-mill will be interesting, the mill taken being one of a series used by the Eckstein group on the Witwatersrand. The present standard size mill is 22 ft. long by 5 ft. 6 in. diam. Silex liners are used, 6 to 7 in. thick when new; thus the internal diameter of the mill when lined is about 4 ft. 6 in. The internal volume of a newly-lined tube-mill is 350 cu. ft., the volume of the shell without the lining being 523 cu. ft. The pebble load is a varying factor increasing throughout the life of the liner; with new liners the pebble load is 8 to 9 tons, with worn liners (liner 3 in.) the load is 12.8 tons, and may reach 14 tons just before the liners are removed. When the mill is stationary, the level of the pebbles is 3 in. above the axis of the rotation of the mill; with new liners the volume occupied by the pebbles is 200 cu. ft. Ore pebbles are now used to a large extent, and the ore is roughly sized to 4-in. cubes before being fed in.

The capacity of this mill is still a debated point, but the following result of one month's working on a typical Rand installation is interesting, the battery screens used being 12 mesh per linear inch. The equivalent of 400 tons of dry sand is passed through the mill in 24 hours, the pulp containing 38.5% moisture. In order to get the best results from the plant in question, the mill should produce 130 tons of product to pass through a screen of 90 holes per linear inch per 24 hours.[1] In addition to the tonnage of sand fed in, there is a weight of 7 tons of banket ore used per 24 hours in place of pebbles. One 125-hp. electric motor is required per tube-mill, though only about 75 to 90 hp. is actually absorbed when once the mill is running uniformly. The number of revolutions per minute is 31 to 32.

As an example of the rapid installation of tube-mills in the Transvaal during the past year, it is interesting to note that whereas, in 1909, 136 tube-mills and 9580 stamps were installed, in 1910 the former were increased by 39.7%, against an increase of 1.6% of the latter. Modern tube-mill plants in other parts of the world differ little in their principle of working, only having variations in minor details; for example, in American and Australian practice a product to pass through a screen of 200 holes per linear inch is frequently required.[2]

The function of the tube-mill as a fine crusher in connection with stamp-milling and cyanidation can be best shown by giving a typical crushing circuit, the one chosen being that adopted by some of the mines of the Gold Fields companies on the Rand. With this system only those particles of the tailing pulp which are sufficiently light to be carried over the hydraulic classifier pass away direct to the cyanide plant, the remainder being diverted to the tube-mill. From the stamps the pulp is taken by means of a pulp elevator to a cone classifier which separates the slime from the sand, the former going direct to the cyanide plant, while the latter is conveyed into the tube-mill by means of a spiral conveyor. From the mill it passes over amalgamated plates to a second cone classifier, where it is re-classified. The number of primary classifiers per tube-mill has been reduced to one, without interfering with efficient classification. The cones used are 6 ft. diam. by 9 ft. deep and contain two diaphragms 14 and 3½ in. diam., the upper one being 5 ft. 5 in. from the top of the cone, and the lower 1 ft. 3 in. from the bottom; the purpose of these diaphragms is to provide a means of obtaining a uniform feed of the pulp. The diameter of the outlet to the classifier is $2\frac{3}{16}$ in. and its capacity is about 400 tons of sand with 26% moisture per 24 hours.

At a comparatively early stage in the development of the tube-mill it became evident that high efficiency could only be obtained by feeding a sand containing a minimum of slime, and by reducing the percentage of water below the 50% first taken as a standard. This demand has resulted in the invention of a number of classifiers and thick-pulp feeds, of which the Caldecott diaphragm cone, mentioned above, is the most satisfactory. Up to the present, however, no efficient means has been found for providing an exactly uniform mixture of coarse and fine sand in the mill feed. The diversion of the fine ore from the bins directly to the tube-mill, without passing it through the battery, is one of the best suggestions yet put forward for increasing the efficiency of the stamp-tube-mill combination, and a start in this direction has already been made, with satisfactory results. It is remarkable to what a great extent fine battery crushing has given way to coarse, and it is possible that stamps may ultimately be superseded by other types of coarse crushers when the ore is to be finally crushed in tube-mills.

There are two kinds of crushing which take place inside a mill: (*a*) Crushing by shock, due to the impact of pebbles. (*b*) Crushing by abrasion, due to the rolling and rubbing of the pebbles, and contact with the lining of the mill. One form of crushing or the other will predominate, according to the type of mill used, the pebble load, and other conditions. Although the consideration of the tube-mill from a mechanical point of view is fairly simple, much experience is necessary in order to get the best results from it. For this reason attempts have been made to determine the most economical conditions under which tube-mills can be used, taking into consideration the desired fine grinding as the end to be obtained with the least consumption of power and smallest wear on pebbles and lining. These three points seem to depend on the following four factors:

1. The pebble load.
2. The tonnage dealt with, and the character of the sand.

---

*Abstracted from the *Bulletin* of the Institution of Mining and Metallurgy.

[1] Screen equal, approximately, to 80 mesh I.M.M. screen.

[2] Screen equal, approximately, to 200 mesh I.M.M. screen.

3. The thickness of pulp.

4. The diameter of the mill and the number of revolutions.

A change in any one of the above will cause a change in two, and sometimes all three of the points given.

The investigation of these interesting points is obviously desirable, and the subject was an eminently suitable one to be undertaken by a laboratory such as that possessed by McGill University, owing to the freedom from interference with continuous tests which would be inevitable on ordinary commercial plants. The rock chosen to be experimented on was an elaeolite or nepheline syenite, of a hard uniform character, composed essentially of orthoclase, elaeolite, and hornblende, and was obtained from the Outremont quarries, Montreal. This rock was used, as it was considered to be typical of a hard, compact ore.

Four investigations were decided on, as follows:

Series I.—In which the feed was to be varied, the moisture, pebble load, and revolutions per minute remaining constant.

Series II.—In which the moisture was to be varied.

Series III.—In which the pebble load was to be varied.

Series IV.—In which the pebble speed was to be varied.

The other three factors remaining constant in each case. For the details of these tests, which were made in a 3 ft. 5 in. by 4 ft. 8 in. tube-mill constructed from an old chlorination barrel, reference should be made to the original paper, as given in No. 83 of the *Bulletin* of the Institution of Mining and Metallurgy, August 30. The following summary will be of interest:

Feed Tests.—From the results obtained it was found that a feed of 18 tons per 24 hours is the most efficient one for the laboratory mill, any larger feed apparently causing the crushing efficiency, as well as the relative mechanical efficiency, to decrease. This is a most interesting point, as a critical feed is indicated, above which it seems probable that the fine-grinding properties of the mill decrease in proportion approximately to the increase of feed. With a feed of 23 tons per 24 hours, only 3.79 tons of −120 grade per 24 hours were obtained, whereas the same fine-grade output would be obtained by crushing only 18 tons through a similar period; this fact shows that the critical feed has been passed between these two amounts.

The theory of a critical feed may have an important bearing on modern practice, as it would seem that more efficient working, with a greater output of slime, would be obtained if a smaller feed were used. In South Africa the tendency at present is to increase the feed in the 5½ by 22 ft. mills, and although they are now feeding at the rate of 400 tons per 24 hours, the belief is held that even heavier feed would result in increased grinding. The above results show the danger of carrying this too far. Using these figures as a basis and roughly calculating the feed for the laboratory mill, it appears that a feed of about 25 tons per 24 hours should result in more grinding than with a smaller feed, whereas the experimental results obtained in these tests indicate that this feed is less efficient than a smaller one and that the most efficient feed for this mill approximates 18 tons in 24 hours. Admitting the discrepancy of comparing two mills differing so radically as to size, it is at least of interest to note that, if any analogy can be drawn, the indications are that the South African mills are overfed and that a feed of about 300 tons instead of 400 tons per 24 hours might result in both increased grinding and efficiency.

Moisture Tests.—The most prominent feature of these

* Most efficient test of series.

tests is the great efficiency of 37% moisture over all others. This fact corresponds remarkably well with tests carried on in other parts of the world. In those conducted by Walter Neal, results seem to prove the fact that the ideal dilution is in the neighborhood of 39% moisture, although he inclines to the belief that this critical point will vary with the nature and size of the mill. The results of these tests tend to disprove this belief.

Sherrod, experimenting with tube mills at the Guerrero mill, Real del Monte, found that the grinding efficiency increased with the percentage of solids in feed, up to about 55 or 60%, corresponding to 45 to 40% moisture. G. O. Smart[4] claims that in the tests carried out on the Rand he found that 38.5% moisture is the most efficient, while H. W. Fox[5] discovered that, taking the power consumed in conjunction with the fine-grinding, the most efficient moisture would be 39.6%. It will be noticed that all these critical points are from 1 to 2% higher than the one found by the author, but this seems to be explained by the fact that the sands used, being 18 mesh, were of a finer nature than those commonly used in practice. It has been suggested by J. W. Bell[6] that the critical moisture point depends upon the percentage of voids in sand, and that in all probability when the percentage of moisture is numerically equal to the percentage of voids in the sand inside the mill, the moisture is critical. This theory is of interest in that it indicates that sand-feeds with higher or lower percentages of voids may have higher or lower critical moistures.

The second interesting feature of these tests was the use of the 'transition samples' for obtaining intermediate moisture efficiency. This appears to be a practicable method of obtaining a number of points of efficiency and power at various intermediate quantities of moisture, by simply running a long continuous test and at equal periods changing the moisture without stopping the mill. In the compilation of data and curves this should be of great service both as a check on the work and for effecting a substantial economy in time and labor.

Pebble Load Tests.—The result from these tests indicated that the most efficient pebble load is about $^7/_{16}$ of the volume of mill (or for this mill 1030 lb.), whereas, disregarding power, the most effectual 'crushing load' is about 0.6 of the volume; which corresponds to present Rand practice. Whether it would pay to sacrifice power and gain fine grinding, or *vice versa*, would, of course, depend upon conditions at the plant.

Speed Tests.—These tests were most interesting, as they proved conclusively that 37 r.p.m., at a peripheral speed of 333 ft. per minute, was the most efficient, both in relative mechanical efficiency and grinding efficiency, thus demonstrating that at that speed the grinding was decidedly better, and the power required less. It was seen that if this speed of 37 r.p.m. is exceeded or decreased, the crushing effect of the pebbles is much reduced, while the power necessary to drive the mill is increased. In connection with this efficient speed, it is interesting to compare it with that obtained from various formulæ.

Davidson gives as the best practical speed $N = \frac{300}{\sqrt{D}}$ in inches, while White derives a formula $N = \frac{34.21}{\sqrt{D}}$ in metres. ($N =$ speed, $D =$ diam. of mill.) Richards gives 38 r.p.m. as the best speed.

The results are set forth below:

Davidson.	White.	Richards.	By experiment.
34	39	38	37

Thus the result obtained from actual experiment corresponds very closely to the mean of these results.

Calculation of Data.—It is my personal belief that there is a possibility of deducing from the curves obtained from the different tests the probable results that would be derived by running the mill under different conditions. An example of this was shown in the feed tests, where the probable data for Test A were deduced from the curves of Test B. The conclusion from this theory appears startling, for it seems that if one complete set of tests is run with a constant feed, the other factors being varied and the respective curves obtained, it is possible to deduce from them all the necessary information regarding any feed, provided that one test at that particular feed had been previously carried out. As a case in point, it was desired to know what the relative mechanical efficiency for a feed of 7.2 tons per 24 hours would be, with a moisture of 35%, speed of 37 r.p.m., and pebble volume 0.5, a test with 38% moisture having already been run on this feed. The moisture efficiency curve for Test B was used, and the following data extracted:

Moisture. %	Feed. Tons.	Efficiency. %	Difference. %
38	12.6	7.02	0.27
38	7.2	4.45	
35	12.6	6.75	
35	7.2	x	

$$\text{Hence } \frac{0.27}{1} \times \frac{4.45}{7.02} = 0.18$$

$$\therefore = 4.45 - 0.18 = 4.27.$$

By actual experiment the efficiency was found to be 4.32, a difference of 1.1% between the theoretical and the actual result.

Transition Samples.—The calculation of intermediate points of efficiency by the method of transition samples and power readings is of great interest, as the efficiency and power required can be found for any intermediate point of moisture, feed, etc., between the limits of any two tests. This period was found with great accuracy by means of nine tests, the time required being checked by both power readings and screen analyses.

SUMMARY

The more important features disclosed in this investigation may be summed up as follows:

(1) The determination of a rate of feed, which if increased or decreased caused the efficiency of the mill to diminish in a marked manner, and consequently may be defined as a critical feed rate.

(2) The determination of a well-defined critical percentage of moisture in the feed.

(3) The determination of a critical speed for the laboratory mill (34 in. diameter).

(4) The determination of a critical pebble load for this mill.

(5) The determination of the length of time required by the mill to assume a uniform condition following a change in adjustment. This is defined as the transition period of the mill.

(6) The substantial corroboration of the author's hypothesis that samples and power observations taken at intervals during the transition period may be used to determine the efficiency of the mill for the calculated conditions at the times the samples were taken. These samples are called transition samples in contradistinction to normal samples taken after the mill has assumed a uniform condition.

(7) A method by which the data and curves obtained in one series of tests may be transposed and applied, as far as possible, for the purpose of securing further light on the phenomena disclosed by a second series.

MANGANESE ores were mined in 1910 only in Virginia and Arkansas. The production, however, increased from that of 1909, being 2258 tons, valued at $22,892 for 1910, as against 1544 tons, valued at $19,675, for 1909. Large quantities of manganese are imported. These and other statistics of production compiled by E. F. Burchard of the U. S. Geological Survey are contained in an advance chapter from 'Mineral Resources of the United States for 1910.' Of manganiferous ores, which, however, contain only a small percentage of manganese, the production was much greater, amounting in 1910 to 619,735 long tons. Manganese is chiefly used in the production of ferromanganese and spiegeleisen, but has a great variety of other uses and is in constant demand.

The Thiogen Process for Reduction of SO_2 in Smelter Fume

By Stewart W. Young

The difficult situation of the smelting industries of the United States at the present time is too generally understood to need any extended discussion here. The fumes which escape from the various furnaces, especially from roasters, carry in many cases quantities of substances that are destructive to vegetation and in some cases poisonous to stock. The result is that in some cases it becomes impossible to carry on the two industries of agriculture and smelting in the same district, and a number of important smelters have been enjoined from operating by court orders issued on complaint of farmers.

The most important of the deleterious substances contained in smelter fumes are arsenic compounds, sulphur trioxide, and sulphur dioxide. Various devices are at present in successful use for handling the first two of these substances. Both the bag-house systems and the Cottrell apparatus are able to remove the arsenic and the sulphur trioxide from the fumes; but neither is able to remove sulphur dioxide. The reason for this is that the sulphur dioxide is present in the form of a true gas, while the above-mentioned methods are able to handle only substances in the form of solid particles, which is the form of occurrence of the arsenic and the sulphur trioxide.

The only device for mitigating the sulphur dioxide evil that seems to be in use is that of diluting the stack gases with large quantities of fresh air so that the concentration of the sulphur dioxide is at a minimum. The benefits of this method are probably considerable where comparatively small amounts of sulphur dioxide are released, but in case very large quantities are released, its beneficial action is at least questionable. It might be imagined that since sulphur dioxide is quite readily soluble in water, the stack gases might be sprayed, and the sulphur dioxide eliminated in this way. But the solution of sulphur dioxide is equally as poisonous as the gas itself, and there is no practicable way of getting rid of it. The problem, then, seems to narrow itself down to some process for chemically converting the sulphur dioxide into some other substance that may be utilized, or that at least is innocuous. To the chemist there are two, and only two, means which seem at all feasible for the accomplishment of this purpose. They are:

(1) The conversion of the sulphur dioxide into sulphuric acid;

(2) The conversion of the sulphur dioxide into free sulphur or brimstone.

There are various methods whereby the first of these reactions may be brought about, and these are used in some places, as, for example, at the Ducktown smelter. The chief obstacle to its extensive use is the comparatively limited market for the sulphuric acid. It is practically impossible to store the enormous quantities of this substance that would be produced, and still more is it impossible to throw it away in considerable quantities. Like sulphur dioxide, it will kill vegetation, and fish. The possibility of converting the sulphur dioxide into free sulphur seems to have received very little attention up to the present time. Sulphur is an innocuous substance, and, provided a reasonably economical process is devised, its elimination from smelter gases in this form would seem to offer an ideal solution of the problem. Supplies of sulphur for many years to come would be established, and the present serious check to the smelting industry would be overcome. It is the purpose of this paper to give a brief sketch of a process whereby this result may be accomplished.

The elementary chemistry involved in the reduction of sulphur dioxide is extremely simple. The reduction may be accomplished by means of carbon or by means of hydrogen, or, still better, by means of compounds of carbon and hydrogen, such as crude petroleum and the like. Assuming, for simplicity's sake, a hydrocarbon of the formula CH_2, the reduction should proceed as follows:

$$SO_2 + CH_2 = S + CO + H_2O$$

That is, the carbon is converted into carbon monoxide, the hydrogen into water, while the sulphur is left in the free state. It may be stated at the outset, that since the conversion of sulphur dioxide into free sulphur and free oxygen is a reaction that involves an absorption of energy, such reaction cannot be accomplished without supplying such energy. Thus there will always, of necessity, be a fixed cost for materials used in any process operating in this way, and no purely catalytic process can accomplish the result. In the above reaction the energy used is supplied by the hydrocarbon.

While from the above statement of the case, the problem seems to be readily solved, this is, as a matter of fact, not the case. Very serious difficulties stand in the way, and these are partly chemical and partly mechanical. The more important of these difficulties are the following:

(1) The presence of free oxygen in the gases to be treated, bringing about a serious waste of hydrocarbon.

(2) The slowness and incompleteness of the reactions even when oxygen is not present.

(3) The fact that all the available energy of the hydrocarbon is not utilized, since carbon burns to monoxide instead of dioxide.

All of these difficulties have been met and solved in the laboratory, and although it is not possible at present to discuss in detail the devices whereby these things have been accomplished, there is no objection to making public a general sketch of the main points of the process.

The Thiogen process has been put into a practical form by carrying out the reaction discussed above in an indirect way. The sulphur dioxide is first absorbed by means of a basic sulphide, either in the wet or the dry state, the one chosen for most work being calcium sulphide. The reaction which takes place here results in the formation of calcium sulphite and free sulphur. The presence of oxygen in the gases does not interfere in this reaction to any appreciable extent. That is, the reaction with the sulphur dioxide is very rapid, while that with oxygen is very slow.

The second step in the process consists in removing the free sulphur from the calcium sulphite, which may be accomplished by distillation or other suitable means. The third step consists in the reduction of the calcium sulphite by means of hydrocarbons. This reaction results in the regeneration of calcium sulphide which again enters into the reaction in its first stage; that is, it is used for the further absorption of sulphur dioxide. Under ordinary conditions the reduction of the calcium sulphite to sulphide is a matter of considerable difficulty, the reaction being rather slow, even at high temperatures and resulting in the conversion of the carbon into monoxide instead of dioxide as is desirable. A method has, however, been devised whereby the reaction takes place readily even at relatively low temperatures, and whereby the complete combustion of the hydrocarbon is assured. An adaptation of the process has also been devised whereby gases which are free, or nearly free, from oxygen may be handled with a much increased mechanical efficiency. In fact, the fundamental principles upon which the process depends offer very considerable possibilities of adaptation to suit special conditions. Incidentally, considerable progress has been made toward adapting the process to the recovery of flue-dust.

The reactions involved in the indirect method, expressed in chemical symbols, are as follows:

(1) $2CaS + 3SO_2 = 2CaSO_3 + 3S$

(2) $2CaSO_3 + 2CH_2 = 2CaS + 2CO_2 + 2H_2O$

To anyone versed in chemistry, it will appear at once that here, in an indirect manner, is accomplished precisely what is done by the more or less theoretical equation given in the earlier part of this article, except that here the combustion of the hydrocarbon is more complete. In any event, the fixed cost of the process is a quantity of a reducing agent (here hydrocarbons) sufficient to reduce the sulphur dioxide.

Another reaction which is made use of to some extent depends upon the fact that when sulphur dioxide is passed over a heated sulphide ore, the sulphide ore is roasted, and that almost as completely as if air were used. Expressed chemically, this reaction is as follows:

$$3FeS + 2SO_2 = Fe_3O_4 + 5S$$

In this case the ore itself becomes the reducing agent, and the fuel oil charge is avoided. The reaction is, however, slow, and requires external heating to give any great capacity. On the other hand, it is found to be a valuable adjunct to the other processes above described.

The ultimate efficiency in the application of these principles will naturally be greatest in a plant in which the adjustment is so made that the greatest amount of sulphur dioxide may be handled with the least expenditure of hydrocarbon, and with the least expenditure for installation and operating expenses. Whatever may be the most economical plant for accomplishing this purpose can be told only from actual operation, but this much at least seems quite certain, that, from the chemical point of view, the maximum economy of these processes must probably be the maximum economy attainable in any process for the production of free sulphur from sulphur dioxide. The reasons for this are briefly as follows:

(1) A certain perfectly definite expenditure of energy in the form of a reducing agent is absolutely necessary to produce sulphur from sulphur dioxide.

(2) The processes above discussed operate by applying this energy in the cheapest known form, namely, hydrocarbons, and further take advantage of a certain possible saving through a reduction by means of the ore itself.

Thus in order to devise a process whose theoretical chemical efficiency is greater than that of the Thiogen process, it will be necessary to discover a reducing agent cheaper than the hydrocarbon oils, which seems not likely to happen. It would not be fair to close this article without expressing my deepest thanks and appreciation to Messrs. John T. Overbury, H. G. McMahon, and Hamilton Sanborn of San Francisco, whose assistance, financial as well as personal, has made possible the development of the Thiogen process to its present state.

Mine Safety Demonstration

Under the joint auspices of the American Red Cross, Pittsburg Coal Operators' Association, and the United Mine Workers of America, and under the management of the United States Bureau of Mines, a mine safety demonstration will be held at Pittsburg, October 31. Beginning at 9 a.m. at Forbes Field (Pittsburg), Pennsylvania, an exhibit of skill in first aid to the injured will be given by teams of five miners from various coal operations in the United States, five separate events to be exhibited. At 11 a.m. demonstration by the Bureau of Mines in steel-lined mine gallery 200 ft. long, of a permissible shot, followed by an explosion of black powder detonated in the presence of coal dust, with a resulting explosion of coal dust ignited by the non-permissible explosive. This will be followed by demonstration of rescue work; men equipped with oxygen helmets will enter the gallery while still filled with smoke and poisonous gases, will bring out injured men, and give them artificial respiration and first aid. Also a demonstration of dangerous practices within gaseous or dusty mines.

At noon President Taft will deliver the prizes, and short addresses will be made by the President, J. K. Tener, Governor of Pennsylvania, Walter L. Fisher, Secretary of the Department of the Interior, and others.

Porcupine

An interesting glimpse of conditions at Porcupine late in August is given in a private letter from one of the young men at work there, from which we are privileged to make the following extracts:

The big fire is now an old story, and no doubt you saw the articles in the Western papers. It was big all right, and I was up to my neck, both mentally and physically. The loss of life was not as bad as the reports, but the property loss was great. The Dome suffered heavily, as the mill was within two months of completion. Every building and most of the machinery was destroyed. The presses, after a little replacing and retouching, can be used; the tanks can be straightened out and repaired, but 75,000 rivets will have to be cut out by hand. I stayed to fight an impossible fight until too late to get to Lake Edwards and had to run before the fire to a little pond by the powerhouse. There I found 56 others—a regular Heinz pickle vat, with all the varieties. We had a hard time while the mill was burning, as you may well imagine, coming up out of the cold water for a breath of hot smoke and cinders and then ducking down again. The worst was over in about half an hour, but the rest of the night was no picnic. I was pretty well used up and my eyes were bad for a while, but am all right now. I lost all my personal belongings, and it is surprising how much clothing, books, notes, instruments, and incidentals you have had in your trunk and suitcase when they disappear.

OUTCROP AT DOME MINE.

Within a week the Dome had a hundred men at work, and the wreckage was all pulled out. The company arranged with the T. & N. O. railroad to put in a 7000-ft. spur, so men were put to work at once building the grade. The steel is now in and I suppose the ballast will follow shortly. The new concrete mixer is being placed. Most of the concrete foundations were found uninjured, except that changes were necessary to furnish footings for the steel columns of the new buildings. The battery blocks were blown out, but will be replaced. At present there are about 250 men at work, divided as follows: 40 men on the mill, clearing out, overhauling pumps and presses, building derricks, concrete plants, and store-houses; a gang clearing stumps from land; another prospecting; another fixing up the shaft, and a riveting gang taking down tanks and boilers. In prospecting they have uncovered as fine a showing as I ever saw. In a trench they found a vein of quartz about 10 ft. below the surface and followed it about 30 ft. In four different places the quartz is shot full of gold, and at one place a lump of metal as big as your little finger sticks out. There were fully 100 visitors there in less than no time. Two weeks after the big fire a cold rain put out all bush fires, and now the weather varies from warm and dry to cold and wet. The thermometer dropped to about 40° a few days ago, but it still has 80° to go before the 'big cold' is on. The aurora borealis is visible once in a while and is a fine sight. It is getting colder noticeably of nights, and we will all be in tents for at least a month yet. The townsite for the permanent camp is ready and building material should be here shortly. The mosquitoes do not bother me much, but there are many other varieties of flying biters and stingers around, and of these the common fly is the worst just now and we are anxious for a cold snap to finish them. There seems to be no malaria, but some typhoid. We have had one death and several cases. I just escaped it myself, but am now all right again.

New York Metal Markets

The statistics of the Copper Producers' Association for August make possible several very interesting comparisons. In the first place, it is noteworthy that the much-heralded increase of production has not yet materialized, the output for eight months this year being 963,320,648 lb., compared with 963,440,171 lb. during the corresponding period of 1910. According to L. Vogelstein & Co., foreign, domestic, and total deliveries compare as follows for the eight months:

	Foreign.	Domestic.	Total.
1911	497,705,878	454,203,464	951,909,342
1910	423,609,695	512,715,342	936,325,037
1911 over 1910	74,096,183	....	15,584,305
1910 over 1911	....	58,511,878	....

Going back to the beginning of the Producers' statistics, foreign, domestic, and total stocks compare as follows:

	Foreign.	Domestic.	Total.
Dec. 31, 1908	103,548,480	122,357,266	225,905,746
Dec. 31, 1909	228,417,280	141,766,111	370,183,391
Dec. 31, 1910	163,413,280	122,030,195	285,443,475
Aug. 31, 1911	130,791,360	133,441,501	264,232,861

From the above it will be seen that after nearly three years of nervous and erratic markets laboring constantly under the fear of excessive supplies, there is 11,000,000 lb. more copper in this country and 27,000,000 lb. more abroad; a total of 38,000,000 lb. or almost exactly one week's supply. Total world's stocks at the end of August 1911 were less than 50 days' supply. A simple calculation will show that at the present rate of accumulation we shall have two full months' supply by the middle of 1915. Nevertheless, apprehension that the market will shortly be glutted with copper will doubtless continue to exert a disquieting influence. While, as above stated, there is no increase to date in the domestic output, it is quite likely that some new copper will come on the market between now and the end of the year. Even so, assuming the same rate of foreign and domestic consumption as heretofore, we shall finish the year with stocks not greatly changed from the beginning, and certainly much less than two years ago. With any approach to good business in this country, the additional supplies will readily be absorbed. As to the future, L. Vogelstein & Co. look for at least a maintenance of the present volume of business and possible improvement. Dun's Review for last week says:

"Steady improvement in business conditions is indicated by most of the reports which come from the leading industries and from trade centres. This is further confirmed by the gain in bank clearings, the reduction in number of idle cars, and the increase in pig iron production. Apparently there is a much more optimistic sentiment regarding the cotton and grain crops, in spite of the recent Government reports of conditions; and with the prospect of fair average farm returns, low stocks of goods on the shelves of distributing merchants, and an abundant supply of money, the fall season is opening with a considerable growth of confidence."

Reference is also made to improved conditions in the textile and leather trades, to the great activity of building, and to our excellent foreign commerce. In spite of large shipments of steel and iron, unfilled orders on the books of the steel corporation have increased. Everything considered, there seems no reason to be bearish on copper. It must not be forgotten that mines are closing as well as opening.

The lead market is without particular feature, and prices have fluctuated within narrow limits. In New York desilverized remains at 4½c. and in St. Louis at 4.42½c. Missouri brands are selling at 4⅜c. St. Louis, which enables them to compete with desilverized in Eastern markets. Stocks of foreign lead in bonded warehouses have been cut in half; in spite of which the European market has advanced. Trade in lead products is reported active, and a continuance of sound and healthy markets can be expected.

Spelter, after selling at 6c., St. Louis, declined to 5¾c., but not much metal changed hands at the lower prices, and the market is now strong at 5.90c. or better. Spot spelter is in reality scarce and commands a premium over futures, instead of the reverse, as is usually the case. European dealers are bidding parity of 5¾c., East St. Louis, in this country, and would take large quantities if available. Such being the case, lower prices are not likely, but rather an upward movement with any improvement in demand.

Blast-Furnace Slag Cement

Portland cement is made by one of the subsidiaries of the United States Steel Corporation, the Universal Portland Cement Co., from limestone and granulated blast-furnace slag, the latter being the product of the bessemer furnaces of the Carnegie Steel Co. Large bins approached by elevated tracks at one end of the raw-material mill provide the storage room for the raw material. From these bins the limestone is fed directly into gyratory crushers, which prepare it for the dryers into which the stone then enters. The slag is also fed into separate dryers, all of which are maintained at a sufficiently high temperature to drive off all the moisture. After passing through the dryers each of the raw materials is conveyed into separate ball and Williams mills, where rolling and impact reduce them to extreme fineness. The two materials are then carried to separate hoppers from which they are drawn off and properly proportioned by electrically operated weighing devices. The mixture of slag and limestone, already a powder, is then passed into tube-mills where it is thoroughly mixed and completely pulverized. The next step is the calcination of this raw mixture in rotary kilns. Leaving the rotary kilns the clinker, produced by the burning, is dropped into storage pits where it is cooled and cured. Electrically operated cranes then carry the clinker to the finishing mill, where it is passed through jaw-crushers to Kent mills and then over Newyago separators. After the addition of a certain quantity of gypsum, which is done by means of an automatic device, the material again passes through the tube-mills similar to those used in finishing the raw material. Being now ground, the cement passes on to a belt-conveyor and is distributed into the various bins of the storage-house. The cement in passing from the finishing mill into the storage-house is automatically sampled, from which samples the various tests for quality are made in the laboratory.

GEORGIA'S gold production in 1910 was 1722.25 fine ounces, valued at $35,602, and of silver 335 fine ounces valued at $181, according to H. D. McCaskey, of the U. S. Geological Survey. Compared with the figures for 1909, the production of 1910 shows a decrease in gold output of $25,018, and a decrease in production of silver of 21 ounces, but an increase in value of $76. There was no production of copper or lead ore in Georgia in 1910. The placer gold output was 880.96 fine ounces, and the remaining production of gold, all from quartz ores, was 841.29 fine ounces. This shows a considerable increase of placer gold, but a much larger decrease of gold from the deep mines, owing mainly to the idleness of the famous Franklin mine in Cherokee county. The silver output from placer gold in 1910 was 84 fine ounces and from quartz gold 251 fine ounces. There were 13,562 short tons of silicious gold ore mined in Georgia in 1910, with an average recoverable value of $1.29 per ton in gold and silver, against 8549 tons in 1909 with an average extraction of $5.18 per ton. There were 23 placers and 8 deep mines producing in 1910, against 15 placers and 14 deep mines in 1909. Placer mining has been on the increase in Georgia for the past two years, but deep mining in general has not kept pace.

An Important Development at Angels, California

One of the most noted groups of mines in California is that at Angels, in Calaveras county. In the sixties these mines had attracted much attention and some of them had been large producers. The most important of the groups, beginning at the north end, are the claims now consolidated by the Sultana company, including the Bovee; the Angels mine, the Lightner, the Utica, and the Stickle. West of this group is a second group, which includes the Madison and Gold Cliff mines. It is the area from the famous Utica-Stickle northward, however, that has been the most productive, and which now, after an idleness on the part of some of the mines, again gives promise of yielding additional millions in gold. An unusual geological condition exists in these mines, which strangely has only recently come to be understood, or its importance appreciated. The main producing vein coursing through the mines from the Bovee to the Stickle, is a zone of steeply inclined chloritic schist, locally highly silicified in considerable masses and impregnated with gold and auriferous sulphides, principally pyrite. This zone of mineralized schist is intersected by a second vein which lies to the west of it. This latter vein strikes more nearly to the north than the former, and also has a much flatter dip—about 45°. It therefore cuts the mineralized zone of the Bovee-Stickle group both in strike and dip, and is later than the schistose vein, as it faults the latter. The pay-shoots which have made the schist mines famous lie above the plane of this faulting vein. As the intersection of these two important veins occurs at the surface in the Bovee mine, the pay-shoots were found in this property at and near the surface, and the entire zone was worked before 1868 by an open pit which extended the entire length of the property, producing about $600,000. Some ore was also mined from the later vein, which was found to be profitable in spots, particularly near the surface. The condition in the Angels mine was essentially similar to that in the Bovee, though, as already indicated, the faulting vein lies at an increasingly greater distance to the westward, proceeding southward along the schistose vein. It is also deeper to the plane of intersection in that direction. The Angels mine was extensively and profitably worked in early days, to a depth of about 300 to 400 ft., at which depth the heavy masses of talcose and chloritic schist and barren quartz of the faulting vein were reached.

NEW SHAFT, LIGHTNER MINE.

The Lightner, Utica, and Stickle, lying south of the Angels mine in the order named, were worked with varying though not great success, in the early days, and finally were abandoned and remained idle for years until early in the eighties, when work was renewed on each of them. It will be understood that, owing to lack of knowledge of the peculiar geological conditions at these mines, the work of sinking was not extensively undertaken until rich ore was found in the eighties in the Utica mine, near the north shaft, at a depth of about 600 ft. Here the pay-shoot was found to lie upon a heavy stratum of talc schist which was assumed to be the foot-wall, and for years these mines were worked under this erroneous impression. A few years ago it was learned that the schistose zone, which had been so highly profitable in the series of mines through which it passed, was resting on a fault plane, that the heavy stratum of talc schist with its nearly barren lenses of included quartz, was merely a vein later than the Stickle-Bovee vein, and had displaced the latter. This led to the shafts of the Angels, Lightner, and Utica-Stickle mines being sunk through the faulted zone, and the discovery to the eastward of what is now presumed to be the downward continuation of the faulted schistose vein. The Utica workings entered this ore on the 1200 ft. level, and have been in it to the present lowest level, the 1700. In the Angels mine pay-ore has recently been found in a winze sunk from the 950-ft. level. This ore is said to mill $6 per ton, and the vein is 20 to 30 ft. in width. These recent discoveries have greatly stimulated activity among all the mines of this group, and other quite as important discoveries are anticipated.

Westward from the Utica-Stickle mine, and distant about 2500 ft., is the Gold Cliff mine, the vein of which dips at angles varying from 50 to 35° to the eastward, and it is estimated that the Gold Cliff vein will intersect the Utica vein somewhere between 2500 and 3000 ft. in depth, in view of which the main shaft is to be sunk to that depth in search of the intersection of these veins. This proposed development is in anticipation of the possible recurrence of large bodies of payable ore above the plane of intersection, similar to those which have previously been found nearer the surface.

Mr. Pinchot Visits Alaska

Alaska is entertaining many visitors this summer, and among the number is Gifford Pinchot, whose trip is particularly significant in view of his prominence as a conservationist. According to the *Valdez Daily Prospector*, he made the following statement as to his plans and purposes: "My object in visiting Alaska at this time is, first, to meet the people and learn their views; and, second, to see all of the country I can in the time I have. I came here to get information at first hand, and to insist upon my own opinions. If any opinions I have formed hitherto are shown to be wrong, I shall be very glad to change them. What I want is the facts. I am just as anxious as the Alaskans to see the coal opened and the natural resources utilized. It is not good sense or good morals to tie up resources which are needed for immedate consumption. Contrary to the general opinion, the conservation men are not responsible for tying up the resources of Alaska. Since Mr. Roosevelt, while President, sent his first message urging development, in 1906, we have been trying to get Alaska opened under conditions fair to all the people. But we do not believe that development should necessarily mean monopoly.

"The people of the whole United States have become immensely interested in Alaska. They believe that certain questions here are not Alaskan questions alone, but national ones as well. The great interest shown by the people of the United States in Alaska will unquestionably result in promoting the immediate development of the country, and call national attention to the resources and advantages of Alaska. Senator Poindexter and I are anxious to meet the pioneers, the business men, the professional men, and above all the miners and prospectors, who have had practical experience and therefore are best entitled to give advice. One reason why the people of the United States are sensitive about monopoly in Alaska is that they have suffered so much from monopoly at home and are having so hard a time to fight it. They have been through the mill themselves, and are anxious that matters should be taken in hand in time in this new country before the evils against which we are struggling outside are fully fastened on the people."

Mr. Pinchot and party visited the Matanuska and Bering River coalfields and met many of the men concerned with the development of Alaska who are prominent in business circles.

Discussion

Readers of the Mining and Scientific Press are invited to use this department for the discussion of technical and other matters pertaining to mining and metallurgy. The Editor welcomes the expression of views contrary to his own, believing that careful criticism is more valuable than casual compliment. Insertion of any contribution is determined by its probable interest to the readers of this journal.

Porcupine Swastika Mining Co.

The Editor:

Sir—My attention has been called to a statement in the publicity section of the Swastika number of *The Mining Investor*, referring to me as having examined the claims of the Porcupine Swastika Mining Co., Ltd., and reported favorably upon them; also referring to me as the managing director of that company. I write to say that the statement that I have reported favorably upon the claims of the company is contrary to the fact; and I am not and have not, at any time, been managing director, or otherwise officially associated with the company, or a shareholder therein, or otherwise interested in the stock of the company. If further reference is made to me in any of these connections, I shall be compelled to place the matter in the hands of my legal advisor, and take such proceedings against parties responsible therefor as may be necessary to protect my interest.

R. B. Lamb.

Toronto, September 11.

A Case for the Stamp-Mill

The Editor:

Sir—In the *Mining and Scientific Press* of May 6, Algernon Del Mar, though partial to his old friend, the 5-stamp battery, does not by his argument approve of the 5-stamp single-discharge mortar. He is correct in that respect, but I cannot agree with him that a 5-stamp double-discharge mortar will crush as much ore as five 1-stamp mortars. There is some truth in the argument that the screen area in the single-unit battery is in excess of crushing capacity, and it seems to me feasible that 3 stamps suitably arranged with triple or quadruple discharge may crush equally as well as the one-unit stamp, but with a 5-stamp double-discharge mortar I do not see how the splash from the side of the stamps can touch the discharge screens.

In all newly-designed mills on the Witwatersrand the stamp-battery is looked upon as a coarse crushing unit, and there are practically no screen troubles when using a 9-mesh screen, aperture 0.27 in. The screens have a life of about 30 days. With single-unit stamps there would, of course, be a feeder for each stamp, as against one feeder for the 5-stamp double-discharge, as advocated by Mr. Del Mar. Feeders of the present-day type are no trouble whatever, and the difficulties of feeding ore when a 'bit sticky' to light stamps with fine meshing, disappear entirely with heavy stamps and coarse meshing, it being a matter of little consequence whether the ore is wet or dry.

On one mine here four Nissen stamps of 2000 lb. weight are running side by side with stamps of the same weight with single discharge. The stamp duty for the former is, I believe, 23 tons, against 15 tons for the latter. The screen used is 9 mesh.

G. A. Robertson.

Germiston, Transvaal, July 25.

Investing Without Investigation

The Editor:

Sir—I have noted that during the past year progress of a marked character has been made in the effort to suppress 'wild cat' mining, and now that the Federal authorities have taken an active part in exposing and putting this class of enterprise 'out of business' it seems that legitimate industry will soon take its place in the confidence of the public. The press having taken up the exposure of certain well known promotion houses, the general public has become quite familiar with the methods used to defraud, and will hereafter, no doubt, be more cautious when investing; however, there still remains a class of mining promotion with which I have become familiar during the past three years, and which I consider more dangerous than the well known 'wild-cat' companies, for these appear in the guise of respectability. Unfortunately, no action can be taken against them, for they are clearly within the law, and yet their influence destroys confidence. Usually the companies are in the hands of well known business or professional men, who, though honest, and possibly experts in their respective lines, know nothing of mining and are absolutely incompetent to handle such an enterprise.

Generally speaking, this class of mining companies (unlike the 'wild cat' which depends upon a vigorous advertising campaign for securing funds) depends chiefly on securing its money, not only from the officers but from their friends and their friends' friends. Their operations are limited, and when failure ultimately overtakes them, the matter rarely, if ever, becomes public, consequently the average investor is not aware of the pitfall that awaits him. When the property comes into the officers' hands, they immediately read up and soon learn such common terms as dip, strike, drift, shaft, winze, oxidized and sulphide ore, and, above all, true fissure vein; the latter they use constantly, and with a few other terms a profound impression is made on their friends' minds and upon assurance of great success they invest.

The officers themselves are confident of a success; usually for no other reason than that one or more of their number has been to the property and gone over it thoroughly—probably with a prospector who naturally will boom it, if for no other reason than that it might help him to sell his claims or because he might get a job. The thought of an engineer is foreign to their minds. They *know* the mine is good and the few hundred dollars for an engineer's opinion would be wasted, never thinking that in the end it would possibly save them thousands. Their own money and their friends' money goes into the prospect in sums usually limited to a few hundred dollars at a time; they do not realize and cannot be convinced that to open and develop a mine is at best a large undertaking and should be in the hands of experienced men, or that sums limited to a few hundred dollars a month, will not (even if judiciously expended) make a mine within a reasonable time. The consequence of such ignorance is that those who have invested soon become dissatisfied, and the officers must seek funds from others than their friends. This they rarely do, but generally they raise enough among themselves to continue a little longer. In the end they too become discouraged and the mine or prospect is abandoned. From then on all mines are censured and the one in which they placed their money particularly.

Each individual investor in a mining company that has failed has only himself to blame for not investigating, yet such men continue to deride the industry at large, and many promotions of exceptional merit cannot raise sufficient capital to make them successful. There is a certain element of risk in any enterprise, and should a mine that has stood rigid investigation be a failure, it is well to remember that everything cannot always succeed.

There is only one remedy for the evil here discussed, and that is to impress upon the investor the necessity for investigating not only the mine, but the ability of the officers to make it a success, and not to invest because he knows an officer to be honest; unfortunately, honesty, though a great factor, cannot take the place of knowledge. With this class of mining enterprise out of the field, the industry would be looked upon with greater favor, and I sincerely hope everyone connected with mining will, whenever the opportunity affords, try to remedy a condition which can only reflect discredit to their profession.

F. A. Crampton.

San Francisco, August 31.

By far the greater part of the gold found in placer mines occurs as dust. It is remarkable that no great masses of gold have ever been found, the largest being small in comparison to those of copper, iron, and silver.

Concentrates

Most of these are in reply to questions received by mail. Our readers are invited to ask questions and give information dealing with the practice of mining, milling, and smelting.

PETROLEUM production is quoted in the United States in barrels, in Russia in poods, and elsewhere usually in long tons, 2240 lb. It is convenient to remember that 7 U. S. barrels equal one ton, and that 62 poods equal one ton, or 9 poods one barrel.

SULPHURIC ACID is used for such a variety of purposes that it has been said that the amount of its consumption is an index of the state of industrial advancement of a country. As its cost is low and transportation difficult it is usually produced near the place of consumption.

BLASTING mats are woven mats of rope which are spread on the ground above the bore-holes when blasting is done where flying pieces of rock will be dangerous. If heavy charges of explosives are used it is the custom to place logs or railroad ties directly over the bore-holes, and the blasting mats on top of these.

ENARGITE is a sulphide of arsenic and copper and is a black, brittle mineral of metallic lustre, usually columnar or granular in structure. Before the blowpipe it yields white fumes with a garlic odor, and a button of copper. Enargite is frequently associated with other copper minerals, and occurs mainly in the mountains of Chile and Peru, but is found at Butte and in other parts of the United States.

HALITE is the mineralogical name of rock salt, which occurs with rocks of all ages in beds of great thickness that have been formed by the gradual and complete evaporation of bodies of water into which the salt has been brought in small increments by inflowing streams. These exist in all parts of the world, but those in Poland, Austria, and Germany are most noted because of their size and the large scale upon which they are worked.

PENCIL MANUFACTURERS have been buying old cedar rails and cedar boards from the old barns of the farmers for the reason that such wood, having been exposed for many years to the elements, is in far better condition than new cedar. The new cedar carries a large amount of resinous matter and it is difficult and expensive to get rid of this. When not thoroughly eliminated, it tends to warp the pencils and to ooze out, marring if not destroying the finish.

DRYING pulp and slime samples is accomplished simply and effectively at the laboratory of the Mines Company of America, at La Colorado, by an unusual device. Instead of drying the samples by heat, the moisture is extracted by a vacuum process employing the principle of the vacuum-filter. A canvas is stretched across the bottom of a small sample-drying pan, and the vacuum applied at the bottom by a hand-pump. The pans are 6 in. across and 2 in. deep.

MEAN sea-level, is the level that the sea would assume if the influence of tides and winds were eliminated. This level is not the elevation determined from the mean of the highest and lowest tides, nor is it the half sum of the mean of all the high tides and the mean of all the low tides, which is called the high-tide level. Mean sea-level is the average height of the water, all stages of the tide being considered. These elevations have been determined by the United States Geological Survey in connection with its topographic surveying.

TELLURIDES of gold and silver are of much more widespread occurrence than is generally realized. The various tellurides of gold and silver were first identified in Hungary and later were found in small quantities in the Colorado districts north of Denver and in the veins of the Mother Lode in California. They were not of much economic importance, except for the difficulty of milling ores containing them, until Kalgoorlie and Cripple Creek were discovered almost simultaneously. These two districts have each produced large quantities of gold from telluride ores. In spite of this the nature of the telluride minerals is not thoroughly understood, and there is much ground for supposing that they are simply alloys of gold, silver, and tellurium in variable proportions.

RADIUM commands a price at present of $80,000 per gram (approximately 0.035 oz.). The total quantity so far produced is 3½ grams, and 'banks' have been established in Paris and London which loan small quantities at the rate of $200 per day. Radium is chiefly produced from the uranium ore at Joachimsthal in Bohemia, and as large quantities of this must be handled to obtain small quantities of radium, the cost of the latter is largely dependent upon the market for uranium. Ores containing radium are known to occur in many other places, but have not been made the basis of an industry as yet, nor have the waters of the many springs that exhibit radium emanations as yet been utilized.

THE principal use of fuller's earth in this country is in bleaching, clarifying, or filtering of fats, greases, and oils. The common practice with mineral oils is to dry the earth carefully after it has been finely ground, and run it into long cylinders, through which the crude black mineral oils are allowed to percolate very slowly. As a result, the oil that first comes out is perfectly white and much thinner than that which follows. The oil is allowed to continue percolating through the earth until the color reaches a certain maximum shade. Then the fuller's earth itself is clarified by a steaming process and used over again. With vegetable oils, however, the process is radically different. The oil is heated beyond the boiling point of water in large tanks, from 5 to 10% of its weight of fuller's earth is added, and the mixture is vigorously stirred and then filtered off through bag filters. The coloring matter remains with the earth, the filtered oil being of a very pale straw color. American fuller's earths are better adapted than the English earths for use on mineral oils, but the English earths are superior for the treatment of fats and vegetable oils. In clarifying vegetable and animal fats with American earths a more or less disagreeable taste is left, but the reason for this has never been determined.

ZINC DUST is a by-product of spelter making. The zinc vapors escaping from the muffles during the reduction of the ore are never completely condensed in the receiver to liquid zinc, but a considerable portion is caught in the form of metallic dust by special collectors connected as closely as possible with the receivers. In order to avoid the loss of any zinc vapors that are not precipitated in these collectors, the latter are further connected with collecting channels and similar appliances. The proportion of the zinc-dust recovery to the spelter production depends on the zinc content of the furnace charge, as well as on the temperature of the distilling furnaces. With a rich charge and a hot furnace, which means a high tension of the zinc vapors, the zinc-dust recovery may reach from 10 to 15% of the spelter production. The best quality of zinc dust, so far as the percentage of the metal content is concerned, is derived from the special collectors, because the stuff precipitated in them is least exposed to the oxidizing influence of the air. This dust is composed of from 88 to 93% metallic Zn, and contains from 6 to 10% ZnO, as well as small quantities of Pb, Cd, As, and Sb. The initial dust, a product which is formed three or four hours after the distilling process has been started, possesses a comparatively high percentage of oxide of zinc, but it also holds nearly the whole cadmium content of the furnace charge. It is, therefore, used by preference for the production of the latter metal. Merchantable zinc dust must contain at least 90% of metallic zinc.

LONDON

Coal in Ireland.—Sir William Ramsay's Lucubrations on the Future of Great Britain.—Lead and Zinc Markets.—New Developments at Broken Hill

A few weeks ago I referred to the reported revival of placer gold mining in the north of Scotland and described how this event recurs with a certain amount of regularity whenever the newspapers are short of more interesting matter. This week prominence has been given to a similar event in connection with coal in Ireland. Ireland is a distressful country, and its bad luck started ages ago, geologically. The middle part of the island is a wide and flat plain, having Carboniferous limestone as the basal rock, with a covering of peat and alluvium. At one time it was overlain by coal measures, but these have been almost entirely removed by erosion and only a few patches remain. One of these spots is in Kilkenny, another is at the boundary of Kerry, Limerick, and Cork, while in the northern part of the island some small isolated spots remain in Tyrone and Leitrim. Some of these are worked in a desultory and restricted way. Railway communication is poor and transport is confined to carts. At the present time attempts are being made to exploit the deposits at Castlecomer in Kilkenny, where it is reported that a good seam of steam coal can be worked on a scale of 400 tons per day, and a railway through the property is to be built connecting the towns of Kilkenney and Athy. All these reports have to be taken with the proverbial grain of salt, and people who know the district are skeptical as to the existence of the seam. It is, of course, perfectly well known that there are seams of anthracite of limited extent and varying thickness, but that is not the same as an extensive bed of steam coal. I am afraid that the scheme will fizzle out, just like so many that are trotted forward during the summer holidays.

While writing about coal, it is of interest to give some comments on Sir William Ramsay's gloomy prophesy of ruin and starvation that is to overtake the British nation 175 years hence when the coal resources of the British Islands are to suddenly become exhausted. There never was so unpractical a scientist as Sir William Ramsay or one so prepared to offer opinions on subjects with which he is unfamiliar. He starts with the official figures of a Royal Commission which stated in 1906 that at depths not exceeding 4000 ft. there were known seams that could be worked under present circumstances containing 100,000 million tons. The present consumption is roughly 250 million tons per annum, and if the consumption did not increase this would last 400 years. But Sir William figures that the consumption will gradually increase until in the year 2050 it will be 770 million. It may legitimately be asked whether this supposition of increase is logical. However, I will let that pass. If he takes it for granted that the consumption of coal is to increase, why not also admit that inventors will continue to improve the mechanical advantages at our command? The history of the advance in mechanical achievements at our collieries shows immense strides during the past twenty years, and there is every reason to believe that within the next twenty years work will be [illegible] power [illegible]. Then what about the [illegible]? Certainly, England has [illegible] water power, but why not stretch our imagination and see visions of [illegible] cables over the North Sea from Norway and Sweden. And what about oil? And [illegible] can be obtained for coal, surely the country will [illegible] and leave a large [illegible] food, work, and wages. The [illegible] exhaustion of the fuel resources would be seen in advance, and over a series of years the [illegible] would gradually change. Times would change, and people with them. Sir William was also inaccurate in his details. His calculation as to the relative power of a man and a horse deduced from his own observation of an Eastern potter's capabilities contained a mistake in multiplication of which a first year's student in applied mechanics would be ashamed. Then again, his claim that the steam turbine reduces the coal consumption per horse-power hour from 4 or 5 lb. to 1 or 1½ lb. was an absurd travesty of the real facts, while his reference to the Mond gas plant as a type of efficient application of the calorific power of fuel was quite inappropriate because it happens to be the least efficient of all on the market.

The lead and zinc markets are at present attracting general attention in London, for it is admitted that we are in for another period of high prices. Consequently the shares in Broken Hill mines have been pretty firm recently. The most important event is the reopening of the Broken Hill Proprietary. For the last two years this company has lived on its smelting works and on custom ores, and no great profit has been made. But the company is now approaching a new lease of life, for the zinc distilling furnaces are practically complete. The difficulty of obtaining suitable clay for the retorts has been solved, and the local workmen have been properly instructed by a European expert. There will be no difficulty in marketing the zinc without the aid of the European ring, and any obstacle that there may be in this direction will be insignificant compared with the difficulties fifteen or more years ago when the company took the sale of lead into its own hands. An even more important step to be taken is the starting of iron manufacture and the utilization of the great deposit of iron ore at Iron Knob. Hitherto this ore has been used solely as flux in lead smelting, but the time appears to have arrived when the company is to embark on iron smelting. Nothing official has been divulged as to this policy, though there can hardly be any doubt as to the correctness of my information. The manager, G. D. Delprat, is about to pay a visit to Europe and elsewhere, and the study of iron metallurgy will undoubtedly be one of his occupations during his tour.

JOHANNESBURG, TRANSVAAL

Record Output for July.—Brakpan Record.—Lack of Labor and Power.—Individual Records.

Record monthly outputs of gold have been making their appearance more frequently of late, but that for July possesses all the more significance because it is the first time in the history of the gold-mining industry of the Transvaal when the monthly output has exceeded three millions sterling in value. In fact, the output for July constitutes many other records. The total output for the Transvaal was 709,258 oz., valued at £3,012,738, but of this large value the Rand is credited with no less than £2,887,953, leaving for the outside districts only £124,785. It is clear that it will only need another such improvement to enable the Rand to claim a three million sterling output all to itself, and were it not for the scarcity of unskilled labor such a high standard of production would have been reached long ago on the Rand. Nevertheless, with so many stamps at Randfontein, City Deep, and elsewhere standing idle for lack of labor and power, it cannot be many months now before the Rand output alone is valued at three millions sterling. Seeing that July was a long month, the total ought to have been even better, for more than a third of the mines recorded decreased outputs when under ordinary circumstances they ought to have recorded improvements. Brakpan was perhaps the most notable individual producer, because this was its first declaration, recovering in June £18,087 from 18,133 tons treated. In July, however, there was a marked improvement, for from 25,400 tons treated, a recovery of 9594 oz. was obtained; equaling 7.5 dwt. per ton. This was even a better recovery than the City Deep, which only managed to show a recovery for the month of 7 dwt. per ton. The classification of the July output was as follows: mill £1,849,574, sand £1,110,369, and miscellaneous sources £52,795. Another striking feature of this record output was the fact that it was obtained in the face of diminishing labor supply, as during the month there were only 181,582 natives employed on the average, as against 186,940 in June, 190,392 in May, and 194,328 in April, when the record high-water mark was reached. The average daily yield on the Rand was also a record, having increased from £93,028 for June to £95,160 for July. Of course, there were more stamps at work, both on the Rand and in the outside districts, the total number being 10,177, of which 9580 were on the Rand and 597 in the outside districts. Tube mills increased in number from 219 to 223. The following are the twelve leading producers, which succeeded in producing more than half the total Rand output:

	Tons Milled.	Oz.	Value.
East Rand Prop. Mines ..	202,400	60,000	£254,864
Crown Mines	143,000	59,024	250,718
Randfontein Estate	200,534	56,955	241,929
Robinson Mine	47,100	25,028	106,312
Geldenhuis Estate	68,970	23,375	99,291
Simmer & Jack	75,500	22,409	95,088
Mourse Mines	54,200	19,373	82,185
Rose Deep	59,400	19,276	81,879
Village Main	41,200	18,178	77,215
Robinson Deep	49,800	17,507	74,365
New Modderfontein	47,700	17,390	73,868
Ferreira Deep	30,850	16.246	69,009

BUTTE, MONTANA

Butte & Superior Mill.—Progress at Raven.—Smelter Additions at East Butte.—Moulton Closed.—Legal Decisions.—Shaft Sinking at Black Rock.

At the Butte & Superior excavations for the new concentrator are being made, but none of the material has yet arrived. The machinery to be used will practically all be taken from the Basin Reduction Works and will be removed in such a way as not to interfere materially with the treatment of ore. The lease on the Basin Works expires early in the summer of next year, and it is expected that the 500-ton concentrator will be ready for use early next spring and will be so constructed that units can be added at any time. The Butte & Superior company is at present shipping 400 tons per day, and this amount could easily be increased, as a very large amount of ore has been blocked out. The Butte & Superior company is said to be earning around $30,000 per month net.

Little work is being done in the Raven mine except by lessees. Nothing can be done on the lower levels until the water is removed from the 1300-ft. level, but the lessees working on the upper levels are doing a lot of development work and are getting out some high-grade silver ore.

1300-ft. level, but the lessees working on the upper levels are doing a lot of development work and are getting out some high-grade silver ore.

The East Butte company is developing orebodies on the 1000-ft. level said to carry 7% copper. Up to recently this level was never explored, but it appears equally as rich as on the 800, 1300, and 1400-ft. levels, on which a large amount of ore is being blocked out. The company is maintaining a production of about 1,000,000 lb. per month from its smelter, and no effort will be made to increase this output until market conditions considerably improve. All the ore treated at the company smelter practically comes from the East Butte mines, the only custom copper ore being received coming from the Butte-Alex Scott. A third blast-furnace is being built, but this will not be completed before next spring, and by that time it is hoped that the market conditions will have so far improved that production can be increased enough for putting into commission the new furnace. A dust-chamber, 300 ft. long and 50 ft. wide, will be completed about the first of the year. This contains three flues and will save all the flue-dust which is now lost through the stacks, making quite a saving in the cost of production.

A shipment of 50 tons of silver ore from the Moulton mine, owned by W. A. Clark, was sent to Salt Lake for experimental purposes, but after a very extensive series of tests, the conclusion has been reached that the ore can not be handled at a profit, and the mine has been closed.

An attempt was made to compel the North Butte Mining Co. to pay taxes on new property and improvements in addition to the tax on the net proceeds of the mine, amounting to over $20,000. The company took the matter into the courts and won its contention. The Barnes-King Co. has had a judgment of $5000 recorded against it in an action for damages through a man falling down the shaft. The man who sustained the injury sued for $30,000.

The cross-cutting from the Black Rock mine of the Butte & Superior at a depth of 1300 ft. under the Pilot Butte shaft will be completed in about another two weeks, which is considered record-breaking time. A crew will then start raising to meet the shaft sinking party, and before the first of the year, Mr. Sheehan, the superintendent, says, the two parties will meet. No effort has yet been made to definitely determine whether the rich body of copper ore found when running the cross-cut is in Elm Orlu or Pilot ground.

SILVERTON, COLORADO

Sound Democrat Leased.—Consolidated Eureka Finds Ore.—Iowa Tiger Again in Good Ore.—Silver Lake Milling.—Gold King Lease.—Hercules Resumes. Silver Ledge Shows Improved Saving.

The month of August was the most active of the present season, and a number of examinations were made, some of which may lead to active operations with the beginning of next season. The Sound Democrat mine, formerly leased to Messrs. Smith and Terry, is now controlled, under bond and lease, by Messrs. Ross and Nickels, who announce that milling will be resumed at an early date. The mill has been repaired and the mine is being cleaned up and placed in shape for active operation. The Vermillion mill is crushing 75 tons daily and shipping two cars of zinc and one car of lead concentrate per week. The Bagley is still inactive and will probably remain so until the spring of 1912, when a mill will be built. The Columbus is also idle, except for one shift of two men, who are driving on a new vein discovered in the lower Laura tunnel. This vein is 14 ft. wide, but is low grade. The lessees hope to find better ore with depth. The Consolidated Eureka company recently cut a vein in the Domingo adit, which carries good ore, but is too small for profitable mining. The company is now driving on the vein.

The Sunnyside continues its steady production and there is little new of note at the property. The water supply for the new hydro-electric plant has failed, and the company has been compelled to revert to the San Juan Water & Power Co. for electric power. The mines of Minnie gulch are all idle, except for a small leasing company operating a part of the Esmeralda mine. In Maggie gulch, the Intersection Leasing Co. is operating the Intersection mine, but without very favorable results. The Danforth Leasing Co. is operating the Little Maud mine under bond and lease, the work being confined entirely to development. The Iowa Tiger Leasing Co. is again in good ore in the Iowa mine and is milling 100 tons per day and shipping 25 tons of 40% lead concentrate. The Silver Lake, operated under lease by the American Smelting & Refining Co., is milling from 40 to 50 tons per day. The ore is rather low grade. but it is reported that some high-grade ore has been found and that a shipment will be made soon. Messrs. Mears and Slattery have applied for a lease on the Gold King mine. The stockholders have approved the application, but as the mine is in litigation between the stock and bondholders, the approval of the bondholders is necessary, and this has not yet been obtained. The Hercules is again operating, under the management of Thomas Kane. Development work is being pushed, and milling will be resumed as soon as the ore reserves warrant. Lead ore of good grade has been found on the lowest level.

Denver capitalists are investigating the Idaho with a view to purchasing, and it is probable that the mine will be examined in their interest. The Silver Ledge is milling an average of 125 tons per day, and the management reports a saving of 85% of the lead and 65% of the zinc in the crude, a much better result than has heretofore been attained at that property. The mine is in excellent condition and the ore reserve is well ahead of production. The San Antonio is idle except for a few men on assessments. The Congress lessees are driving in virgin territory, but without results as yet. The American Mining Congress has organized a Silverton branch, and twenty-five applications for membership have been received. The Congress is endeavoring to organize the mining men of the State in an effort to secure State and National appropriations for mining investigations.

TORONTO, CANADA

Resumption of Construction at Porcupine.—Capitalization of Dome Increased. — New Goldfield. — Semi-annual Statement of the Mineral Output.—Crown Reserve.

Nearly all the Porcupine mines which suffered by the fire in July are again in operation and preparing for an active winter's work, which will be carried on with fewer difficulties than last year on account of the improvement in the roads. Heavy teaming will now be practicable without waiting for the setting in of the cold weather. Building is going forward with great activity, though complaints are made as to the difficulty of getting supplies of material as required. In Porcupine some 400 buildings have gone up and operations are likely to be brisk as long as the open season lasts. It is estimated that about 2000 men are now employed in connection with mining and 1000 in building and road-making.

The West Dome has installed three boilers of 150-hp. capacity and a 20-hp. hoist, and is putting in machinery in the power-house. The damage caused by the fire at the Preston East Dome has been repaired and the shafts are being pumped out for the resumption of operations. The capitalization of the Dome has been increased from $2,500,000 to $3,500,000, the new stock being taken up by present shareholders in the ratio of two new shares to every five already held. The Reciprocity Mines, Ltd., recently organized with a capital of $1,000,000, has taken over the McKenzie Veteran claim of 160 acres some distance to the north of the Rea.

J. B. Tyrrell, in a special report on the Lucky Cross, Swastika district, states that gold is visible in a number of quartz veins uncovered on the surface and recommends the sinking of a shaft on vein No. 16. A plant has been ordered for the purpose. The Sutherland claims in Bristol Township have been purchased by a Duluth syndicate for about $300,000. At the Thompson claim in Bristol, about a mile south of the first discovery in the district, a 6-in. quartz vein carrying free gold has been found.

The new goldfield at West Shining Tree is attracting much attention, and seems likely to prove a second Porcupine. Prospectors are pouring in and a large area in the townships of Churchill, Asquith, Fawcett, and McMurchy has been staked. The first big deal is announced, the Gosselin property, on which the original find was made, having been sold to Mackenzie & Mann of Toronto for a sum said to be $300,000. The Dome interests are represented in the camp and are reported to be negotiating for claims. The field will shortly be easier of access, as the Canadian Northern railway is building an extension which will run within 15 miles of the camp. Numerous finds of free gold have lately been reported from outlying townships around Porcupine, including Cody, Thomas, and Timmins.

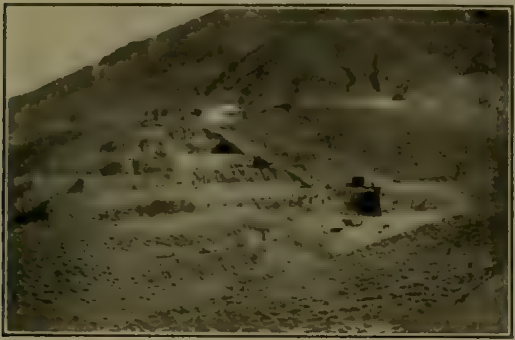
The statement of the output of the metalliferous mines and works of Ontario issued by the Ontario Bureau of Mines for the six months ended June 30, shows a substantial increase in the production of silver. The total output from all sources was 15,231,969 oz., valued at $7,644,200, being an increase of 2,417,142 oz., in quantity and 1,376,670 in value, as compared with the first six months of 1910. Of the current year's product the great bulk came from Cobalt, the shipments from Gowganda and South Lorrain being only 430,540 oz. Shipments from Cobalt have dropped 20% owing to the increased tonnage in the form of concentrate. A new item in the list is furnished by the by-products of the separation and refining processes carried on at Cobalt, namely, cobalt and nickel oxides, produced to the amount of 219,584 lb., of the value of $54,876. The yield of gold continues small, as was to be expected, considering the delay in Porcupine production caused by the fire. The output was only 2276 oz., of the value of $42,320. The Crown Reserve has found its No. 14 vein on the 150-ft. level in the Keewatin formation. The vein at this depth is 3 in. wide and runs 5000 oz. per ton. This company has declared its regular quarterly dividend of 2% and the monthly bonus of 3%, and when these are paid will have returned to the shareholders a total amount of $3,449,181, being over double the capitalization. The new shaft on the Gould Consolidated is down 88 ft. and another vein has been cut. Native silver is showing in the wall rock. The Beaver has substantially improved its position. A statement for the quarter ended August 31 shows shipments valued at $133,500. The company has $59,960 cash in hand and approximately $135,000 to be received from the smelters, being an increase of $68,718 in liquid assets over the previous quarter. The Buffalo has declared the regular quarterly dividend of 5 per cent.

NEW YORK

Reaction Against Wall Street.—Corner in Porcupine Central.—Nevada Hills.—The Copper Market.—Inspiration Ore Reserve.—Ore Treatment at Nipissing Mines.—Increase of Capital of Dome.

The high records shown on the tape during the wave of liquidation that for the past month has been and is still rolling in upon the stock market, have been 'high for the day' as against new 'low levels for the year,' recessions which have likewise been matters of almost daily record. The tensity of the situation is apparent. The occasional ebbs in the tide of selling orders have been marked by almost complete stagnation, and the ever-present hope that the market might be about to turn, has from time to time taken definite form, only to find itself overwhelmed and the market again helplessly adrift. What is to be the end is a question. Rumors of financial trouble here and there in high places are afloat in the street, but up to the present moment no failures of importance have been chronicled. As a matter of fact, Wall Street is paying a just penalty for the abuse of a longsuffering and confiding public. For more than one generation Wall Street had a following that perpetually maintained a reverent attitude and asked no questions, but paid, paid, paid. Now, the same Wall Street is a part of a painful practical exhibition of the wonderful working of the law of compensation. Having, after some years of experiment, taken proper measure of some so-called high financiers, and having had a rude but salutary awakening, the public, which for so long furnished the power for Wall Street's speculative machine, has resolutely turned its back, and now, when its support is wanted, is gaily buying a new automobile or a new set of tires for the old one. This determination is probably attained by reasoning similar to that of the man who, importuned by a beggar for the price of a drink, said that if anyone was to spend the money for whisky, he would do it himself. If Wall Street could regain any definite degree of public confidence, the present acute situation would be quickly relieved.

In the mining market the principal feature of the week was the engineering of a corner in Porcupine Central. For some months the usefulness of the outside market has been impaired by the tactics of traders who resolutely took the short side of the market on all new issues as they appeared, either ostensibly carrying the stock on margin for customers, or delaying deliveries to customers buying outright, in each case trusting to a decline in the market to either wipe out the margin trader or to allow the shares for actual delivery to be purchased at lower levels and correspondingly greater profit. These tactics absolutely prevented any distribution of shares in new enterprises, which is the chief function of any stock exchange, organized or open. When Porcupine Central was offered in the open market, there were many margin orders placed with the houses that accept this class of business. Execution of these orders around 70c. per share was reported, but, following the usual custom, no order was actually executed. A little later the stock began to move up, and, there being little or no real stock in the hands of the public, the house which offered the shares had no trouble in advancing the issue. The orders which had been placed on a margin basis were all taken up, the balance due tendered, and delivery demanded. The result was a squeezing of the house playing short in the manner outlined to the tune of some $200,000; and the hope is general that margin business in mining stocks, which is impossible on any legitimate basis, will no longer be carried on in the illegitimate manner which has heretofore prevailed, and which has done more than any other one factor to retard the growth of the New York mining market.



MILLSITE AND MILL CONSTRUCTION, NEVADA HILLS.

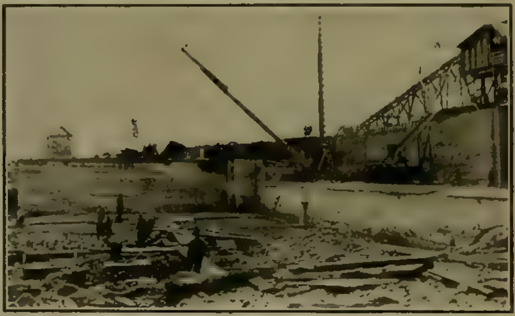
Next to this sensational coup in Porcupine Central, the movement in Nevada Hills has been the chief feature. There has been heavy liquidation of the shares, apparently coming from Salt Lake. Nevada Hills has always been fairly well held in the East; many holders went into the stock because of the Wingfield connection and because of the leadership which was held by Goldfield Consolidated as long as it was dealt in in the outside market. These holders have been anxious and insistent in their inquiries as to who is selling, and why. The resignation of W. H. Webber engendered a fear that he and his friends were getting out.

The copper metal market appears to have a long and difficult gauntlet to run. The decrease in accumulated stocks shown by the August figures was hardly posted where it could be pointed to as an argument for better prices, when the Franco-German war cloud began to assume threatening proportions, and as Germany has been a tremendous consumer for some time, not only was the effect of the improved technical position nullified, but a distinctly weaker tone was made manifest. Germany has been taking copper at such an abnormal rate that a reaction was in order in any event, but the copper market is in no position to withstand such a decrease in consumption as would be inevitable in the event of actual hostilities between France and Germany. The added production for next year is a vital factor. The 'porphyries' are the subject of many analyses, as these properties are so fully in command of the metal market. An illustration of the anomalous position in copper is contained in the estimated increase of production next year of 200,000,000 lb. and in the remarks of J. Parke Channing to the effect that:

"Owing to the exhaustion of the older mines, there soon will be a shortage in the world's supply of copper, unless, in the meantime, great orebodies are found. The basic condition of the mineral industry is that the world's supply of gold, copper, and lead is short, while there are ample supplies of iron, zinc, and silver already developed or known to exist."

It is reported that Greene Cananea is maintaining a copper cost of 9c. This is the best figure the company has ever made, and it is now possible only by reason of the complete reconstruction of the plant at heavy cost. Greene-Cananea is producing a little more than three and a half million pounds of copper monthly. On the present basis, improved conditions would be reflected in the market, if the company were not loaded down with an enormous capitalization. Inspiration Copper, which adjoins the Miami, while not so far along with its development as its neighbor, will undoubtedly reach the stage of initial production in 1912. The company's ore reserve is now estimated at 26,569,400 tons of developed and 81,000 tons of partly developed ore, and about 3,000,000 tons of lower-grade ore, giving a total of 29,453,100 tons containing an average of 39 lb. of copper per ton, or a total of 1,150,000,000 lb. of copper. The plant, which is to be erected under the supervision of C. H. Repath, is expected to produce between 40,000,000 and 50,000,000 lb. annually. Mr. Repath is in charge of some very important construction work, including the new smelter at Jerome for the United Verde and the additions to the smelting plant now being erected at Bisbee for the Calumet & Arizona. Mr. Repath was also one of the engineers in the construction of the International plant at Tooele, Utah.

J. R. Finlay's report upon the copper mines of the Lake district continues to set the New Englanders by the ears. Discussing the Superior mine, Mr. Finlay arrives at a present value of about $1,000,000, as against an appraisal by the Calumet & Hecla committee of $5,272,000. Mr. Finlay's popularity in Boston may be estimated as considerably less than nothing. New England's attitude toward the public in regard to Lake coppers has always been absurdly exclusive, and the jar which Mr. Finlay has given them is not at all liked.



PUTTING IN PRECIPITATION TANK FORMS, DOME MILL.

The Dome Mines Co., Ltd., is increasing its capitalization from $2,500,000 to $3,500,000. The additional $1,000,000 of stock is to be offered to shareholders at par, $10, in the proportion of two shares of new stock for each five shares held. The proceeds are to be utilized in the completion of the plant and in extension of the underground work. The public has very little line on the Dome. It has not been made a market offering, as was the case with Hollinger, though there has recently been a little trading in the stock around $40 per share on a basis of $10,000,000 for the property. The company is controlled by W. S. Edwards and his associates, who were the original owners, and the International Nickel people, and it has been practically run as a close corporation.

The Nipissing Mines Co. is now refining its high-grade ore at its new plant and making shipments of bullion. It is expected that the plant will be able to handle second-grade ores with slight modification. The company has a very large quantity of 30 to 40-oz. ore, from which it is now anticipated a much greater profit can be derived than under the old method of paying high treatment and shipping charges. A custom jigging-plant is to be erected on the Nipissing property to handle ores from all the surrounding shafts.

General Mining News

ALASKA

Copper River

Chitina news despatches state that F. A. Smith and John Delanders have found a vein of free-milling ore near mile 111. Two claims have been staked. The vein varies from four inches to four feet in width.

Juneau

An 18-inch vein of gold ore, in a phonolite and quartzite formation is reported to have been discovered in the Devil's Creek district by Wallace Erwin.

The Alaska Treadwell G. M. Co., in the month ended August 15, crushed 83,412 tons of ore, and saved 1530 tons of sulphide. The estimated value of the free gold obtained is $128,786, and of the sulphide is $102,525, making a total production of $231,311. The estimated realizable value of the production is $225,534. The operating expenses were $89,802, leaving a net operating profit of $135,732. Construction expenses during the month were $15,701. The development work done amounted to 805 feet.

Prince William Sound

Joe Stanton and Abe Bell are reported to have found tellurium at the head of Sheep creek. For several miles the creek runs through a box canyon and the country is difficult of access.

Norman Merchant, after returning to Valdez with associates from an inspection of the Klutina Lake district, states that as yet there have been no discoveries warranting the belief that gold is there in paying quantities.

Five claims on Shoup glacier, located by Dave Olson and said to be the richest discovered there, have been bonded to O. Roberts and Herbert Johnson, who are reported to be affiliated with Los Angeles capitalists in the deal. The price named is said to be $15,000.

An important discovery of ore is reported near the Silver Gem property in the Shoup bay district. It was made by M. L. McAllister and W. W. Harvey.

ARIZONA

Yavapai County

(Special Correspondence.)—The United Verde Extension Co. at Jerome closed down last week. The shut-down is said to be caused by the death of J. J. Fisher, who was a heavy stockholder and general manager for the company.

A contract has been let to Joe Peila to drive 70 ft. in the main adit of the Eureka property. This is a very promising prospect situated in the Cherry Creek district. This work will cut the main vein at a depth of more than 200 ft. The outcrop on the surface shows gold and there is evidence of copper at depth.

The oil excitement still rages in the Verde valley. The Verde Valley Oil Co. and the Pittsburg & Verde Oil Co. have been incorporated, and both propose to begin active exploration for oil very shortly. P. L. Griffin and D. V. Snowgoose of San Francisco are named as being interested in oil development in the valley.

Prescott, September 16.

CALIFORNIA

California fuel oil will be used by the Cordova Power Co., of Cordova, Alaska, and George C. Hazlett, manager of the power company, has contracted with the Copper River & Northwestern railroad for 1500 barrels. A pipeline is being laid at the plant so that oil can be piped from the steamer to the tank. The company expects to save $33\frac{1}{3}\%$ in operating cost, as at present it is paying $12.50 per ton for the poorest grade of steaming coal delivered at the power-house.

Mariposa County

(Special Correspondence.)—The Treasure Gold M. Co. at Hornitos is about to increase its 5-stamp mill to 10 stamps, and in the near future will change from gasoline to electric power. Specimens of ore have assayed $10 per ton. The vein varies from 6 in. to 6 ft. in width, and on the average is 3 ft. wide. The mine is near the old Washington mine, four miles from Mt. Gaines. The mine formerly was worked by open-cut, but under the present ownership in the last five months $14,000 worth of ore has been mined on the 150-ft. level.

Hornitos, September 16.

Nevada County

It is now asserted that the recent discoveries at the Golden Gate mine, near Grass Valley, were grossly exaggerated, and that the ore in question is of ordinary grade.

(Special Correspondence.)—The North Star Mines Co. has about 100 men employed at the Champion mines, the August disbursement for wages surpassing $6000. This is the largest force employed in the mines for years. The road from Deer Creek to the Providence mine is being placed in excellent condition. With the new electric pump the Providence shaft will be the principal pumping avenue, and it is understood that the Merrifield shaft will then be abandoned. The North Star company is gradually concentrating operations, resulting in more economic working charges. Vigorous developments are under way from the Champion shaft and nearby workings. With the completion of repairs to the ditches and flumes of the Northern Water & Power Co., the Gaston, Erie, Anchu, and other mines in the Graniteville district are enabled to resume milling. The Gaston company has been greatly hampered throughout the summer by lack of water and has been compelled to proceed slowly. The Erie mill recently started, after lying idle many months. Other properties also have been adversely affected by lack of water-power. It is expected to have the new Tightner 10-stamp mill completed by October 1. The delayed arrival of the 75-hp. motor may postpone the initial operation of the plant. A tramway has been completed from the mine to the mill. The compressor is operating three machine-drills.

It is rumored that Eastern capitalists are considering the bonding of the Rose Hill mine, at Grass Valley. An 860-ft. adit intersects two veins. The property is credited with a production of $175,000.

Nevada City, September 18.

Sierra County

Rich ore has been found in the Osceola quartz mine at Alleghany, according to Dan McGonigal, who is opening the old mine. The vein is believed to be a continuation of the Tightner.

Siskiyou County

(Special Correspondence.)—The Golden Eagle and New York mines, in the Indian Creek district, have passed into the hands of Eastern capitalists. Both properties have yielded rich ore in past years, although operated in a small way. The purchasers are represented by Frank J. Spare. R. S. Taylor, owner of the Homestake mine, Salmon River district, reports the extraction of considerable rich ore from the recently opened vein. About 50 lb. of bonanza was taken out last week, running several hundred dollars per ton in value. From 150 to 200 tons of high-grade quartz have been recently taken out. The vein is showing a width of over 2 ft., according to reports. The Siskiyou Syndicate recently built a 5-stamp mill at the Keating mine, Coffee Creek district, and the plant is operating on several hundred tons of ore, stored on the dumps. Extensive development is under way in the mine. The syndicate continues to block out high-grade ore in the Cub Bear mine. Arrangements have been made for the driving of a lower adit at the Big Cliff group. It is designed to intersect the big vein parallel to the main orebody, which shows an average width of 15 to 20 ft. The main orebody is of immense size, but the owners are devoting attention to the opening of the smaller vein, because of its superior richness. The Big Cliff is situated on South Russian creek. F. H. Osgood and H. B. Wintering are principal owners. A Huntington mill is being erected at the Foster mine, in the Six-Mile section. It is expected to commence production before the snow flies.

It is rumored that operations will shortly be resumed at the Black Bear group. Several placer-mining companies are preparing for the winter season. Flumes and ditches are being repaired, plants improved, and other arrangements completed for an active season.

Yreka, September 15.

YUBA COUNTY

Newspaper despatches report a discovery of a vein at the Red Ravine mine, near Dobbins, about 30 miles from Marysville, specimens of which assay from $847 to $50,000 per ton.

COLORADO

CLEAR CREEK COUNTY

(Special Correspondence.)—A body of ore 12 in. wide that runs 365 oz. silver and 1.36 oz. gold per ton has been uncovered on the sixth level west of the Little Mattie mine. Williams & Sherman are operating under lease. The Ouida mine on Ute creek has been taken over by W. H. Maxton, a representative of Ohio capitalists. The shaft is to be sunk 250 ft. A test run of the McKelvey mill is under way. A number of operators have sent in ore of a sulphide character to be treated. The inventor and builder claims to be able to save 90% of the gold content, but does not claim to save the by-products. The plant has a capacity of 50 tons per day, according to McKelvey. Work has been resumed on the Little Giant mine on Red Elephant mountain. A cross-cut has been started to intersect the 100-ft. level. J. A. Young is manager. Work on the Bonnie Briar property is going steadily forward. H. Nimmo is manager. During the month of August 161 cars of ore left the C. & S. depot, the average value of which was $15. This was an increase of 64 cars over the same month of the preceding year, as well as the largest during any August in 12 years.

IDAHO SPRINGS, COLORADO.

Idaho Springs, September 13.

(Special Correspondence.)—Work in the advance of the Homestake adit was put under way this week. The bore is in 538 ft. A. L. Stephens is manager. The Clyde Hill M. Co., with a capitalization of $400,000, has been incorporated. The company owns a group of seven lode mining claims at Camp Beshears, Lincoln mountain. W. S. Crumley is manager. David Kennedy has resumed work on the Brazil mine at Freeland. Regular shipments are going out from the Welsh property on Leavenworth mountain, the ore milling on an average $90 per ton in gold and silver. J. Fowler is manager. Franchini & Co., leasing on the fourth level of the Smuggler mine on Brown mountain, made a shipment of 20 tons of concentrate last week that brought a mill settlement of 352 oz. silver and 52% lead. The zinc product brought 75 oz. silver and 40% zinc.

Georgetown, September 12.

SAN JUAN COUNTY

Harry Hilderman, S. W. F. Anderson, and Lloyd C. Sheets have taken a bond and lease on the group of claims owned by T. J. Shea, J. H. Sutherlin, and S. W. F. Anderson, in Georgia gulch, Red Mountain district, adjoining the Kansas City group, state advices from Silverton. The claims include the Sunrise, Early Morn, My Kid, Hazel Kirk, and Last Find. A cross-cut 150 ft. long is being driven to connect with the Kansas City vein.

SAN MIGUEL COUNTY

(Special Correspondence.)—The Lake Superior Ophir M. Co., capitalized at $1,000,000, has been organized under the laws of Arizona, to take over the property of the Calumet Telluride M. Co. Stock will be exchanged equally for stock in the Calumet Telluride company. The main offices will be in Hancock and the mine offices at Ophir. The Calumet Telluride company owns 44 claims in Colorado.

Ophir, September 15.

IDAHO

IDAHO COUNTY

The Welch Tunnel G. M. Co. has been formed to intercept by cross-cutting the Black Pine and June Bug groups of claims bonded to the incorporators by J. H. Williams. A millsite has been located on the American river. R. Kemp Welch, manager of the Idaho-Champion mine, is consulting engineer and general manager for the new company, in which the principal stockholders are Philadelphia business men already interested in mines.

This is an active season. The Monarch property, about three miles from this camp, is in steady operation on a grade of ore which assays $15 per ton and yields 50% by amalgamation. The company has a 5-stamp mill in operation and plans to add 10 more stamps this season. A large crew of men is building a wagon-road from the mine to connect with the road to Edwardsburg.

The Eagle M. Co. is erecting a 10-ton capacity Tremain stamp-mill and a cyanide plant and will have them in operation in a few days. This property is situated at Edwardsburg in the centre of what is known as the Big Creek region of central Idaho. Through the lack of transportation this country has been held in the background for many years, but indications point to this camp soon having transportation.

SHOSHONE COUNTY

Beartop-Orofino M. Co., capitalized at $4,000,000, in 2,000,000 shares of a par value of $2, which was organized as a result of the consolidation of the Beartop and Orofino mines, near Murray, is the latest shipper in the Coeur d'Alene district. The Beartop already has produced ore of a value exceeding $70,000, while the Orofino is opened by an adit, with a drift of 470 ft. on the vein and a raise now 178 ft. in ore. George J. Kiehler, manager of the Beartop, who will have charge of the consolidated properties, is a member of the first board of directors, others being John Costello, Chicago; Robert Sheffels, Govan, Wash.; William Tracy, Galesburg, Ill.; Fritz Marschante, J. N. Thennes, and George Rohrer, Spokane.

H. F. Samuels, of Wallace, president of the Success M. Co., while in Spokane announced the payment of the third dividend of $15,000 at the rate of 1c. per share, making a total of $45,000 for this year. The property paid $45,000 in three dividends of $15,000 each in 1907, and prior to that time, when operated as the Granite, its profits amounted to $600,000. The mill on the property is being improved, and the output increased month by month. The net profit in August exceeded $10,000.

Reports from Kellogg state that one of the richest finds yet made in the Pine Creek district is credited to the Nabob mine. A 14-ft. vein of high-grade silver-lead concentrating ore was encountered in the 2000-ft. adit, which has been driven to strike the ore.

The Federal Mining & Smelting Co. paid its regular quarterly dividend of 1¾%, or $210,000, on its preferred stock on September 15. This makes a total of $630,000 paid so far this year. The dividends paid on preferred stock to date total $6,431,000. In addition to this there have been paid on the common stock dividends of $2,708,750. The grand total of dividends to date is $9,139,750.

KANSAS

CHEROKEE COUNTY

The Edgar Zinc Co., represented by J. P. Walker, has purchased the 250-ton dump of the North Empire Tailing Co. The dump had been held two years on account of low prices. It is rumored that the price was a little over $20,000.

MICHIGAN

HOUGHTON COUNTY

The shaft being sunk on the Osceola vein, now 200 ft. deep, has not reached commercial copper in appreciable quantities. Thirty feet of driving was done at the 100-ft. level, but no copper of favorable quality was found. No. 3 shaft has dropped to the thirty-seventh level and No. 4 to the thirty-fifth. The shafts soon will be connected on the thirty-fifth level, as at all levels above.

MONTANA

JEFFERSON COUNTY

Arrangements for the new financing of the Boston & Corbin Copper Co., one of the Amster companies, have been completed. Some $200,000 of bonds have been underwritten, the funds to be used in making a thorough examination and report upon the property, and, if conditions justify it, in the immediate erection of a small concentrator.

LINCOLN COUNTY

(Special Correspondence.)—J. W. Allen and Wm. Williams of this place are developing what promises to be one of the best gold mines in this district, for they have a large amount of ore in sight which is quite rich. The property is situated on Great Northern mountain, 25 miles south of Libby, where they have eight claims, and on these are ten veins of ore, all carrying gold. The owners expect to install a stamp-mill on the property within the next year.

The first of the automobile trucks to be used in hauling ore from the Snowshoe mine to the Libby Lumber Co.'s logging railroad, a distance of eight miles, has arrived.

Libby, September 16.

SILVERBOW COUNTY

The official report of the Anaconda Copper M. Co. shows that 22,500,000 lb. of copper was produced in August. In July the production was 21,052,000 lb. Of the production last month, the Washoe smelter produced 16,000,000 lb., while the Great Falls smelter produced the remainder. The Butte-Ballaklava company, after many months of idleness, has resumed operation. The High Ore mine will be ready to resume under the compressor system by October 1.

NEVADA

ELKO COUNTY

(Special Correspondence.)—What is said to be the best find ever made in the Gold Circle district was made recently in the Elko Prince, at a depth of 400 ft., and 800 ft. from the mouth of the adit. The vein is said to be a high-grade quartz, 3 to 5 ft. wide, heavily impregnated with wire gold. W. C. Savage of New York, principal owner, is on his way there. The company soon will start construction for a mill.

Elko, September 9.

ESMERALDA COUNTY

The Goldfield Con. M. Co. has started construction for a roasting plant with a capacity of 75 tons per day, in which the tailing will be roasted to extract the remaining metal. The tailing carries 20 to 30 oz. of gold per ton. The plant, which will be equipped with two 54-spindle Edwards duplex furnaces, furnished by the Stearns-Roger Mfg. Co. of Denver, will be built near the concentrator. The present treatment makes a recovery of about 95%. The new furnaces will do away with sending the tailing to the smelter. After concentration the tailing will be roasted, then sent to the tube-mills for regrinding, thence to the Pachuca tanks, and lastly to the Butters filters. The remaining pulp will go to the dump. It will be a practically 100% extraction.

(Special Correspondence.)—The net profit of the Goldfield Con. M. Co. for August, according to a preliminary estimate, is $630,000, with a total production of $850,000 and operating expenses amounting to $220,000. The tonnage of ore produced (30,580) was the largest for any month this year, but the gross value and net earnings were lower than for any other month excepting January and July.

Goldfield, September 19.

LYON COUNTY

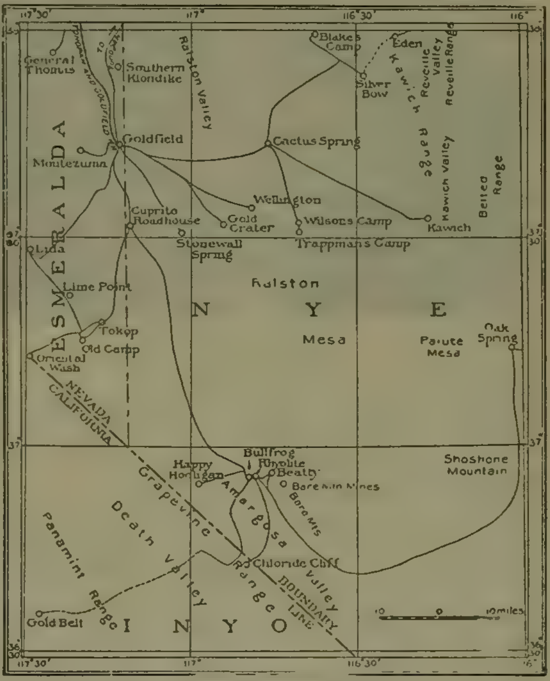
Reports for August from Silver City show a total of 1700 tons of ore treated at the stamp-mills and 1500 tons of tailing treated at the cyanide plants of that place.

Work on the Northern Light Copper Co.'s property will be resumed next month, as the result of action taken at a meeting at Yerington, when an option on 51% of the stock was granted to N. G. Douglass, Jr., of Los Angeles. Mr. Douglass agreed to spend $10,000 per year in development work and the minimum depth of work is to be 500 feet.

NYE COUNTY

Ore of exceptionally rich appearance has been discovered on the Diamond Bullfrog company. The completion of the Beatty mill in the near future will make profitable much milling-grade ore now on the dump.

The Nevada Leasing & Ore Purchasing Co. has been organized by W. S. Taylor to operate the proposed Beatty mill at Rhyolite and to assume the assets and pay the debts of the Nevada Ore Treating Co. A. E. Vinton, of Winnipeg, Canada, is one of the capitalists interested. The plant will be a custom mill, although it is to be operated in connection with the Murphy lease on the Diamond Bullfrog property.



PART OF NEVADA.

At the annual stockholders' meeting of the Montana-Tonopah M. Co., held at Salt Lake City, Utah, September 12, it was reported that the company last year treated 52,092 tons of ore, against 50,245 tons during the previous year. The net profit last year was $172,602, against $134,715 the year before. A. H. Lawry, mine superintendent, reported that there was a reduction in mining costs of 26.8c.

per ton over the previous year, and it also was reported that the mill costs had been reduced 64.1c., and that the mill had made an average metallic extraction of 90.7%. W. B. Alexander, treasurer and secretary, reported that dividends amounting to $120,000 had been paid during the year, leaving on hand $264,180. There is no indebtedness. To facilitate making complete reports for the fiscal year, which ends August 31, the time of the meeting was changed to the first Tuesday in October. On the board of directors Dudley Baldwin of Cleveland succeeds F. M. Kirk, and P. M. Braun succeeds J. W. Myers. The directors reelected last year's officers. Thomas K. Stevens was appointed agent for Utah, with an office at 204 Newhouse building, Salt Lake City.

White Pine County

The Ely Central Copper Co. has again commenced development of its property by churn-drill work.

S. M. Levy, president and general manager for the Ely Con. Copper Co., is quoted as saying that negotiations are under way for the development of the Ely Central property through the Zack shaft of the Ely Consolidated company. The 600-ft. level may be used. The affairs of the Ely Central company are in the hands of a committee which has decided to abandon the old Eureka shaft and to develop the property through neighboring groups.

The Pony Express Syndicate has made the final payment on a group of five claims at Hogum gulch, in the eastern part of the county. The claims formerly were owned by the Panguitch company. F. O. Morse is manager for the company.

(Special Correspondence.)—The coroner's jury, at the inquest into the deaths of Ed. Walsh, M. E. Foley, and Dan Drea, miners killed in the Giroux shaft fire on August 23, found the men came to their death from "the inhalation of fire, smoke, and gases from the Giroux shaft", and that the origin of the fire was unknown. The jury blamed the Giroux company for alleged failure to comply with the State mining laws. The Giroux shaft was again reopened September 15. The water was found to have risen to the 1134-ft. point. The pumps on the twelfth level have been 'drowned out' and the water will be removed by bailing.

Ely, September 17.

NEW MEXICO

Socorro County

Ore crushed at the Socorro mines in August amounted to 5100 tons, with a bullion product of 47,000 oz. Several tons of high-grade concentrate was shipped. The mill averaged 165 tons per day during the month. Rapid progress is being made in the erection of the new power-house. The new power-house of the Ernestine Mining Co. is nearing completion and will be ready to receive its equipment of high-compression oil engines, generator, and compressor, on delivery. The machinery will be shipped this month. The clean-up for the first 10-day period of September is now in progress. The week's ore treatment was 465 tons, with 50 sacks of concentrate. The new developments in the mine continue to show up well. A body of $12 ore has been opened on the 300-ft. level north, of the Deadwood mines. The mill handled 275 tons in the past week. A bullion product of 4000 oz. was made at the last clean-up. Twenty sacks of concentrate was produced during the week. A new rich discovery was recently made in the 150-ft. level east, of the Treasure Mining & Reduction Co. The vein is said to be 8 ft. wide and is a good average-grade milling ore. A large tonnage is broken in the mines. Sixty tons per day is now being treated.

Mogollon, September 15.

OREGON

Baker County

The North Pole mine at Bourne has been sold by Alexander Baring of London to capitalists represented by Albert Geiser, a mining man of Baker. The Eastern Oregon G. M. Co. is to be incorporated to operate the mine. No milling will be done this year, but development work will be pushed with a large force. Jim Duckworth, of Sumpter, this county, discovered the mine in 1887 and sold it to Mr. Baring for $10,000. Since the sale, under the management of Emil Melzer, the mine has produced several million dollars worth of ore, according to newspaper reports.

Benton County

(Special Correspondence.)—The School of Mines of the Oregon Agricultural College is collecting specimens of the geological and mineralogical deposits of the State for use in the school laboratory and museum. H. M. Parks, head of the school, accompanied by Arthur Swartley, his assistant, has just returned from one of a series of extended trips through the mining districts of the State for this purpose. It is hoped eventually to make up small exhibits for the use of the students in high schools in districts where geology and mining are of special interest.

Corvallis, September 17.

TEXAS

Brewster County

(Special Correspondence.)—The production of quicksilver in the Terlingua district for the present year will be considerably larger than that for 1910. Prospects are favorable for the construction of two or more new furnaces before the close of the year. New claims are being opened and good cinnabar ore is being developed. The official statistics of the production of the Terlingua district for 1910 show that the total output was 3320 flasks, valued at $154,413. Most of this quicksilver was produced by the Chisos M. Co. Its workings are down more than 400 ft., and at that depth the orebody has increased very much in size and richness. The 15-ton furnace is kept in constant operation. The Marfa and Mariposa mines were operated during the early part of 1910, but have since been closed down. It is reported that they are to be reopened soon and important improvements made with a view to again placing them on a good producing basis.

Good cinnabar ore has also been found in the mountains about fifty miles east of Terlingua and steps are soon to be taken for opening properties in that section. Now that the revolutionary troubles in the northern part of Mexico are over, American prospectors are crossing the Rio Grande below Terlingua and some good claims have been filed. It is reported that the cinnabar ores that characterize the Terlingua district are also found across the river in Mexico within a distance of thirty to forty miles. The agitation for the construction of a railroad into the Terlingua district has been revived. At present it is about ninety miles from the nearest railroad point to Terlingua. This makes the cost of hauling supplies into the camp very heavy.

Alpine, September 16.

UTAH

Salt Lake County

The new Bingham & Garfield railroad, operating between Bingham and Salt Lake to handle the traffic of the Utah Copper Co., has been placed in commission. There are two passenger trains daily in each direction.

Tooele County

Construction of the lead plant at the Tooele smelter will be resumed at once, after a delay to consider sintering methods. The Dwight-Lloyd process has been adopted, and an expert is now looking over the field. The stack and the foundations for the lead plant have been finished, and construction steel is arriving. Much lead ore is on hand and more is being mined. H. N. Thompson is superintendent.

Utah County

The annual report of the Mineral Flat M. Co. states that only sufficient work to retain title to the unpatented claims of the company has been done since June 1910, when operation was suspended, and two men are now doing individual assessment work and extending the south drift of the main adit. The only source of revenue at present is the company's power plant, which is being rented at $50 per month. The company during the year purchased at delinquent assessment sales 145,958 shares. All protests filed by adjoining companies and by the Government have been adjusted excepting one by the Government on five claims said to be on non-mineral land. The officers of the company were reëlected.

WASHINGTON

Ferry County

(Special Correspondence.)—The Ben Hur Leasing Co. has begun sinking the shaft below the 300-ft. level with three eight-hour shifts. The Imperator-Quilp company has received returns from the first shipment of ore to the Washoe sampler, at Butte, Montana, consisting of 135 tons, of a gross value of $7811. The net returns, after paying the freight and treatment charges, amounted to $6688.

At the Surprise mine the stope on the 600-ft. level is up about 40 ft. and is from 60 to 70 ft. long. The ore content has changed but little during the past week from that shipped during the previous week, assaying from $25 to $30 per ton. On the 200-ft. level the south cross-cut has intersected the vein about 60 ft., and, it is estimated, will have about 25 ft. farther to run to get under the original lessee's stope on the dip of the vein. On the 300-ft. level the north drift has about 45 ft. to run to get under the Wallek stope. The ore at the face of the drift has good shipping value. The south drift is in 80 ft. from the turn-sheet. The raise from near the end of that drift is in excellent shipping ore.

In the Insurgent mine the winze is about 500 ft. below the apex of the vein and in high-grade shipping ore.

Republic, September 18.

Stevens County

(Special Correspondence.)—The United Copper mine, in Chewelah district, has shipped about 6000 tons of ore in less than 18 months from development work. The ore is of gray copper and chalcopyrite, and contains gold and copper. The company has a favorable shipping contract with the Granby Con. M. S. & D. Company.

Chewelah, September 19.

CANADA

British Columbia

Development work, including diamond-drilling, has demonstrated that the orebodies in the Hidden Creek mine on Goose bay, near Prince Rupert, are larger and of higher grade than at first reported, according to Jay P. Graves, of Spokane, vice-president and general manager for the Granby Con. M. & S. Co., on returning from an inspection of the property, which was recently bought outright for $500,000 by the Granby corporation after a few months work under a bond. The orebodies, he added, extend at least to sea-level, or 1200 ft. below the outcrop.

"Data are being gathered to determine what the company's policy will be with regard to the treatment of the ores," Mr. Graves said in a reply to a question, adding: "We expect to reach a decision within 30 days whether we shall ship to custom smelters for a time or erect a plant to take care of our output and do a general business or treat our own ores. Should a smelter plant be built it will have a capacity of not less than 5000 tons a day. Already we have a saw-mill of 40,000 ft. capacity in operation and work will soon begin on a dam, which will give us a head of 350 ft. and develop 3500 hp. electrical energy for our new plant. A lighting plant is being built."

Charles F. Caldwell, of Kaslo, who was in Spokane a few days ago, reports awarding a contract for transporting 1000 tons of ore from the Utica mine over a rawhide trail to a siding on the Kaslo & Slocan railroad, having received assurance from the syndicate owning that road that it will be reconstructed and permanently operated in a short time. He also announced that he expects to finish the raise from the No. 5 to the No. 4 adit in 40 or 45 days, when a good force of miners will be put to work drifting and stoping. The Utica mine is situated on the Kaslo slope of the high range of mountains between Kootenai and Slocan lakes. It has been opened to depth by five adits. Several shoots of unusually high-grade ore have been developed.

Ontario

(Special Correspondence.)—Through diamond-drilling free gold has been found at the Pearl Lake mine at a depth of between 650 and 700 ft. in the schist as well as in the quartz stringers. The ore assays from $4 to $58 per ton. At the Rea mines a second shaft has been opened 160 ft. from the main workings, by making a raise from the 200-ft. level. No. 1 will be sunk 500 ft. farther, when it will be the deepest shaft worked in the camp. Much driving was done at the 200-ft. level, where free gold was found in the vein, which is 4 ft. wide at that depth. A continuation of the main vein has been found on the surface more than 1000 ft. from the shaft. Two shafts are being sunk on veins on the American Goldfields property, and ore extracted in development is being bagged. A rich vein showing much free gold has been discovered at the Eldorado mine. A new vein carrying high gold content has been stripped for 300 ft. on the Hollinger property. At the Jupiter, two shafts are down 100 ft., and cross-cutting has been started. The Apex has purchased a shot-drill and has ordered a compressor, two 50-hp. boilers, and two rock-drills.

Asbestos has been found by W. C. Richards on Falcon island, in the Lake of the Woods. The vein, which is 60 inches wide on the surface, has been traced for half a mile, and samples indicate that the deposit is of good quality. It is near a mica deposit.

Porcupine, September 15.

Porcupine news despatches state that J. W. Northrop has organized a $2,000,000 syndicate to develop claims in Bristol.

The vein has been uncovered for 300 ft. on the E. S. Chapin claims near Southeast bay, on Kenogami lake, Swastika, according to A. G. Terrill, who is in charge of the property. Sulphides are shown for the entire length uncovered.

(Special Correspondence.)—The Porcupine G. M. Co.'s engineer has completed his examination of the Vipond, and reports the vein to be 16 ft. wide and to assay $20.10 per ton. The cross-cut has not reached the south wall.

Porcupine, September 13.

MEXICO

Chihuahua

(Special Correspondence.)—The Rio Plata M. Co. has declared a quarterly dividend of 2%, payable September 29 to stockholders of record September 18.

Chihuahua, September 12.

Colima

It is reported that the Mamey iron deposits, owned by Arturo Le Harivel, of Colima, and associates, have been bonded to French interests, and that modern iron and steel works will be established there. The property was examined a short time ago by Ferdinand Sustersic. The price named is reported to be ₱500,000.

Sonora

La Cobriza Copper Co. has ordered three 100-hp. boilers, a double-drum hoist, and a 12-drill air-compressor for its mine 14 miles west of Noria. It owns 51 *pertenencias*, and has 3000 ft. of workings. The smelter will be blown in when F. C. Emery, president of the company, returns from London.

It is reported that the Richfield Copper Co. is constructing a smelter on its property, 18 miles southwest of the Santa Rosalia mine. A cyanide plant is being built at the Guergrito silver mine, on the Sherman ranch, between Cumpas and Nacozari. Ore will be treated direct. J. E. Humphries is manager of the property.

Most of the activity in this State is in gold, silver, lead, and zinc properties, and not in copper, partly owing to unsettled conditions and partly to the low price of copper. The situation has improved in the last few weeks, and there has been comparatively little labor trouble.

Ore assaying $20 to $129 in silver per ton has been discovered on the Rivera G. M. Co.'s property, in the Montezuma district. George J. Cole is manager of the mine.

Decisions Relating to Mining

Specially reported for the Mining and Scientific Press

Inspection of Mine—Judicial Notice

In the absence of testimony tending to prove the necessity of an inspection, a court cannot take judicial notice of the fact that general inspection of a mine is necessary.

Lewis v. Detroit Vitrified Brick Co., (Mich.) 129 Northwestern, 726. Feb. 1911.

Liability of Mine Owner for Injury to Miner—Independent Contractor

Miners who were paid by the hour for shale mined, and their hours of labor were fixed by themselves, except as it was necessary to adapt them to the hours when power controlled by the mine was furnished for hoisting cars, are not independent contractors so as to relieve the employer of liability for injuries to one of such miners, where it appeared that the mine owner furnished the track, cars, and place to work, and an agent who exploded the dynamite used, and where he reserved the right to discharge the men at any time.

Lewis v. Detroit Vitrified Brick Co., (Mich.) 129 Northwestern, 726. Feb. 1911.

Deed Reserving Minerals.

A deed conveying a tract of land contained the following reservation: "Reserving and excepting from said lands such as are now known, or shall hereafter be ascertained, to contain coal or iron, and also the use of such surface ground as may be necessary for mining operations, and the right to access to such reserved and excepted coal and iron lands for the purpose of exploring, developing, and working the same." This exception is not repugnant to the grant and is not void for uncertainty. The deed operates as a conveyance of the land with the exception of the coal and iron contained therein, reserving to the grantor the right to enter upon the same for the purpose of exploring and mining the minerals.

Carlson v. Minnesota Land & Colonization Co., (Minn.) 129 Northwestern, 768. Feb. 1911.

Injury to Miner—Contributory Negligence

A driver of a mule car in an entry of a coal mine discovered a derailed car in front of him too late to prevent a collision, because of a curtain hung across the entry. In order to avoid the impending danger he jumped from his car and was injured because of insufficient space between the side of the entry and the car. Under such circumstances the questions as to whether the space only six feet wide in the entry in which cars four feet wide are driven is a reassonably safe place for a driver to work, in view of the fact that there was a curtain across the entry preventing a view of any derailed car, and where it appeared that the track was not properly gauged and the cars often ran off the track, and whether it was contributory negligence for the driver to jump off his car, or whether he should have waited and tried to save himself, are questions for the jury. But the fact that the injured driver had disobeyed orders given him on the morning of the injury to the effect that he was to drive in front of the particular car that was derailed, is not sufficient to prevent a recovery where it is shown that his mule balked and on that account he was compelled to change places with the other car, as this was customary in the mine for the reason that a mule will frequently follow another car when he will not proceed otherwise.

Central Coal & Iron Co., v. Owens, (Ken.) 133 Southwestern, 966. Feb. 1911.

The American Zinc, Lead & Smelting Co. has declared a regular quarterly dividend of 50c. a share, payable October 10 to stock of record September 30.

Personal

Professional men are invited to send news of their engagements and travels. Such news is interesting to friends.

Fritz Wolf has gone to Eldorado county.

Philip Moore was in Denver recently.

W. S. Noyes has returned to San Francisco.

Courtenay De Kalb is in San Francisco.

W. G. Weber, of Chicago, is at Miami, Arizona.

F. W. Bradley is on his way home from Alaska.

W. C. Mendenhall was in San Francisco this week.

E. W. Walter, of Johnson, Arizona, is at Silverton, Colorado.

Frederick Lyon, of Kennet, California, is in San Francisco.

S. J. Weis has returned to London on his way to West Africa.

Gelasio Caetani is expected in San Francisco September 28.

Walter L. Reid, of Telluride, Colorado, was in San Francisco.

R. B. Lamb, of Toronto, has left for an extended visit to Porcupine.

W. B. Baggaley has left Mexico and is now at Short Hills, New Jersey.

H. L. Hollis hs returned from Valdez and was in San Francisco this week.

L. B. Herdman, formerly of Copper Hill, Arizona, has moved to Los Angeles.

I. Daimpre has left Tonopah, Nevada, for South Porcupine, Ontario, Canada.

R. B. Green, of Coram, is now with the Garfield Smelting Co. at Garfield, Utah.

B. B. Thayer, president of the Anaconda Copper Co., has returned from abroad.

Heath Steele, formerly of Goldfield, Nevada, is now with J. R. Finlay at New York.

W. H. Emmons, of the University of Minnesota, has returned to Minneapolis from Creede, Colorado.

H. W. Hardinge is now in Denmark examining mines, and will return to New York about November 1.

Alexander McLeod, of Nova Scotia, is examining the Cape Breton limestone areas for London people.

Inquiry is being made for the present address of B. M. Bates, who is requested to communicate with this office.

John Redington has been appointed manager of the Swastika mine in place of M. W. Summerhayes, resigned.

Ellard W. Carson, of Los Angeles, for the past two weeks has been making mine examinations near Victorville, San Bernardino county.

R. H. Elliott, of Pacific Grove, California, is now with the Ancobra Exp. & Dev. Co. at Tarkwa, Gold Coast Colony, British West Africa.

E. V. Daveler, of the metallurgical staff of the Utah Copper Co., is engaged in special work at the Ray Consolidated Copper Company.

A. P. Rogers, who has been engaged on professional work in Brazil during the past eight months, is now in London; he will return to New York shortly.

Frank H. Probert left Los Angeles for New York September 20 to be in consultation with Ray Central Copper Mining Co., and expects to be gone two weeks.

John D. Ryan is on an inspection trip to Cananea, Sonora, Mexico, accompanied by W. E. Corey, the former president of the United States Steel Corporation.

John M. Boutwell has finished a detailed survey of the mining geology of the Moctezuma Copper Co.'s property at Nacozari, Sonora, Mexico, and is now at Bisbee, Arizona, on his way to Santa Barbara, California.

Book Reviews

Any of the books noticed in these columns are for sale by or can be procured from, the Mining and Scientific Press.

The Mining Industry of Mexico; No. 1. State of Hidalgo. Part I. Compiled and edited by F. Gonzales, A. Grothe, and L. Salazar. Pp. 74, ill., maps, and charts. For sale by the *Mining and Scientific Press*. Price 50c., postage 15c. additional.

This admirable volume, the first of twenty parts dealing in an accurate and comprehensive manner with the mining industry of Mexico, has been compiled by a group of well known mining engineers on the initiative and with the assistance of the Department of Fomento. After a discussion of the topography and geology of Hidalgo, communications, postal facilities, and taxes, a list of the dividends paid by mining companies within the State during the last 18 years is given. The detailed description of the mining industry by districts follows, illustrated by numerous photographs, maps, and drawings, showing the equipment, ore deposits, and methods of working. Much of this information has not previously been easily available to the public and this gathering of it in one volume is of great service. Unfortunately, the mistake, so common in publications of this character, of not providing a copious index, greatly detracts from the usefulness of a work so painstakingly prepared. The volume concludes with a list of the institutions maintained by the mining companies for the benefit of their workmen.

Ground Water in Juab, Millard, and Iron Counties, Utah. By Oscar E. Meinzer. Water-Supply Paper 277, U. S. Geological Survey. Pp. 162, ill., index, maps. Washington, 1911.

Commercial Paragraphs

Lawrence N. B. Bullock, the well known metallurgical engineer, is now with the Mexico Mine & Smelter Supply Co., with headquarters at Mexico City.

The El Oro Mining & Railway Co., of El Oro, Mexico, has recently installed one of the largest motor-driven pump equipments ever built for unwatering a mine. The pump, which was built by the Goulds Mfg. Co., Seneca Falls, New York, has a capacity of 500 gallons per minute. The construction is such that the pump can be readily dismantled and lowered down an ordinary mine shaft and when assembled it requires very little head room. The pump will be installed in the bottom of the mine and will pump against a head of 1300 ft. The driving motor is a 200-hp., 3-phase, 50-cycle, 440-volt, 485 r.p.m. Westinghouse motor, which is connected with double reduction gearing giving the crankshaft of the pump a speed of 35 r.p.m.

EDITORIAL

MEXICO has been advertised mainly in the last year by the revolution, but a reading of the admirable presidential message submitted by Señor de la Barra September 16 shows that amid the noise and trouble incident to political change, matters have moved rather smoothly after all. A country that not only contracts no debt, but piles up a surplus during a period of civil war is manifestly far from needing surgical treatment by either native or foreign physicians.

AMERICAN ENGINEERS have been engaged to take charge of the operations of the Tata Iron & Steel Company at Sakchi, in Bengal, of which Mr. C. T. Perin has been consulting engineer. As the Government of India has guaranteed the new plant orders for steel rails and the Indian market is a large one, the new enterprise should be successful. American finance has recently played a prominent part in Persia and China, and new evidence of the spread of American influence is most gratifying.

MUTUALIZATION in a novel form was shown in the development of a mine in the Ely district, where a company, appropriately known as the Greek-American, arranged to board the miners and pay for their labor with stock in the company. The plan was surprisingly successful, and the mine has progressed to a stage where it has been able to contract with the smelter at Midvale for the treatment of its ore. The commissariat as the most important element in the finance of a mine is an unusual situation and the success of the venture is of much interest.

RAILWAY organs are protesting that if the lines must reduce through fares to the sum of the local fares, one-third of their passenger revenue will be lost. This is nonsense, as is apparent to anyone familiar with passenger rates. The average fare is not and has not been three cents per mile for years, and reduction to a two-cent base, the maximum threatened cut, would not therefore reduce revenues a third. Stopping the giving of passes and rebates has actually raised the average rate. The railways have their troubles and deserve sympathy in many particulars, but foolish pleas like the one now being made will do them harm rather than good.

SAN FRANCISCO has just passed through a hotly contested municipal election. Mr. P. H. McCarthy, candidate for re-election as Mayor, was defeated, not because he was a union labor candidate, but because he was a notably poor Mayor. Vice and inefficiency ruled in the city. The new election law assured an honest primary and required a majority to elect. This prevented the usual three-cornered fight. Mr. James Rolph, Jr., was elected Mayor and will serve through the period of the Panama-Pacific Exposition because the majority of San Franciscans are decent people and want honest government. In that they are representative of the great mass of the common people of the United States, who may be relied upon to decide a question right when it is placed fairly before them and opportunity is given for effective action.

ECONOMY of power is a large factor in the securing of low costs, and the performance of the new cyanide plant of the Portland Gold Mining Company, at Victor, Colorado, where the power consumption is given as $1\frac{1}{8}$ horse-power per ton-day, is worthy of notice. This mill, which is engaged in cyaniding the low-grade ores of Cripple Creek, without a preliminary roast, was devised and designed by the officers of the company, of which Mr. G. M. Taylor is manager, and in many ways exhibits notable steps in the progress of cyanidation.

A CITIZEN of the world passed away in England on September 20. Born in Ireland in 1835, Sir Robert Hart was for more than fifty years in the employ of the Chinese Government. As the reorganizer and director of the Imperial Maritime Customs he did signal service, sharing with 'Chinese' Gordon the honor of being the most distinguished foreigner of recent times who has aided in the development of China. Through his influence the postal service, telegraphs, and telephones were gradually introduced throughout the Empire, and have now reached a high state of development. Like most public servants, he was not free from criticism, and it has been urged that the keeping of the customs service largely independent of Chinese control and the gradual alteration of its personnel from international to predominantly British, were mistaken policies. The appreciation of his notable service by the Chinese Government was exhibited in the numerous honors accorded him, and the great reluctance with which he was allowed to resign when advanced age and ill-health made the duties of his high office too great a task. He was one of the born leaders of men, whom all delight to honor.

SYNTHETIC studies of geological problems are gradually clearing up many mysteries. The old notion that you could not determine how the world was made by looking into a crucible, has been shown to be properly susceptible to considerable modification. The classic work of Daubrée is being reinforced by researches of other investigators in many quarters of the globe. One of the groups that is doing most to solve fundamental problems of rock genesis is the staff of the Geophysical Laboratory of the Carnegie Institute of Washington. The chemical-physical studies of artificial feldspar by Messrs. Arthur L. Day and E. T. Allen, supplemented by microscopic work by Mr. Fred E. Wright, have gone to the root of many petrologic problems. Gradually a geological thermometer is being constructed whereby it is possible to tell from the minerals present the temperature at which rocks have been formed. In the last year the attention of these investigators has been turned to the study of ore minerals and of those associated with ores. We are privileged to publish this week a summary of the results of the work to date on the sulphides of iron, written by Mr. E. T. Allen. This will be read with great interest by all students of ore deposits. Definite criteria are given by Mr. Allen whereby the engineer may discriminate between deposits containing iron sulphide which were formed by heated, and those formed by cold waters. That marcasite is associated only with deposits formed by surface agencies, while pyrite characterizes ores of deep-seated origin, has been the belief of best informed students for some time. The belief, however, rested only on deduction from facts of field occurrence. Now the matter has been put to the test of experiment and the opinion of the geologists confirmed by the physical chemist. The significance of the rule is large. Any criterion for determining the pressure at which the minerals were formed and any positive means for discriminating the source of the heated waters is still lacking, but so good a start presages even more significant results.

DEFEAT of reciprocity by the voters of Canada is a disappointment to those who hoped for closer relations between the northern Dominion and the United States. Sentimental fear of annexation seems to have been largely responsible. It is difficult for those of us who live south of the line to realize that an occasional bombastic speech by some American politician has been taken so seriously. Certainly annexation is not in any sense a live subject in the United States. What was wanted was closer business relations. The proposed treaty was radically defective, but it was a step toward the closer relations that we would all like to see. To the plain average citizen there appears to be no more reason for a string of customs houses along the Canadian border than for one along the Mississippi. However, nothing but admiration can be expressed for the Canadian system which permitted a direct vote by the people on this important subject. We, with others, are sorry that the majority was against the treaty, but the acceptance or rejection of the American proposal was obviously a matter for Canadians to decide in accordance with their own belief as to which would further their best interests.

CONSISTENCY is said to be the bane of great minds. Evidently the *Canadian Mining Journal*, one of the cleverest and most readable of our contemporaries, is under no baleful influence. In a recent issue it very properly takes the *Canadian Courier* to task for ridiculous extravagance in 'writing up' the inventions of a former dental practitioner, now a self-made metallurgist. To this we say amen; more power to your arm. But it is closely followed by an editorial appreciation of the Evans-Stansfield electric furnace, which the *Journal* believes "has solved the riddle of cheap direct steel and * * * placed a premium upon numerous hitherto worthless orebodies in Ontario and Quebec." We have no special knowledge of the Evans-Stansfield process, but we prefer to believe that neither this nor any other small-scale furnace is likely to produce any immediate revolutions in the steel industry. The steel user is in no confusion of mind regarding all such processes. He knows that one of his essential requisites is the ability to secure steel of absolutely uniform and unvarying quality, in any desired quantity, over long periods of time. Five-hundred-ton blast-furnaces, sending their product to mixers that supply 50-ton steel furnaces are able to make a reasonable approach to absolute uniformity of product. Furnaces which produce but a few tons per day from ores of variable character will obviously make a variable product. Adequate methods for the treatment of Canadian magnetites would be a great asset to that country, but the desire for them should not lead to a too hasty proclamation of their advent.

Alaskan Problems

ALASKA and its coal problems seem likely to vex the Nation for some time to come, though real information about the fields is beginning to be available. It is evident that the present value of the coal has been grossly overestimated; in part by those interested in floating securities based in some form on the coal, and in part by conservation writers unfamiliar with practical coal mining. In the Bering River field this summer there were about a half dozen men at work, and they were acting mainly as caretakers. In the Matanuska field there were two watchmen, and while much money had been spent on trails and other necessary preliminary work, no real mining had been undertaken. Apparently the development of both fields has been in the hands of promoters and men familiar only with Western metal mining. Coal miners have been conspicuously absent. It is well also to remember that rival townsites enter into the problem, and who does not know the wiles of the real estate man? A recent visitor to both coalfields, himself formerly foreman of coal mines, writes that it "would break a foreman's heart" to mine under the conditions obtaining in either. In the Bering River field the coal is pockety and faulted, and it is by no means certain that the less well known Matanuska field does not afford the better opportunity for a commercial enterprise. We have already expressed our opinion that all the needs of the present situation can be met by opening a mine to supply Government and local needs for coal. At moderate expenditure the real value of the field can be readily determined. In our opinion there is much more apt to be loss than profit, so far as the mine is concerned, but it will be the cheapest way to get desirable information. Further steps should be taken only after careful consideration of details. In this issue Mr. Bain discusses one plan for meeting the broader problems involved. It is evident that these run into the larger question of control of monopoly and as to that there is room for much difference of opinion. The subject is big and important. The committee on mines and mining of the House of Representatives has appointed a sub-committee to draft and present a bill covering the Alaska situation, and now is the time for thorough discussion.

The Mint and Its Critics

Whenever the Government undertakes any form of business, prompt conflict with private concerns ensues, and there is widespread recognition of the unfairness of the Government's competing with its own citizens. We do not believe that this is a sufficient reason why the Government should never undertake a business enterprise, but it does emphasize the need of most careful consideration before either the State or the Nation enters any such field. In many countries schools are private enterprises, and in the United States there are many private schools, yet one would go far to find a man who considered the business of educating citizens an improper field for governmental activities. The postoffice, though a great business enterprise, is so manifestly for the general good that there were no serious proposals to turn it over to a private corporation, even during the long years when it was conducted at a loss. Mr. Frank R. Stockton once wrote amusingly of the 'Great War Syndicate' which he pictured as offering to conduct a foreign war for the unprepared Government. Military defense, though a business, is so clearly a Government function that there was humor even in the suggestion of letting a war out by contract. Evidently there is no hard and fast rule by which to determine what business is proper and what improper for the Government, and each case must be considered on its merits.

For many years the coining of money has been conceded to be exclusively a Government function, and in the practical operation of the mints a big business has developed in buying and refining gold and silver. As a practical convenience assay offices have been established at many points where bullion may be sold to the Government, and the Mint service has expanded with the growth of the country. There have been good reasons why the service should expand, but there should also have been a concurrent lopping off of old plants as changed conditions made them useless. Improved transportation facilities have made unnecessary the maintenance of some of the assay offices, but it is as difficult to get one abandoned as to cut off appropriations for an outgrown and useless navy yard. This is one of the defects of the system under which Government business is done. The great appropriation bills are never really debated and never understood by more than two or three men. It is impossible that they should be carefully revised each year, and an item once placed in one of the regular bills is apt to remain undisturbed for years. It is related that the Superintendent at West Point put in a request year after year for funds for building a stone wall, but that in the interest of economy the item was always cut out by the committee. One year a more lenient chairman let it stand, and thereafter for a series of years Congress solemnly voted money for that stone wall, until walls became so common at the Academy that more ground had to be bought to accommodate them. In the same way old plants have remained in the Mint service long after their usefulness was ended, and this has given a leverage to critics.

Last winter Congress passed a sensible and proper measure making it possible for the Director of the Mint to receive and refine gold and issue certificates against it without coining. This reduces expenses, decreases loss by abrasion, and does away with the absurd practice of coining gold eagles for shipment to England where they are melted down and recoined into sovereigns. Gold bars are much better for settling foreign balances, and in ordinary trade gold certificates are superior to gold itself. The change will necessarily throw out of employment certain employees. Little economy would otherwise result. From this, from pressure for abolishment of useless assay offices, and from the circumstance that the new law does not state the fineness of the bullion against which the Director of the Mint may issue certificates, has arisen a fear in some quarters that the Mint will go out of business and all refining will be turned over to private companies. In our discussion department this week the matter is treated at length by Mr. Harold French, who approaches it from a frankly prejudiced viewpoint. For our own part we do not believe that any attempt is being made 'to put the Mint out of business,' and a project "to corner the gold supply," of which one hears whispers, seems to us too absurd to receive serious consideration. The Mint, we believe, should receive and refine all gold offered it and for which a Government certificate is asked. It should have a reasonable number of properly placed branches and receiving stations, and we have no doubt that this service will be maintained, even though a great decrease in operating force and expenses results under the new law. But the Mint, as well as other branches of the Government service, should no longer be obliged to bear the expense of maintaining branches whose chief usefulness is to advance the fortunes of some group of politicians. The Bureau of the Mint is doing excellent work. It is in the hands of a particularly competent Director and has in its service a force of exceedingly capable employees. So long as its affairs be conducted on a business basis, it has nothing to fear from opposition of business interests.

It is interesting to note, in passing, that the plan of exchange of gold bars upon the basis of their weight and fineness is essentially an adaptation of the method which has been followed in China for many centuries. All large business transactions throughout China are paid in warrants calling for the requisite number of ounces of silver of a specified fineness. Unfortunately, each province formerly employed a different degree of fineness and the ounce was equally variable, leading to an extremely complicated financial system. Some years since, the United States Government loaned to China the services of Mr. J. W. Jenks to devise a method of simplification, and more recently Mr. L. J. Hatch, of the Bureau of Printing and Engraving, has been engaged in organizing the work of the issuing of banknotes by the Ta-Ching, or National, Bank.

Alaska Coal Mines and a Coal Monopoly

By H. Foster Bain

In discussing the Alaska coal-land situation it is commonly assumed that the matter is primarily one of conservation. This is far from being true. Any analysis of the speeches that have been made and of the papers written on the subject, will make clear that distribution of profit rather than waste of coal is what the proponents of change have chiefly in mind. Engineers, on the other hand, are primarily concerned with development, and as conservationists their interest centres mainly upon securing development with the minimum of waste. As has been repeatedly pointed out, development can be expected only if some profit accrue to, or be anticipated by, the developers. Avoidance of waste is a matter of securing the best technical service in the actual conduct of an industry. Economic considerations determine the conditions under which development may or must proceed; the engineer determines how best to meet a given set of conditions. Any circumstance which permits more money to be spent on a given process or a larger control of an industry to be exercised, makes possible a greater saving of material. Higher prices and larger units of business organization make for a less waste of coal or any other material. A single syndicate mining and selling Alaska coal would undoubtedly conserve both coal and capital better than any other organization. To turn the matter over to such a syndicate would be the simple and business-like method of procedure—if these were the only considerations. It is evident, however, that such a bald solution of the problem would satisfy no one except the members of the syndicate, and some other method or some modification of this one must be found if progress is to be made.

In examining the matter, two different points of view must be kept in mind. On the one hand there are those who believe in progress under existing laws and customs, and, on the other, those who demand change. The first group includes those who have been active in development of the West and to whom the old ways, if not entirely satisfactory, are at least understandable. They point to the fact that under existing laws and customs the resources of the various Western States have been successfully utilized to the great benefit of the country at large as well as of the individuals active in the industry. Some injustice has resulted; some injustice results under any system of government or business. The country has, however, actually developed, and the people have been materially benefited. The men in this group are anxious and willing to apply the same methods to the opening of Alaska—our last great frontier territory. On the other hand, there are those who, admitting the good that has flowed from the past, point to the accompanying evils and insist that even better methods for securing development may be found. Specifically they desire to protect the average citizen from extortion following monopoly, and to prevent the accruing to individuals of the unearned increment on mineral lands now in public ownership. Stated in this form it becomes evident that the matter goes deep. The problem is world-wide and is to be faced in every industry. Its solution as regards the existing public mineral lands would be but an incomplete answer to the great needs of present civilization—(1) the realization of the benefits of large business organizations without loss of control of monopoly; (2) the equitable distribution of the surplus earnings of mankind. Solution of the Alaskan coal problem will be at best but one small step in the solution of the general problem, and any method applied in Alaska and based upon Government ownership of the land can be of but small immediate importance, since for many years to come the people of the United States will draw the bulk of their fuel from fields that have already passed into private ownership. It is true that approximately one-third of the known coal is still owned by the general Government. This, however, is undeveloped. The practical question is whether it can be opened under regulations that will rectify mistakes flowing from past policies, or at least prevent similar mistakes in the future.

The great anthracite deposits of Pennsylvania are already in the hands of a monopoly and in a large measure the enhanced value of the land has already gone to the individuals concerned in organizing and maintaining it. There is no question but that the industry has been benefited, but there is widespread popular dissatisfaction with the control exercised in this case by private individuals, and the Government finds itself estopped from effective regulation of the industry by the fact that the lands are owned privately. In the bituminous coal-mining industry, on the other hand, conditions are chaotic and intensely unsatisfactory to everyone concerned except those large users of steam coal who put low price above every other consideration. The average citizen who buys in small quantities is already paying high prices. By stringent anti-monopoly laws, especially the Sherman act, the tendency toward monopoly was halted before the bituminous coal-mining industry became completely organized. It would, however, be extremely difficult to reach a fair and disinterested conclusion as to whether, from the point of view of the general public, present conditions are more unsatisfactory in the anthracite or the bituminous fields. Low prices do not tell the whole tale. Wasted capital, wasted coal, low wages, and lost lives, the formation of a large class of permanently discontented workmen, all these must be counted against low prices of coal used by railroads and power companies, granted even that low prices to the latter mean some benefit to the ultimate consumer of transportation and power. In any event, the coal lands of the East and Middle West have passed into private hands, and, however successful a leasing system or Government ownership of mines might prove in the West, the main problems would remain unsolved in territory where the most people live.

An instructive lesson none the less may be drawn from the anthracite fields. Many persons forget that for years coal was mined and sold there under fiercely competitive conditions. At a time when it cost but $1000 to open a mine and $10,000 sufficed "for quite a respectable business", many rushed into the industry. Overproduction worked the inevitable result of low prices and no profit. Since, however, there was a profit to the railroads in transporting the coal to the market, mining was stimulated by loans from the railroads to the struggling coal companies. Eventually the railroads had to take the mines to protect their loans and then discrimination in rates and service became inevitable. In time the cost of opening mines rose to almost prohibitive figures and no one could afford to invest the large sum necessary unless he also controlled transportation. All these factors worked together to produce the inevitable result, a monopoly of anthracite mining in the hands of the railroads. From many points of view the results have been excellent. The properties, however, are operated, not for the sake of the mines, but for the railroads, and a great national industry is subordinated to the immediate necessities of a group of roads. For many years there was no profit in mining anthracite; probably there is little now. Millions have been paid in royalties to fortunate owners, more millions have been made in the business of transporting and marketing the coal; but in the business of mining itself, there has been no considerable profit. There has always been a surplus of mines and of railroads in the anthracite fields, and, the larger capital being invested in the railroads, it was inevitable that they came to dominate the situation. The State and the National legislators never aided the industry by constructive legislation based upon any real consideration of the larger problems of the people and the coal. When they acted they merely pecked at the industry with petty restrictive acts. The net result is a firmly seated private monopoly of a great national resource.

In the bituminous coalfields the story is similar to that of the anthracite fields in the early years: an abundance of coal and of capital, investments made on the basis of an inflated industry during boom times, overproduction, idle plants and men, wasted money and coal, attempts of the railroads to control production each in its own interest, and the formation of monopolies in limited areas. The tendency toward a larger monopoly has been checked by anti-monopoly legislation, and the regulation of interstate commerce. In the meantime many idle collieries stand gaunt and rusting in the valleys and on the prairies, and an idle plant does no service for any man. It is useful only as a club in considerations of rates and prices. Clubs, it is well to remember, are the weapons of the stone age.

The two industries exemplify the effects of combination on the one hand and of competition on the other. In 1891 under competitive conditions anthracite sold at the mine for an average price of $1.73 per ton. In 1910, under monopoly conditions, the price had risen to $2 per ton, an increase of 16 per cent. In the same years bituminous coal under competitive conditions rose in price from $0.99 to $1.12 per ton, an increase of 13 per cent. These figures are no measure of retail prices, but it is evident that whatever may have been the effect as regards consumers, the creation of a monopoly in the anthracite fields has benefited producers of coal more in other directions than by increase in price. It is important to remember in this connection that the cost of selling and delivery is a large element in retail price of coal, as of other products, and often the buyer of small lots imputes to the original producer charges that originate long after the coal reaches the top of the ground. It seems clear, on the whole, when the two industries are contrasted, that combination rather than competition yields better results. To secure its full benefits without injury to the public is the real problem, and some form of public control is evidently desirable. The simplest form of control yet found is ownership. It does not follow that public ownership of all the coal mines is either desirable or necessary, but, so long as the Government already owns one-third of the coal reserve of the Nation, this coal should not be allowed to pass into private hands until some adequate means of meeting the problems outlined, has been found and tested. It has repeatedly been proved that ownership of a majority of the stock is not necessary in order to control a corporation, and a holding of one-third of the coal is so much greater than any possible combination of lands privately owned, that, particularly in combination with its other powers, the Government can determine absolutely the future of the coal business of this country. The Government ought not sell the coal lands until the whole matter is settled. In the meantime, all the demands for development can be amply met by a simple leasing system such as has been proposed by the Administration. There is no benefit to be derived from locking up the coal lands in either Government or private hands, but to sell them irrevocably at nominal prices and in quantities in excess of the needs of present development, is on a par with the giving of perpetual franchise for municipal utilities. The leasing system may or may not prove the correct procedure as a permanent policy, but for the present it has many advantages over any other.

The problems that now confront our bituminous coal-mining industry arose a few years ago in the same form in Germany. In that land of orderly industry, the coal business was in as bad condition as was ever that of Pennsylvania or any other American State. There was this difference, the Prussian Government as the owner of many miles of railroad was concerned, in place of, as in America, a group of private individuals; but further, the Government there did not, as here, own a large part of the known coal. Difficulties in railroad operation, as well as the general disorganization of industry, focused public attention on the coal industry. The State railways sometimes enjoyed cheap coal and at other times paid dearly for it. At times the lines had much traffic and at other times little. For short periods the collieries made large profits, and these periods were succeeded by long lean years. The methodical Germans studied the situation and then met it in a practical manner undeterred by theoretical considerations of what might happen. The Government purchased enough mines to give it control of approximately 40% of the coal producing capacity of the country. Then, on the basis of the ownership of these mines and a thorough knowledge of the business, the Government joined in a syndicate for mining and marketing coal. While there has been some criticism of the results, there has been steady work, moderate but regular profits, and better prices. English coal companies, it is true, have made inroads on the Berlin market, but the Germans gaze with equanimity upon this. They regard the low-priced coal furnished by competing English companies as just so much gain. Germany has regulated the coal monopoly by becoming a party to it.

I am among those who believe that 'trusts,' meaning thereby large business organizations, are inevitable. The conditions of modern industry favor them, and their economic advantages outweigh their evils. It is not necessary, however, to allow them to proceed unregulated, and to do so is as foolish as to allow unrestricted employment of any other new device, such as automobiles or wireless telegraphy. Trusts need regulation, but if business is to be conserved, it must be by informed and sympathetic regulation. The best way to control a trust is through the board of directors. Even a minority there will be listened to with respect, and suggestions, if sensible, will be adopted.

In Alaska the conditions of industry are naturally adverse. It is extremely difficult to successfully develop an enterprise, and only the most efficient form of organization can hope for more than sporadic success. The coalfields may be developed more quickly, economically, and efficiently by a single great syndicate than by a number of small warring concerns. The *Mining and Scientific Press* has already expressed the opinion that the first step in the solution of the Alaskan coal-land problems should be the opening of a Government mine, primarily to supply the Government needs of coal, and that, if necessary, the Government should build the needed railway to the mines. The second step should be the opening of private collieries on leased ground and the formation of a selling syndicate to pro-rate all contracts. The Government itself should be a member of this syndicate and should be represented in its management by an expert resident official of ample authority. If any of the present claimants of lands succeed in getting patents, they should be invited to become participants in the syndicate, and they would probably find it greatly to their advantage to join.

In putting forward suggestions for solution of the larger problems involved I would not be understood as urging them as either final or complete. It is hoped rather that they may provoke discussion that will result in evolution of a satisfactory general policy. In the meantime I cannot forbear recording again my own belief that the immediate value of the Alaska coalfields is small and their future value is problematical. If the plan of opening a Government mine be adopted, and if patents be promptly granted to any claimants entitled to them, the present situation will be relieved and ample time can be taken to determine the best possible policy for the future. The most essential thing is to provide for mining some coal now and still leave the policy of the future to be shaped to meet its own needs. This seems to me to be most easily accomplished by following the opening of the Government mine with an offer of a limited number of leases to anyone who may care to undertake the risks involved in opening collieries in Alaska. These risks, from a business point of view, are bound to be large for many years, and the Government in offering a lease should be prepared to safeguard in every reasonable way the lessees as well as the public.

Leases should be granted upon liberal terms, fixed in advance, should run for a period of preferably 25 years, and should cover in each case sufficient area to permit continuous operation of a modern plant through the life of the lease. The royalty should be low, since a healthy industry is more important than is revenue to the Government, and it is no proper function of the Government to make money out of one industry or class of citizens to the profit of others. The number of leases operated at any one time should be restricted to correspond to the probable market for coal. Whenever, however, the existing collieries become unable to supply the demand, or the profit on the business for two successive seasons amounts to more than a fixed percentage on the capital invested, due allowance having been made for maintenance and sinking fund, the Government should offer additional blocks of ground for lease, and the new collieries, when open, should become members of the selling syndicate and should receive their *pro rata* of contracts. Leases had best be let by competitive bidding. By this method the companies would fix their own royalties. In the initial competition they should be allowed to offer alternative bids based upon the number of leases that it may be decided to let. Clearly, a company having the whole business can pay a higher royalty than one which must divide the trade with others. It is true that competitive bidding has disadvantages as compared with assignment by lot or in order of application, but among those familiar with the business and having the capital to carry out the terms of the lease, bidding would be equal, and there can be no advantage in having others undertake to open collieries.

All applications for leases should be accompanied by bond, and after two years within which to open the mine, royalties should be collected for the proportionate tonnage of each year whether coal be mined or not. Such royalties should apply on future production, their payment being merely required to prevent indefinite suspension of operation. The detailed terms of the suggested leases might profitably be varied somewhat, but the following general principles should be held to: (1) Terms liberal and known in advance; (2) all companies to participate in sales and contracts; (3) the Government to be fully informed of all details; (4) the Government to be in position to prevent extortion by permitting the opening of additional mines; (5) royalties to be determined by the companies themselves by means of competitive bidding; (6) revenue over and above the cost of maintaining the service should go in large part, if not entirely, to the local Territorial Government; (7) leases should be freely transferable and subject to cancellation only for material failure to observe their terms and after court review.

Until the California oilfields begin to show signs of depletion, it is not likely that development of an Alaska coal-mining industry will be rapid, but under the plan suggested above, every opportunity would be afforded for opening mines as fast as the market could be developed, and that without sacrifice of any interest present or future. Such a complete change in policy should not be attempted on too large a scale at once, and for that reason it is suggested that the plan be applied to Alaska only at present. If the results prove satisfactory the same system can be extended to the remaining coal lands in the States, and there can be little question that a selling syndicate of this sort could bring to the bituminous coal industry all the benefits now apparent in the anthracite mining region, without sacrifice of public interests. The advantage of the leasing system is that it does not unduly commit the future of the industry, and as new leases came to be given from time to time the companies would offer higher royalties if the business warranted, or the price of coal would fall. In either event the 'unearned increment' would accrue to the public rather than to private individuals. The plan does away with speculation in the land, which is exactly what it is designed to accomplish. It limits the amount of speculation possible in leases by fixing a maximum profit that may be realized. By way of compensation it also limits the chances of loss by restricting competition, and by throwing on the Government much of the expense of pioneering, in that the Government mine, to be opened first, must have transportation facilities and later comers may enjoy these equally with the Government. It meets or attempts to meet the Western objection to leases, namely, government from Washington, and constant interference as to details, by requiring the terms of the lease to be fixed in advance and that leases shall only be canceled in the same manner and on the same grounds as are private contracts. A further important feature of the plan is a resident official with ample authority to exercise the somewhat limited discretion proposed. No attempt is made to fix prices. These will be determined by competition of Canadian and American coal, California oil, and the cost of hydro-electric power. The limitation is as to profits and that is to be enforced in the normal method by bringing in additional competition when profits become too large. An orderly rather than speculative method of setting this force into play is provided. The official whose duty it will be to offer new leases will be fully informed as to the facts and must proceed according to fixed conditions known in advance. Finally, his judgment will be put to test, since unless the showing of large profits or insufficient supply be satisfactory, no competent bidder will be found when the leases are offered. In the meantime the producers are protected against cut-throat competition among themselves, the power of the Government is available to compel fair transportation rates, and the selling of the product, the most difficult and delicate part of the coal business, is in the hands of the companies and not of the Government. The plan provides for placing the producing companies upon the best economic basis that competition of other fields will permit, and under these conditions they will be prepared to mine coal according to the best practice that is now possible. Conservation of coal and protection of life in the mines must be enforced through the police power of the State and regulations directed to that end must be matters of law. In order to secure good regulations and their vigorous enforcement, however, the operating companies must be placed in a satisfactory financial position. This is only possible when they are protected against unfair competition and unreasonable capitalization.

It is too much to assume that any plan will prove entirely satisfactory, but the above is offered as one which at least takes account of the difficulties and provides means of meeting those that can be foreseen.

Resoiling Dredged Areas

When, a couple of years or so ago, the conflicting claims of agriculture and gold dredging were being vehemently discussed, P. J. Tewksbury, on behalf of the Tewksbury Proprietary G. D. Co., undertook to plant a large area of dredged ground in order to show that the soil had not been rendered unfertile by the process. Black wattle was the tree selected for the experiment, and the seed was duly sowed. It is satisfactory to learn that an officer of the Mines Department has reported favorably on the result. The crop is said to be thriving well, some of the young trees being already $7\frac{1}{2}$ ft. high, and measuring $1\frac{1}{4}$ in. diam. at 6 in. from the ground. The trees range in height from $1\frac{1}{2}$ to $7\frac{1}{2}$ ft. Several other instances have been mentioned from time to time in which proof has been forthcoming that dredged ground is not sterilized. Certainly, wherever it is possible, a sufficient depth of surface soil, secured by advance stripping, should be replaced on the surface, so that the least possible injury should be done, and it is well that, in general, this should be required of lessees. But where the surface soil previously covering the gravel was shallow, it is clear that an insistence on resoiling only deters the dredging industry without aiding agriculture in the slightest degree. A dredge master states that it is advantageous to his company to use a chute when there is a fair quantity of overburden, because of increased gold return when the washes are separately treated.—*Australian Mining Standard.*

Historical Notes on the Air-Lift Agitator

By J. W. Swaren

Early in the year 1880, the Tonite Powder Co., a British corporation, built a powder factory in Contra Costa county, California, to supply the Pacific Coast States with 'tonite,' a safety powder made from gun-cotton and barium nitrate. To wash the gun-cotton and remove the last traces of acid a pneumatic agitating device, identical in theory and similar in design to the agitator now known as the Pachuca or Brown tank, was built. The original idea came from England and how long it had previously been used in the English factory of this company I have been unable to ascertain.

Referring to Fig. 1, accompanying, the general dimensions and appearance of the tank will be seen. It was built of redwood, like a truncated pyramid, with the smaller base down. It was 16 ft. high, the upper base being 8 ft. square and the lower base 3 ft. As first constructed no central tube was used. Air under a pressure of 12 to 15 lb. per square inch was admitted into the bottom through a nozzle, and agitated the mixture of gun-cotton and water with which the tank was filled to within about four feet of the top. This tank was operated with fair results until about 1882, when William Letts Oliver, the manager for the Tonite Powder Co., conceived the idea of using a central tube, as shown in the illustration. A tapering tube 18 in. at the top and 12 in. at the bottom, 7 ft. long, was constructed, with its lower end 2 ft. above the bottom of the tank. The nozzle of the air-pipe was extended to reach just inside this central tube. The agitation was very much improved by this tube, and was found to be best when the larger diameter of the tube was at the top. After this tube was introduced, the charge would settle in the bottom when agitation was stopped to permit decanting, and the air did not have sufficient force to set the charge in motion again. To overcome this a jet of air was admitted through a pipe entering at one corner, as shown. This effectively broke up the cake and started the charge. This tank is still in use for agitating gun-cotton at the works of the California Cap Co., which purchased the plant of the Tonite Powder Company.

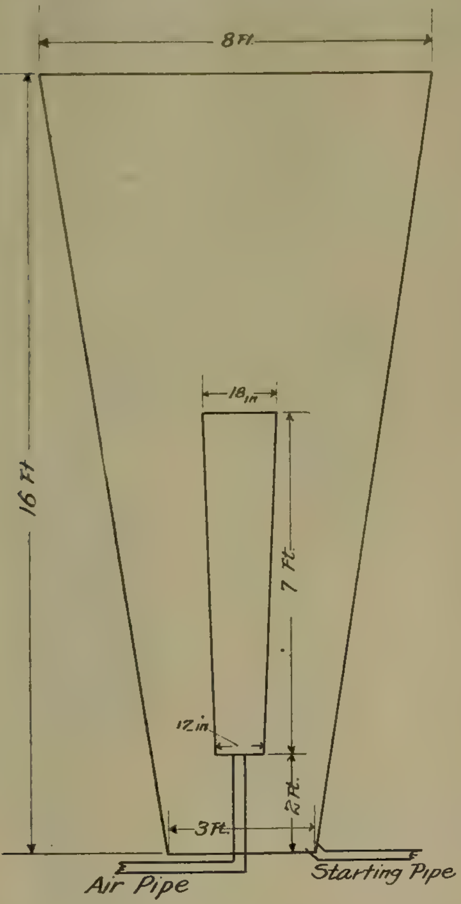

FIG. 1.

In the late eighties, Mr. Sommers, of the University of California, discovered that sulphur bichloride (SCl_2) had the extraordinary property of changing the nature of animal oils, and the discovery was believed to be of great commercial value. However, the reactions set up were of such violence that difficulty was experienced in getting a proper mixture. He consulted Mr. Oliver, who suggested using an agitator similar to that described above. In 1890, the American Lucol Co., of which Mr. Oliver was manager, erected a plant at Stege, to manufacture lucol, a composition of fish oil, kerosene, and sulphur bichloride, an excellent substitute for linseed oil. Fig. 2 shows the general scheme of agitation employed. A redwood tank, 16 ft. high and 8 ft. diam. was erected. The central tube was 18 in. diam., 8 ft. long, and 1 ft. above the bottom of the tank. This tank was filled with fish oil above the central tube, and the air admitted. Sulphur bichloride and kerosene were then run in simultaneously from tanks arranged as shown in the sketch. Considerable care had to be exercised in mixing

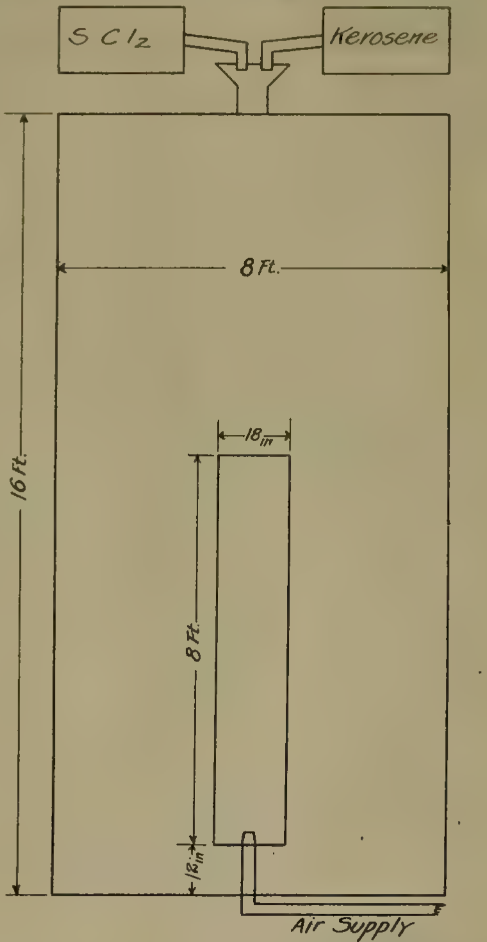

FIG. 2.

these ingredients, as the sulphur bichloride and fish oil mixed alone made a hard rubbery mass, while the kerosene and fish oil emulsified. To prevent this, the mixing of the ingredients had to be very rapid and thorough. An air pressure of 12 to 20 lb. was used in the central tube.

The operation of this agitator was so satisfactory that in 1894 four similar tanks were constructed in a new plant for the American Lucol Co. at Carteret, New Jersey. These tanks were steel, with 18-ft. sides and 10 ft. diam., with 16-in. central tubes 12 ft. long, as shown in Fig. 3. These tanks were used continuously until the American Lucol Co. went out of existence in 1896. A novel means for determining the rate of agitation was employed in this process. Small bits of colored paper were introduced in the tank one color at a time, and a sample taken from the different parts of the tank gave a visible indication of the remarkable efficiency of the agitation. These pneumatic agitators antedate the experiments of F. C. Brown at Komata Reefs by some years. According to his contributions to the *Mining and Scientific Press* September 26, 1908, the first pneumatic tanks were installed early in 1902, and the central tube was not introduced until 1904. Pneumatic agitators with central tubes had been employed at the North Star Mines, Grass Valley, California, previous to 1904.

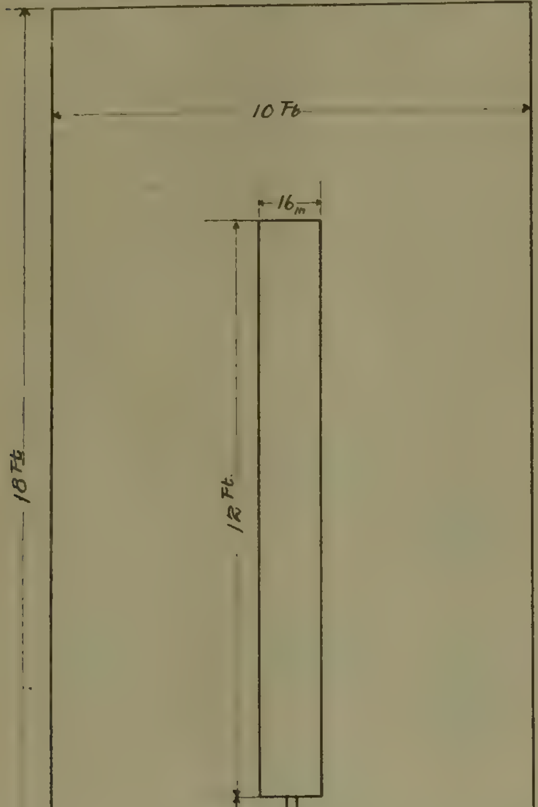

FIG. 3.

During the summer of 1903, Edwin Letts Oliver, metallurgist for the North Star Mines Co., Grass Valley, California, and son of W. L. Oliver, began experimenting with electrolytic processes for recovering the metal content direct from cyanide treated pulp without separating the solutions or using zinc. In this work thorough agitation for the pulp was necessary, as well as some means of bringing the pulp into the electrolytic field of action. A steel tank with 5-ft. sides and 20 in. diam., with a 45° conical bottom was constructed. A 2-in. central tube was used with the lower end 5 in. above the apex of the cone, and its upper end 10 in. below the top of the tank. The nozzle of the air-pipe extended into the central tube. A spreader board was suspended over the top of this tube. The amalgamated copper and iron electrolytic plates were suspended in the annular space, surrounding the upper end of the central tube. Fig. 4 shows the general arrangement of this agitator. This tank was constructed in August 1903, and proved sufficiently efficient to warrant the construction of additional tanks.

In December 1903 two additional tanks were built of wood, with 12-ft. sides and 60° cone, and 6 ft. diam. The central tube extended from 1 ft. above the apex of the bottom to about 18 in. from the top of the tank. A spreader board 10 in. diam. was suspended 6 in. above this tube. The first tube used was 3 in. diam., but this did not give sufficient agitation and was replaced by an 8-in. tube. The nozzle was placed inside the tube at first, but was gradually shortened until it was inside the 4-in. discharge pipe, and just below the apex of the cone. When the central tube choked, as it did occasionally before the nozzle was shortened, the spreader board was removed and a cover board attached. A lever was placed on top of the tube. This lever was held under a cleat at one side of the tank and forced up tight by a screw device on the opposite side. Air under 80 lb. pressure was then turned into the air-supply pipe, quickly and effectively breaking up the compacted pulp. Fig. 5 shows the general arrangement of these tanks.

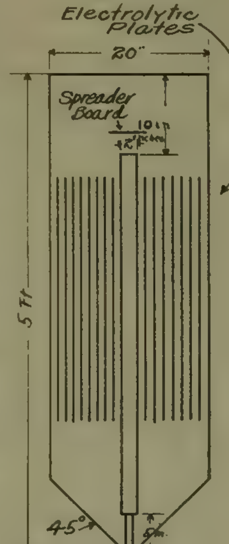

FIG. 4.

A few weeks after these two were completed a third tank was built. In the spring of 1904 twelve larger tanks, six for the North Star and six for the Central cyanide plant were built, 8 ft. diam., 14-ft. sides, with 60° cones and 8-in. central tubes with spreader board and cover board for breaking the pulp when the tube became choked, as shown in Fig. 6. The pulp originally sent to these tanks was concentrator tailing crushed through a 30-mesh screen at the battery. Later, to increase the capacity of the cyanide plant, the sand was classified out, and leached. The electrolytic plant worked as described until January 1905, giving approximately 75% recovery. This process, which is described fully in U. S. Letters Patent No. 784,120, worked beautifully in theory. Copper plates were used for cathodes and 1/8-in. iron plates for anodes, 1000 sq. ft. of cathode per agitator being used. The pulp was agitated in a solution containing 0.05% KCN and 0.05% CaO. No salt was needed to increase the electric conductivity of the solution. Contact was made between the cathode and current supply by specially shaped mercury cups, which permitted the mercury to spread over the plate, thus constantly refreshing the mercury surface. The layer of amalgam was formed on the copper plates as in ordinary amalgamating practice. The most economical density was found to be about 50c. gold per square foot. Agitation was intermittent, 6 hours being the usual length of time given to each charge. For cleaning up a smaller tank was used. Once a month the copper plates were transferred to the clean-up tank. The direction of current flow was reversed, the amalgamated copper plates becoming the anodes and planished iron plates were used as cathodes. Clear cyanide solution was used for electrolyte. In precipitating a current density of 0.05 amperes per square foot of cathode was found to give best results. In the clean-up tank, however, this was raised to 20 amperes per square foot, the object being to strip the copper plates as rapidly as possible. Usually three or four minutes sufficed to strip the copper plate of amalgam, which was then removed and re-amalgamated with fresh mercury.

The amalgam formed on the planished iron cathodes during the clean-up as a thick grayish sponge, 1/4 in. or more thick. With such a thick layer of amalgam, more or less would shake off in handling the plates. The clean-up of the sludge in the bottom of the tank usually yielded two or three hundred dollars. When a sufficiently thick layer of amalgam was formed, the plates were removed, the amalgam wiped off, and excess mercury removed by squeezing through canvas in the usual way. On retorting, the bullion ran approximately 400 gold, 350 silver, and 250 copper, when all parts of the equipment were operating to the best advantage. The clean-up could be controlled by the current density, weak currents scarcely affecting the mercury, and depositing copper only on the iron cathode. A stronger current dissolved and deposited some silver and mercury, while a very strong current density formed a deposit high in gold, silver, and mercury, but low in copper. Complete separation of gold and silver was never attempted. The most satisfactory working was obtained when depositing an amalgam retorting a bullion of the composition given above. The electrical equipment used for this work consisted of a generator rated at 1200 amp., 5 v., driven by a 10-hp. motor.

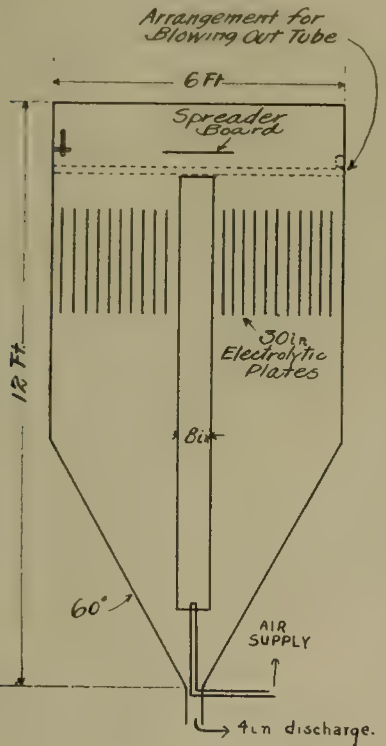

FIG. 5.

When leaching the sand was begun, new conditions were met, as the solutions from the sand vats were precipitated by zinc. Barren solution from the zinc-boxes was pumped into the electrolytic tanks. The zinc in solution was precipitated with the gold and silver. When the plates were cleaned up, and the amalgam retorted, the gold-silver-copper-zinc bullion resulting was a brass, having the color of good gold bars. The weight, however, was light. In one instance the assay value of a beautiful bar was guessed from $5 to $12 by different employees. The assay showed $3. This bar would have turned any gold brick artist green with envy. The iron oxide, ferrocyanide, and other ferric and ferrous compounds, of which considerable quantities were formed, were at first discharged in the creek. After the plant had been in operation some time, an assay was made of these compounds. This showed a value in excess of $200 per ton. After this all scrapings and rust were saved, even broken and discarded plates yielding $75 per ton. In January 1905, Acheson graphite was substituted for the iron anodes in the treatment tanks. The same current density was employed. Following the introduction of the graphite, an attempt was made to cyanide concentrate, but the sulphides attacked the graphite, disintegrating it very quickly. The experimental work here described was carried on at the North Star mill. During the summer of 1905 the three original agitators were transferred to the Central mill of the North Star Mines Co., for treating concentrates. In October of that year the Central plant was enlarged by the addition of sand leaching.

Early in 1906 electrolytic precipitation was abandoned. Pneumatic agitation was retained, however, using the same agitators, but removing the electrolytic plates. Decantation in settling vats was employed for separating solution and slime, a number of additional vats being erected for this purpose. During the time of these experiments, about thirty months, over $200,000 was recovered at a good profit.

FIG. 6.

The cyanide consumption was high, running about 7½ lb. per ton of ore and about the same consumption of lime. The 'holdover' was high; more than twice that of zinc-boxes. The anodes, whether iron or graphite, were always troublesome, recovery never checked within 10% of assays (these showing good extraction); while the whole process required extreme care in manipulation.

With a view to finding an economical method for handling the slime Mr. Oliver, early in 1907, began a series of experiments with filtration devices. The first drum filter was built April 1907, having a diameter of 20 in., and 12 in. long. This worked splendidly, as it was turned by hand, and never operated longer than ten or fifteen minutes without stopping. Assays showed excellent extraction, and the quantity of material handled showed the possibilities, if a machine of large size were constructed.

In June 1907 the first full working size filters were put in operation. Two filters with drums 6 ft. long and 6 ft.

diam. were built at this time. The filters as originally constructed did not work satisfactorily. The cake would not discharge properly and a thin impervious coating would form, preventing a new cake from building. When an attempt was made to remove the discharged or the barren cake by scraping, much difficulty was experienced with the tearing of the canvas. Different schemes were tried with varying success, until the plan of holding the filter-cloth in place by a wire winding was adopted. This method of construction solved the last difficult mechanical problem encountered. This experimental work was also done at the North Star mill. Early in 1908 four filters with drums 10 ft. diam. and 7 ft. long were built for the North Star cyanide plants. To make room for these machines, three of the agitators described above were removed, and the capacity of the remaining three increased by raising the sides 6 ft.; making the total height 20 ft. The central tube was not lengthened, and the spreader board was retained, as it gives a better distribution of the slime, and throws the heavy sand to the outer edge of the tank.

The accompanying illustrations show the six original agitators, three of which are still operating at the Central mill of the North Star Mines Co. The filters first installed are also working, not a single change in construction having been made. Further descriptions would lead to the discussion of present-day devices, so that these notes are submitted as an indication of a few of the difficulties encountered in the metallurgical advances here recorded. Through the courtesy of those responsible for the work described in this article, I have been permitted to examine correspondence and drawings covering the erection of the apparatus here illustrated and described.

Health of Miners

English and Colonial governments are engaged in closely studying health conditions in mines. In Queensland a commission was appointed to investigate several points in connection with the health of underground workers. The first field of inquiry was a general one relating to the conditions of work in relation to the health of the miners; the second related to the amount of pulmonary disease prevalent; and the third was a consideration of the expediency of preventing tuberculous subjects from doing mining work and of suitably compensating them for the loss of their employment. As regards general conditions, the commissioners are of opinion that the regulation of 1910 relating to efficient ventilation is sufficient for the purpose of maintaining a pure atmosphere and of reducing the temperature of the workings, except perhaps at Charters Towers, where the atmosphere in the deep mines is hot and moist. The law already allows inspectors to enforce the use of sprays or other allayers of dust in rock-drill operations, but the commissioners recommend similar powers in connection with the handling of ore at other points such as after blasting and during loading into skips. They also have many recommendations about drinking water, sanitation, etc. Their inquiries into the subject of pulmonary complaints disclosed the fact that fibrosis and tuberculosis are prevalent only to a limited extent and are confined to dry and dusty quartz mines, but that they are gradually on the increase. The recommendations in Part 1 of the inquiry will go a long way toward improving the conditions, but the commissioners are in favor of the additional drastic proposition under Part 3, namely, that men with lung troubles should not be allowed underground, that miners should be required to obtain medical certificates once a year to prove their immunity from pulmonary complaints, and that some sort of general insurance scheme should be inaugurated by the State to provide for such as are rejected. This part of the recommendations is of far-reaching importance, and will raise much discussion in other countries as well as Queensland. It stands to reason that in the confined space of the end of a drift or even of a stope, the proximity of a tuberculous subject must be a danger to the other workers. In Queensland and other countries it may be possible at a small cost to the community to check the spread of lung diseases by taking this drastic step, but whether the same policy can be adopted elsewhere without a great burden may be debated.

Giesecke Tube-Mill

Several of the leaders of the mining industry on the Rand have gone into ecstacies lately over the adoption of the Giesecke patent tube-mill, evidently under the impression that it was likely to revolutionize milling operations. It is even claimed that it may result in the total elimination of the gravity stamp, as by its use ordinary broken ore is easily reduced to such a fineness as to readily pass a 200-mesh screen. The mill is a German invention and has been hitherto principally used in the manufacture of cement. It may be described as a modified tube-mill some 24 ft. long, one-fourth of which is 7 ft. 6 inches in diameter and the remainder about 6 ft. in diameter. Its capacity is 50 tons of pulp, weight 68 tons, and when in action the mill revolves at the rate of 25 r.p.m., a 400-hp. motor being used to drive it. As far as can be gathered, it appears to be crushing 350 tons per day of ore broken previously into various sizes up to 6-in. cubes, with the result that 81% passes through 200-mesh, 6% over 200, 7% over 120, 5% over 90, and only 0.5% over 60-mesh. The method of working is to feed into the larger end of the mill, the coarse particles being confined to this until sufficiently reduced in size to pass through a screen dividing the large diameter portion from that with a 6-ft. diameter. The reduction is effected by steel balls varying in diameter from 2½ in. to 4 in. diameter in the large or breaking chamber, and down to 1¼ in. diameter in the grinding portion of the mill. As already shown, the pulp leaves the mill in a remarkable condition of fineness, the coarser particles being returned to the mill for further attrition. Water to the amount of less than a third in weight of rock treated is required, and as the mill is fitted with automatic lubricating devices, it seems to require a minimum of personal attention. The capital cost of such a mill is stated to be £6000 net, without including buildings, erection, or motive power. It is estimated to equal in capacity a 50-stamp mill, but so far no idea can be given as to the actual running costs. From what can be gathered, these are not lower than the lowest on the Rand—say, for instance, at the Roodeport United mine, where, with heavy stamps, a half-inch screen is used and 20 tons per stamp per day crushed, the pulp being finished by ordinary tube-mills at a total cost of 2s. 6d. per ton. Considering the reputed duty, the capital cost is low, but the question of most concern is the efficiency and the actual cost per ton treated. These do not seem to have yet been fully ascertained. When the design of the mill is taken into consideration, it is evident that the cost of maintenance will be large. At all events the experiments being made with the mill under local conditions by a committee of the Transvaal Chamber of Mines were for some time suspended because the steel balls used inside the mill became too worn to be effective, and the local agents and patentee did not seem to have any spares on hand to replace the worn ones. It would thus appear that the wear and tear was greater than anticipated, and to have over 20 tons of steel balls continually undergoing wear and tear must in itself constitute an expense far more than the total cost of running an ordinary tube-mill, not to mention the cyanide consumption this iron would cause. Other parts of the mill also do not seem able to stand the severe and prolonged strains thrown upon them. Before it can be said to justify the good opinions formed concerning it, some important vital alterations may become necessary. Even with such improvements it is doubtful whether the stamp-mill will be dispensed with, and as to reducing the ore to the necessary fineness of pulp at one operation, there are grave doubts among milling engineers here as to whether that is possible.

Iron rails make better sluice riffles than any other material and are laid lengthwise on a 4 by 6 scantling. The gold settles admirably in the space between them.

Sulphides of Iron and Their Genesis

By E. T. Allen

General Principles

*The genesis of ores is essentially a chemical problem. It involves in each individual case the formation of one or more minerals. Barring those rare instances in which the geologist may be able to observe a mineral in the actual process of formation, the conditions of formation have to be inferred from the data obtained by field observation, supplemented by what chemical information is available. At the present time our chemical knowledge of minerals generally embraces something of their behavior toward certain reagents, and often little, if any, more. Accurate data on the genesis of most of them is still wanting. This will have to be accumulated by actually forming the minerals in the laboratory and studying the conditions in systematic fashion. The questions of first importance in mineral synthesis concern, of course, the conditions of temperature and pressure and the composition of the systems in which the minerals have formed.

By laboratory study, certain limits to these conditions may be set, outside of which the mineral cannot exist, though in general the limits will be wide. Thus if it be learned that a certain mineral cannot exist above 450°, it is known only that the mineral in nature must have formed somewhere between this point and the lowest temperature which prevails in the earth's crust. It is quite probable that we shall be able in many cases to narrow this range of temperature by the study of paragenesis. Thus if we could determine the temperature limits of two different minerals which, on account of their intergrowth or otherwise, could be shown to have formed at the same time, it would be certain in that particular instance that the minerals formed inside the temperature range which is common to both. Thus far, we have been able to set these temperature limits for comparatively few minerals, chiefly those which are capable of existing in more than one crystal form. Here the temperature is often the most important condition determining *which* crystal form shall appear, and this characteristic of the mineral may be taken as an index of the temperature which prevailed in its genesis. In a similar way, the composition of original solutions has to a slight extent been determined, since it has been observed that crystal form is sometimes determined by the composition of the solution in which the crystal grew. For the determinations of pressure limits, there is at present no method.

In drawing inferences regarding the genesis of natural minerals from experiments in mineral synthesis, the investigator must be constantly on guard lest he mistake secondary for essential conditions. It is therefore necessary for the chemist who works in this field to keep in constant touch with the geologist.

The Sulphides of Iron

In this paper will be considered the application of some of the above principles to the mineral sulphides of iron which form one of the most important classes of the sulphide ores. The frequent association of these minerals, pyrite, marcasite, and pyrrhotite, with other valuable minerals of the sulphide group would indicate that the knowledge of the conditions of the genesis of the former might be applied to the latter as well. Also the association of the different sulphides of iron with one another have suggested several interesting problems of more particular nature which will here be considered.

Pyrite and Marcasite.—Pyrite and marcasite, the disulphides of iron, often occur in such geological formations as to lead to the belief that they were precipitated from cold surface solutions. Typical deposits of this character are those of the Mississippi Valley. Geologists have reasoned that these and similar deposits have been precipitated from sulphate solutions because surface waters have frequently been observed by them to carry ferrous and ferric sulphates which have formed by the oxidation of older deposits of pyrite or marcasite through the action of atmospheric influences:

$$FeS_2 + 7O + H_2O = FeSO_4 + H_2SO_4.$$

Observation has gone a step farther. Recent pyrite has been observed in wooden conduits, and on the twigs of trees in hot springs, and the fact that the same mineral occurs on coal, and sometimes associated with asphalt, has led to the conclusion that the ferrous sulphate has been reduced in some way by carbonaceous matter to FeS_2. A disulphide obviously could not be formed by simple reduction, but a more complicated process in which ferrous carbonate would be one of the products may be conceived. The following equation in a very imperfect way conveys this notion:

$$7C + 4FeSO_4 = 2FeS_2 + 2FeCO_3 + 5CO_2.$$

Omitting details, it may be stated that experiments which have been directed toward the formation of pyrite and marcasite through the agency of carbonaceous matter, have been entirely without result. A possibility of synthesis is suggested by the fact that pyrite and marcasite are commonly associated with other sulphides of a simpler nature, such as sphalerite and galena which are directly precipitated by hydrogen sulphide. Experiments have in fact shown that both pyrite and marcasite may be obtained by the action of hydrogen sulphide on ferric sulphate solutions. It is well known that ferric sulphate is directly reduced by hydrogen sulphide to ferrous sulphate with a simultaneous precipitation of sulphur, but it had not previously been noticed that the further action of hydrogen sulphide and sulphur on ferrous sulphate slowly gives rise to a dark precipitate having the composition FeS_2. This reaction, which may be represented by the equation: $FeSO_4 + H_2S + S = FeS_2 + H_2SO_4$, takes place even at ordinary temperature, though quite slowly. A microscopic examination of the product proves it to be distinctly crystalline, though the crystals are minute. If the reaction is allowed to go on at a sufficiently high temperature in a sealed glass tube, say at 200°C., the crystals grow large enough to measure, and it has been found that they are partly marcasite—a mineral which had not previously been made artificially. A method was devised by H. N. Stokes for the analysis of mixtures of natural pyrite and marcasite which we have used to great advantage in studying the laboratory products. It consists in the oxidation of the sulphides by a dilute solution of ferric sulphate. The products of the reaction are ferrous sulphate, sulphur, and sulphuric acid for both minerals, but the relative quantities of the products are decidedly different. Only 14% of the sulphur in marcasite is thus oxidized to sulphuric acid, the rest being precipitated as free sulphur, while 56% of the sulphur in pyrite is oxidized. It is thus possible to determine in any mixture of the two sulphides the percentage of pyrite and the percentage of marcasite. As was stated above, the action of hydrogen sulphide on a mixture of ferrous sulphate and sulphur gives in general a mixture of both pyrite and marcasite, and the application of Stokes' method has proved that there are two essential conditions which determine the proportions of the two. These are temperature and acidity. The higher the temperature during the reaction, the greater is the percentage of pyrite obtained. It is also true that the lower the acidity of the solution, the greater is the percentage of pyrite formed, until, when the solution becomes neutral or alkaline, the product is practically all pyrite. The equation above shows that it is not possible to maintain the solution neutral when hydrogen sulphide acts on ferrous sulphate and sulphur, for sulphuric acid is one of the products, but if we substitute suspended ferric hydroxide for the ferrous salt, the solution remains neutral (if we waive the question of the weakly acid nature of hydrogen sulphide itself). Another way in which we can command the same essential conditions is to heat pyrrhotite or ferrous sulphide with free sulphur and a water solution of hydrogen sulphide which contains a very little sodium bicarbonate. This solution dissolves and carries over the sulphur to the pyrrhotite, thus forming FeS_2 in a practically neutral solution, and the result is pyrite.

---

*Studies in ore deposition from the Geophysical Laboratory, Carnegie Institute of Washington.

An alkaline solution of sodium polysulphide precipitates from a ferrous salt an amorphous mixture of ferrous sulphide and sulphur, but these combine slowly under the influence of heat, and probably, even at the ordinary temperature, with the formation of pyrite.[1] These data enable us to draw some important conclusions relating to the formation of these minerals in nature:

1. We know that the mineral marcasite can be formed by the action of hydrogen sulphide on ferric sulphate solutions, or, what comes to the same thing, a solution containing ferrous sulphate[2] and hydrogen sulphide to which the air finds some access. If the solution contains as much as 1% of free sulphuric acid and the temperature is not above 100°, the product is all marcasite. It is also not improbable that pure marcasite can form at a higher temperature if the solution is still more acid. Now, these conditions agree strikingly with what we find about the genesis of marcasite from field study. It is always a surface mineral, presumably formed from surface solutions at *low* temperatures. It is also a matter of common knowledge that such solutions when they contain iron usually carry it in the form of sulphate, together with sulphuric acid, since they result from the oxidation of an older body of pyrite or marcasite.

2. We know that pyrite forms from solutions which are neutral or alkaline by the action of alkaline polysulphides on ferrous salts and by the action of hydrogen sulphide on ferric hydroxide. Both reactions are essentially the union of ferrous sulphide and sulphur in a neutral or alkaline medium. Coming again to the deductions from field observation, it is found that pyrite is always deposited by hot waters instead of marcasite, and also that deep veins which formed under comparatively high temperatures contain pyrite, never marcasite. Now, hot terrestrial waters are practically always alkaline, not only because silicates are hydrolized by hot waters with the necessary formation of an alkaline solution,[3] but because if a strong acid were allowed to act on rocks at the high temperatures which prevail in the depths of the earth's crust, chemical action would soon neutralize it by the decomposition of carbonates, silicates, and the like.

3. Pyrite and marcasite form together when hydrogen sulphide acts on ferric sulphate unless the percentage of free acid and the temperature are sufficiently low. The quantity of free sulphuric acid must be about 1% at 100° to insure the formation of marcasite free from pyrite, while at 300° it must be considerably more, if indeed it is possible to get a product free from pyrite at that temperature. Pyrite and marcasite are very commonly found together in nature—often in the same hand specimen and sometimes intergrown. Although in some cases the two minerals probably belong to different periods of deposition, it seems entirely probable, in view of the laboratory results, that in other cases they are contemporaneous.

Relation of Marcasite to Pyrite.—When marcasite is heated to a temperature of 450° C., under conditions which preclude oxidation, it changes to pyrite. Not only does its color become yellower and its density higher (the density of marcasite is 4.889, that of pyrite 5.02), but its behavior with a ferric sulphate solution proves conclusively that it has become pure pyrite; for while at the start the ferric sulphate oxidized only 14% of the sulphur of all the marcasite it decomposed, now it oxidizes 56%. In a comparatively simple way, it can be shown that heat is set free during this change, which proves, of course, that marcasite possesses more energy than pyrite. Pyrite cannot be changed directly into marcasite, that is, the change is irreversible and marcasite is what is called a monotropic form. The question of the chemical constitution of the two forms will not be discussed here, except that it may be remarked that they *appear* to be polymorphic forms in which the difference is one of crystalline structure rather than of a chemical nature. More important for the problems of ore deposition is the significance of the temperature at which the change occurs. It goes on at 450° very slowly and could not be detected at 400° in a period of four hours. It will be observed, therefore, that marcasite cannot have formed in nature above 450°, and any minerals which can be shown to have been precipitated at the same time with marcasite are subject, of course, to the same limitation. Pressure cannot be invoked to qualify this statement, for a pressure of several thousand atmospheres was found not to accelerate the change. We may also conclude that a paramorph of pyrite after marcasite would show that the original crystal had been subjected to a temperature the lowest limit of which lies somewhere between 300 and 450°, because at 300° marcasite crystals were found not to be changed to pyrite, either by acid or alkaline solutions.

Pyrrhotite.—This mineral can be readily formed by the decomposition of pyrite in hydrogen sulphide at temperatures above 575°. The higher the temperature is carried, the more sulphur is lost, and a product formed at high temperatures, say at 800 to 1100°C., takes up more sulphur when heated in hydrogen sulphide below that temperature. Although it is somewhat aside from the main purpose of this article, which is to discuss certain problems of ore deposition, it may nevertheless be of sufficient interest to remark in regard to the mooted question of the true chemical formula for pyrrhotite, that this mineral is really variable in composition, at the same time preserving its homogeneity; in other words, ferrous sulphide can dissolve a quantity of sulphur depending on the temperature like any other solubility. At 600° the maximum quantity dissolved is 6%. We may, if we please, represent such a solid solution by the formula $(FeS)S_x$.

Under the experimental conditions thus far tested (heating pyrrhotite in dry H_2S) a solution containing only about 6% of sulphur can be obtained, the addition of more sulphur changing the pyrrhotite into pyrite. The pyrrhotite of nature doubtless formed from solution, yet it is remarkable that the highest percentages of sulphur in the natural mineral range in the neighborhood of 6% dissolved sulphur, corresponding to about 40% of total sulphur.

Geological observations lead to the conclusion that vein forming solutions containing, doubtless, polysulphides, change pyrrhotite to pyrite, and phenomena are observed about contacts which lead to the belief that the reverse action, the decomposition of pyrite into pyrrhotite and sulphur, occurs. In the neighborhood of contact intrusive masses, where the sulphides of iron occur, pyrrhotite is found close to the contact where the temperature was highest and pyrite in the colder zones. It is commonly held by geologists that in nature pyrrhotite was formed from the same solutions as silicates like olivine and augite. The experimental difficulties are at present too great to permit attack of this question.

In conclusion, I wish to express indebtedness to J. L. Crenshaw, John Johnston, and Esper Larsen, in collaboration with whom the experimental data for this article were worked out; and to F. L. Ransome, W. H. Emmons, and especially to W. Lindgren, for geological data.

PYRITE is isometric ferric sulphide, FeS_2; marcasite is orthorhombic, FeS_2. The latter can be distinguished by its crystal form and cleavage.

---

[1] At the lower temperatures (100°) amorphous disulphide appears to be the first product.

[2] It is not essential that the sulphate be used; any other ferrous salt may be substituted.

[3] This of course postulates the presence of some alkali or alkaline earth metal in the rocks, but some of these metals are practically always present.

Perliminary Treatment of Water and Air in Cyanide Processes

By George A. James

Where water is used in other technical processes the importance of its analysis and proper chemical treatment is recognized, but it seems almost neglected in cyanide practice, where it stands in most vital relation. All natural waters contain impurities that have an influence on the results obtained by their use, and which can be corrected or improved by well known chemical and physical methods. There are various impurities found in natural waters, which have an effect on cyanide solutions, or ores; sulphates, chlorides, and nitrogen compounds of the various alkalis and metals, the carbonates and free sulphuric, carbonic, and hydrosulphuric acids. In addition to these, there is always organic matter in suspension and combined.

In cyanide practice many cases have occurred where preliminary tests have not agreed with later results. It is more than probable that such discrepancies can be traced to the water used. This indicates that the water should receive as thorough attention as the material to be treated, before a safe report on the results to be expected in practice can be given. A comparison of results obtained with distilled water, and the water to be used should always be made, and where differences are found, the reason should be sought and methods worked out for their correction. In experiments with waters, cyanide losses of two pounds have been found, and extraction losses of several per cent. My experience is that recovery in the majority of cases warrants the preparation of water before its use in any part of the cyanide process. The reasons for this can only be outlined, as the chemical reactions are obscure, and only a small part of the work necessary completed.

The first influence of water impurities is in preliminary washing of ore charges. The object of this is to remove soluble portions such as ferrous sulphate, copper sulphate, and free acid contents, which are destructive to cyanide solutions and retard percolation. The effect of ordinary water is to precipitate part of these impurities, very often adding other injurious compounds. Basic salts are formed (hydrates and carbonates), and as the sand acts as a filter medium, what organic matter there may be in the water is collected, to later destroy the leaching solution. Water containing acids may decompose iron compounds into a condition where they consume cyanide and form insoluble double salts. Sulphides are decomposed, resulting in sulphuretted hydrogen, another destructive agent for cyanide. This indicates the bearing water may have in this part of the process. In preparing stock solutions, annoying physical conditions and material loss of cyanide can be prevented by the proper treatment of water before the introduction of cyanide. Although my experiments have not reached the point where absolute conclusions can be drawn, they indicate that cyanide destruction by carbonic acid is far greater than generally supposed. Natural waters contain 0.5 to 122 grains of this per gallon, and excessive cyanide destruction may result from this acid alone. Water containing free sulphuric and hydrosulphuric acid are obviously unfitted for cyanide solution until properly corrected, and the same applies in a lesser degree where water holds an appreciable amount of suspended organic matter.

The physical condition is also important in considering the independent treatment of water before its use in cyanide solutions. Where water contains a large excess of calcium hydrate as protective alkali, calcium carbonate is precipitated wherever it comes in contact with carbonic acid in the air or other solutions. This precipitate clogs filter-presses and zinc-boxes. Where water receives previous treatment, a large part of this trouble can be prevented. In the final washing of charges of ore, the chemical contents of water may produce the re-precipitation of metals and a further loss of cyanide. In conclusion, it may be stated that almost all waters can be cheaply corrected, and even slight improvements would warrant this correction.

All air contains impurities destructive to cyanide. Cyanide plants often exist in neighborhoods where, in addition to the carbonic acid always present, admixtures of sulphuric, sulphurous, and hydrosulphurous acid can be found in large quantities; in fact, the roasting process may be part of such plants. The need of removing such impurities before using air for agitation or aeration can be seen. There are simple methods of doing this.

Making Use of Hydraulic Power

By Dennis H. Stovall

Practical use can often be made of the power afforded by the gravity-head pipe-lines of the hydraulic placer mine. Many surface properties in northern California and southern Oregon use power of this sort to operate dynamos, by which electric energy is furnished for night work in the diggings, as well as all the camp buildings. A small wheel, operated by a small 'tap' from the main line, does not reduce the pressure in the giants to any appreciable degree, and the convenience is worth many times the trouble and expense involved. A number of placer mines use power from the pipe-lines, or by penstock from the high-line ditch, to operate a sawmill; and by this means cut all the lumber needed for repairing flumes, constructing additional buildings, and for general improvement purposes. Sawmills can be had these days that are easily and quickly moved from one point to another, the entire outfit, including the power-wheel, being of such bulk as to allow packing on ponies or burros.

PORTABLE HYDRAULIC MOTOR.

A 'general utility' motor, operated by water from the pipe-line, is a handy contrivance. A motor of this type, built by a foreman, was seen on a southern Oregon property, and is shown in the accompanying illustration. It is employed regularly for a variety of purposes; it hauls the steel cable connected with the derrick and crane in lifting huge boulders from the diggings, and, by attaching a fly-wheel, it may be used in the machine shops and everywhere else about the mine that power of any sort is demanded. This portable water motor is very simple. It consists of an undershot wheel, with connecting shafts and pinions, and operating levers, all built on a substantial wooden frame. To this frame a drum is also attached, operating a cable. The adjustment for the cable drum is the same as that employed wherever cables are used. Water to operate the movable motor is taken from the main pipe-line through a fire hose; the latter being of such length as to allow several moves of the motor with only one connection on the main line. Any work round the mine that requires, or needs a donkey-engine and cable, can be done by this motor. The power is, of course, limited by the size of the water-wheel, and can be made as small or as large as the work demands.

Treatment of Mill Concentrate

By R. Lindsay

*As much attention has been given of late to the more careful collection and treatment of mill concentrate, a few notes on the procedure adopted at the Geldenhuis Deep, Ltd., may not be without interest. It will be understood that the following remarks apply more particularly to reduction works where operations are conducted on a fairly large scale, or to amalgamated mines working as sectional units over a reasonably limited area. The concentrate treated here results from the daily scrape from the mills at north, east, and west sections, also the big barrel residue from the respective mills; the concentrate retained on the plates with the amalgam being taken off together and transported to the central amalgam room by 11 a.m. in locked amalgam safes provided for the purpose. The scrape is then ground in barrels (a separate barrel being provided for each section) for 4 or 5 hours, and cleaned in the usual way over a stationary copper plate, the black sand settling in a tank 4 ft. 6 in. by 2 ft. by 2 ft., fitted with a baffle at 18 in. from the end adjacent to the plate, the heavy material grading 45% −200 (0.003 in.), settling behind the baffle; what remains on the farther side overflowing through a 2-in. pipe to a tank outside the building, the grading of the fine product carried over being 98% −200.

The first tank is cleaned out daily and produces about 250 lb. dry weight of concentrate, grading 45% −200 as already stated, and assaying about 30 oz. fine gold per ton. This product is then fed to a tube-mill 4 ft. 6 in. by 3 ft. 6 in., lined with 6 by 6 by 3 in. silex blocks and running at 26 r.p.m. using pebbles as the grinding medium. The product from the tube-mill, grading 98% −200, now flows into a batea running at 100 r.p.m. with a 3-in. stroke, a bath of 250 oz. of mercury being maintained therein. The batea acts most effectively as a trap, 7 oz. of mercury and 50 oz. of amalgam per ton being regularly caught. This 50 oz. of amalgam yields 11.28 oz. fine gold at a cost per ton of 3s. for power and 5s. for labor.

From the batea the concentrate pulp passes over a riffled launder and trap to the second tank, thus joining the overflow from the first tank. The overflow from the second tank passes into a third larger settling tank, the overflow from which is perfectly clear and is allowed to run to waste. The product in the last tank grades very fine, being all −200, and assays 12 to 14 oz. fine gold per ton, and represents about 5% of the total solids caught in the second tank. The concentrate from the big barrels in the respective mills is washed over a stationary plate in the usual way and is caught in a large tank divided into two by a partition crosswise in the centre. The product from the first compartment, amounting to 3.5 tons per month, grading 60% −200 and assaying 7.5 oz. fine gold per ton is transported to the central amalgam room every month and is tube-milled. The product from the second compartment, amounting to 2 tons per month, grading a little over 90% −200, and assaying 6.75 oz. fine gold per ton is transported direct to the reduction works at east section for cyanide treatment.

For cyaniding the finely ground concentrate, the conical tank designed by Andrew F. Crosse and described by him,[1] has been adopted and has proved most satisfactory. The tank, 7 ft. 6 in. diam. and 8 ft. 4 in. deep and having a content of about 122 cu. ft., treats comfortably 1800 lb. dry weight of material, and there is no trouble whatever in obtaining a clear solution for decanting, agitation with air going on meanwhile. As one would expect in treating material in so fine a state of division, the gold goes rapidly into solution, a charge assaying 250 dwt. fine gold per ton being reduced to under 30 dwt. after one hour's agitation.

The practice here is to agitate the charge with air for 12 hours before commencing to wash with 0.02% cyanide solution. At the end of 12 hours agitation the undissolved gold in the concentrate is down to 6 dwt. per ton, while the cyanide solution has a gold value of 56 dwt. per ton. Washing is then proceeded with at the rate of half a ton of solution per hour, 18% of the solution in the tank being thus displaced every hour, agitation going on meanwhile. The quantity of solution required for treating the 1800 lb. charge is 6 tons. This circulation on the Crosse principle with simultaneous decantation when washing, effects a considerable saving of time over settlement and decantation, considerably increasing the capacity of the conical tank. The washing is maintained for a period of 12 hours, making the total time of treatment 24 hours, at the end of which the concentrate residue assays 4 dwt. per ton, and the solution 0.08 dwt. per ton. This is at present the economic limit to which treatment may be carried. The cyanide consumption at 2.75 lb. of 120% KCN is rather high, due to the refractory nature of the material dealt with, but it has gradually been reduced from double the present consumption, and it is hoped that it will be still further reduced. Possibly there may be a useful field here for one of the various kinds of magnetic separators to eliminate fine iron.

The air for agitation is obtained from a little Ingersoll-Rand compressor; a $\frac{3}{4}$-in. branch pipe from it is allowed to enter a receiver fitted with a pressure gauge, just before entering the Crosse tank, thus allowing the consumption of air to be measured and the cost calculated. The consumption is 7 cu. ft. of free air per minute costing 5d. per ton of concentrate treated. The quantity of mercury recovered from the Crosse tank averages, up to the present day, only about 1 oz. per ton, thus showing the effectiveness of the batea as a trap as already mentioned. The total cost of transportation, grinding, and cyaniding is 26s. per ton as follows:

		Per ton.
Tube-milling	Transport and labor	8s. 0d.
	Power	3s. 0d.
	Pebbles	4s. 0d.
	Total	15s. 0d.
Cyaniding	Transport and labor	8s. 0d.
	Cyanide	2s. 3d.
	Lime	0s. 4d.
	Air	0s. 5d.
	Total	11s. 0d.
		26s. 0d. per ton.

The average value of the concentrate produced at the three sections of the Geldenhuis Deep is 16 oz. fine gold per ton, having a value of about £67. Taking the average residue at 4 dwt., and cost of treatment at 26s., the profit per ton amounts to £64 18s. The economic advantage of treating the concentrate on the mines where it is produced instead of selling it to customs works is apparent even when the basis of payment is as high as 94% of the gold content at 84s. per fine oz., less £6 per ton for treatment charges. Taking the concentrate at 16 oz. per ton as above, the profit on selling would be £56 13s. 4d., allowing 10s. per ton for bagging and transportation, the mines profit being thus reduced by £8 4s. 8d. The concentrate plant installed here toward the end of last year at a cost of £576, including royalty on the Crosse tank, has already handsomely paid for itself, gold to the value of over £2000 having been recovered up to the end of last May.

The U. S. Geological Survey has issued a report, covering the year 1910, giving the production of gold, silver, copper, lead, and zinc in the States of the eastern slope of the Appalachian range. Sixty-one gold placer mines produced 1524.54 oz. of fine gold, and quartz mines 6977.57 oz. or 78% of the total. The silver produced, some 91,595 oz., was a by-product only, being saved wholly in the refining of gold and copper. Copper production, nearly all from the Ducktown district of Tennessee, was 17,923,412 lb. The zinc output was 140,875,886 lb., of which 97% came from New Jersey. The valuation of the total mineral production is given by the report as $10,127,304.

Gold, Silver, Copper, and Lead Production of California

By Charles G. Yale

The mine output of gold, silver, copper, and lead in California in 1910 had a value of $27,020,405, according to figures compiled and just made public by the Mineral Resources division of the United States Geological Survey. The production of gold was $19,715,440; that of silver 1,840,085 oz., valued at $993,646; that of copper 48,700,756 lb., valued at $6,184,996; and that of lead 2,870,977 lb., valued at $126,323. These figures show a decrease in the output of gold, silver, and copper as compared with the figures for 1909, but a large increase in lead. The 1909 figures are as follows: gold, $20,237,870; silver, 2,098,253 oz., valued at $1,091,092; copper, 57,288,281 lb., valued at $7,447,476; lead, 1,502,597 lb., valued at $64,612.

There were 1079 mines producing gold, silver, copper, or lead in California in 1910, of which 564 were gold placer mines. Of the deep mines 485 were gold mines, 9 silver mines, 10 were silver-lead mines, and 11 were copper mines. Of the placer producers 168 were hydraulic mines, 72 were dredges operated by 41 companies, 139 were drift mines in ancient river gravels, and 185 were sluicing mines. Measured by the number of producers, as well as by the tonnage of metal output, deep mining decreased somewhat in California in 1910. Among the placers sluicing decreased also, but dredge and drift mining increased.

In 1910 there were 2,697,885 short tons of ore from deep mines sold or treated in California, with an average total recoverable value of $6.71 per ton, against 3,041,688 tons in 1909, with an average recoverable value of $6.41. Of the total recovered value in ores in 1910, milling ores yielded $10,005,190 in gold and silver; and smelting ores, $1,669,008 in gold and silver, $6,184,996 in copper, and $126,323 in lead. Placers produced $8,888,795 in gold, of which $635,498 was from hydraulic mines, $516,929 from drift mines, $7,550,254 from dredges, and $186,114 from sluicing mines, the yield from dredges alone being over 38% of the total gold output from all sources in California in 1910. Gold dredging has been of constantly increasing importance in California since 1899, when the yield from this source was $206,302. In 1910 it was $7,550,254. The total gold output by dredges in California to the end of 1910 was $40,318,775. The three great dredging fields are those of Yuba, Sacramento, and Butte counties, of which the Yuba county field showed an increased output of $730,557 in 1910, while the production from Butte county decreased $501,038, and that of Sacramento county decreased $164,542 for the year under review.

The following table gives the mine production of California by counties in 1910. Of the total gold placers furnished, $2,468,505 from Butte county, of which $2,389,235 was from dredges; $1,394,537 from Sacramento county, of which $1,369,594 was from dredges; and $3,199,952 from Yuba county, of which $3,172,476 was from dredges. Dredges also produced $191,900 in Calaveras county, $213,980 in Merced and Stanislaus counties combined, and $109,182 in Siskiyou county. Hydraulic placers produced $179,105 in gold from Siskiyou county and $328,154 from Trinity county. Drift mines produced $147,599 in placer gold in Nevada county and $151,743 in Placer county. Surface or sluice placers produced $29,700 in Plumas county, $22,339 in Siskiyou county, and $27,476 in Yuba county, and smaller amounts of gold in most of the other producing counties of the State.

The largest increases in gold production by counties in California were $347,461 in Amador, $80,815 in Mono, $122,363 in Sierra, and $734,408 in Yuba. The largest decreases were $499,288 in Butte, $292,806 in Calaveras, $78,885 in Mariposa, $126,752 in Nevada, $272,940 in Sacramento, and $310,077 in Tuolumne. The Mother Lode in Amador, Calaveras, Eldorado, Mariposa, and Tuolumne counties produced 1,170,497 short tons of ore in 1910, with a total recovery in gold and silver valued at $4,435,802, or an average of $3.78 per ton, against 1,338,160 short tons yielding $4,854,355, an average of $3.60 per ton, in 1909, or a slight decrease both in tonnage and recovery.

* Includes placer production.

Aluminum Production in 1910

Not over a generation ago aluminum was little more than a curiosity. It was worth $15 or more per pound, and its total production in the United States was less than a hundred pounds a year. A report on bauxite and aluminum for 1910, by W. C. Phalen, just published by the U. S. Geological Survey, shows a consumption in the United States in that year of 47,734,000 lb., valued at nearly $12,000,000. The price has thus dropped from $1 an ounce to about 23c. per lb. Mr. Phalen states that although aluminum has in recent years become most important, it is at present produced only from bauxite, a comparatively scarce mineral. He mentions a number of recently patented processes which show progress in the cheap extraction of the metal from the common sources of supply. As aluminum in its various forms, both pure and as an alloy, possesses many remarkable qualities, it may be welcomed as a coming metal of great utility. Should it become as abundant and cheap a metal as may reasonably be expected, the industry holds boundless possibilities. An alloy called duralumin contains 90 to 95% of aluminum, which at present prices would make it rather expensive, but it is claimed to have qualities as good as bessemer steel, although it is only about one-third as heavy as iron or brass. It possesses great hardness, even when annealed. Another alloy of aluminum and copper is said to be a good imitation of gold; it polishes readily and takes a high lustre and is well adapted to ornamental purposes. It is also highly resistant to chemical action and can be readily machined and rolled and drawn into wire. Aluminum may therefore have a wide future use, ranging from structural material to brooches and hatpins.

The growth of the aluminum industry in the United States in 1910 is shown in the following table:

PRODUCTION OF ALUMINUM IN THE UNITED STATES, 1883 TO 1910

Year.	Pounds.
1883	83
1885	283
1890	61,281
1895	920,000
1900	7,150,000
1905 (consumption)	11,347,000
1910 (consumption)	47,734,000

The industry in the United States is of equal importance with that in Europe. France, Switzerland, Germany, and Austria are the most important producing countries in Europe, though Great Britain is also an important producer.

Rocks as Reservoirs

The capacity of rocks to imbibe moisture varies with their physical structure. Most of the water in rocks occurs in pores and interstices, the larger part of the world's well water supply being derived from saturated porous beds, only a small part of it being obtained from caverns or large cavities. Practically all rocks, however compact they may appear to the eye, have interstices and small cavities in which water may be stored. The degree of porosity of rocks varies, being highest in open-textured sands, sandstones, gravels, and chalks, all of which have great capacity for imbibing water, and lowest in close-textured clays, slates, marbles, and granites, which have very small capacity for absorbing and transmitting water. Some rocks, however, such as granite, which in their original condition are almost impervious, become water-bearing through the development of fractures and crevices. The capacity of rocks for transmitting water is different from their capacity for imbibition. In certain fine-grained rocks the pore spaces are so small that they will not readily transmit water. Hence rocks like chalk or brick, which absorb water freely, transmit it slowly, whereas others with no greater total space transmit it readily. Sandstones, for instance, vary greatly in texture and consequently in their capacity for carrying water. (From report of United States Geological Survey.)

Cyanide Poisoning

The Mining Regulations Commission of the Transvaal has recommended the following measures to prevent cyanide poisoning and for treatment of men poisoned.

Preventive Measures.—(1) Provision of an adequate supply of wholesome drinking water about plants and assay offices, the same to be distinctly labeled 'Drinking Water'; (2) the replacement of strong cyanide solution used in the precipitation-boxes by water prévious to the zinc being handled; (3) the effective hooding of the dissolving bath in which the gold precipitate is treated, and the use of some form of mechanical agitator in order to eliminate the necessity of raising the hood.

Treatment.—It is recommended that boxes labeled 'Antidote for Cyanide,' with directions for use affixed to the lids of the boxes, should be kept in prominent and easily accessible parts of the cyanide plants. Each box should contain: A spoon and a metal receptacle to hold about 1 pint; one blue hermetically sealed vial containing 30 c.c. of 33% solution of ferrous sulphate; a white vial containing 30 c.c. of caustic potash, and one package of oxide of magnesium (light). The directions for the use of the antidote should be as follows:

1. Preparation of antidote. Quickly empty the contents of the blue vial, of the white vial, and of the magnesia package into the metal receptacle, and stir well with the spoon. This should be done as rapidly as possible, as the patient's chance of life depends on promptness.

2. Administration of the antidote. If the patient is conscious, make him swallow the mixture at once, and lie down for a few minutes. If the patient is not conscious, place him on his back and pour the mixture down his throat in small quantities, if necessary pinching his nose in order to make him swallow.

3. Incite vomiting. After the antidote has been given, try to make the patient vomit by tickling the back of his throat with a feather or with the finger, or give a tumblerful of warm water and mustard.

It must always be kept in mind that promptness of action is the first essential, as the poison acts quickly.

ELECTRIC FURNACES are furnaces in which the necessary heat or degree of temperature is produced or attained by means of electrical energy. The electric current is used in these furnaces solely for its heating or thermal effect, and either alternating or direct current may be used, but alternating is preferred because of its easier generation and management, capability of being procured from transformers, and absence of electrolytic effects. Electric furnaces render remarkable and highly valuable service to the chemist and metallurgist, for two distinct and unique capabilities; they can generate heat within themselves without the use of combustion and the consequent products of combustion to complicate the working of the furnace, and they can, besides, if desirable, produce temperatures absolutely unapproachable in furnaces using fuel, and thereby enable the carrying out of operations only possible at these extremely high temperatures. The upper limit of electric furnace temperature is simply the volatilizing point of carbon, the temperature at which the material of which the lining of the furnace is made, is boiled away. This is about 3700° C. or 6700° F. The simple statement that this is three times as high as the melting point of cast iron may give some notion of the enormous temperature possible. Besides high temperature, the efficiency of application of electrical heat to the useful purpose is usually high: in many cases 50 to 75% of all the heat developed can be usefully applied, as against 5 to 50% utilized in fuel-fired furnaces. The heating value or thermal equivalent of the electric current is perfectly definitely known; one kilowatt-hour will furnish 860 calories (3400 B.t.u.), which if applied usefully at 100% efficiency would bring to boiling and convert to steam 1.35 kg. (3 lb.) of water, or bring to melting and melt about 3 kg. (7.5 lb.) of cast iron, or 2.5 kg. (5.5 lb.) of steel.

August Production of the Goldfield Consolidated Mines Company

According to the report of J. F. Thorn, general superintendent, the total production of the Goldfield Consolidated during the month of August was 30,580 tons, containing $910,477, or an average of $29.77 per ton, of which 30,508 tons was milled with an average extraction of 94.75%, and 72 tons was shipped, of an average value of $65.21 per ton, the net recovery from all ore being $28.21 per ton. The total net profit to the company was $634,658, or $20.75 per ton. During the month 3744 feet of development work was performed. The total cost of mining, development, transportation, milling, office and general expense was $7.53 per ton, distributed as follows:

Mining:		
Development	$0.87	
Stoping	2.29	
		$3.16
Transportation		0.09
Milling		2.12
Marketing		1.03
General expenses		0.70
Bullion tax		0.36
Marketing ore shipped		0.03
Construction		0.04
Total cost of operation		$7.53
Miscellaneous earnings		0.07
Net cost per ton		$7.46

The 466 intermediate, between the 750 and 600-ft. levels and just south of the 428 stope, in the Clermont, has been extended 40 ft., and produced 265 tons of $20 ore. The 401-ft. raise between the 401 and 428 stopes, produced 54 tons of $150 ore. This raise is now 25 ft. above the back of the 401 stope, and is still in good ore. The 413 intermediate sill-floor has been considerably extended and has produced 1085 tons of ore, worth $45 per ton. The 706 intermediate, below the 1000-ft. level, is now in 4 ft. of $40 ore.

The 305-B cross-cut, about 100 ft. north of the main cross-cut from the shaft in the Red Top, produced 467 tons of $20 ore. Although not of a very high grade, this promises to be an important stope. Cross-cuts into the hanging wall of the 305-I stope exposed 6 ft. of $40 ore, which seems to extend the full length of the stope and should produce a large tonnage.

A new level is being driven at 150 ft. from the collar of the shaft in the Mohawk, to connect with some very good ore that has recently been discovered at about that depth, also to connect with the top of the big 111 stope. The 354 sill produced 380 tons of $15 ore. A new stope (300-X) has been opened up about 300 ft. north of the shaft, and produced 305 tons of $40 ore. The intermediate drift 80 ft. below the third level and south of the 354 stope, has produced 800 tons of $28 ore. The face is still in ore, and the walls are not exposed.

At the Laguna the Hazel shaft, which is 150 ft. deeper and about 400 ft. northeast of the Laguna, is being unwatered and will be connected with the Laguna workings, giving a level 150 ft. deeper than the present working-level.

The company is now engaged in constructing a plant to treat both the accumulated and current residue from the present concentrate-treatment process. Two Edwards duplex roasting furnaces, with 112 by 13-ft. available hearth-area, one Baker cooler, one 5 by 18-ft. tube-mill, together with the necessary bin room and conveying apparatus, will be contained in a steel building to be erected for the purpose. The additional tanks for collecting the roasted product and agitating in cyanide solution will be contained in an extension to the present plant. The gases from the roasters will pass through settling-chambers to a stack, situated high enough above the mill to avoid the effects of the fume. Tests show that 90% of the content of the residue can be recovered, with an annual saving of at least $80,000. The plant will cost approximately $70,000 and will be in operation by January 15, 1912.

American Institute of Mining Engineers

The A. I. M. E. excursion will leave Chicago for the Pacific Coast today, and meetings will be held in Los Angeles next week, followed by sessions in San Francisco the week after. The program so far as arranged is as follows:

EXCURSION TO SAN FRANCISCO

Saturday,	Sept. 30,	Lv. Chicago	8:00 p.m.	via A. T. & S. F. R. R.
Sunday,	Oct. 1,	Arr. Kansas City	8:50 a.m.	
		Lv. Kansas City	9:10 a.m.	
		Arr. La Junta	10:40 p.m.	
		Lv. La Junta	10:55 p.m.	
Tuesday,	Oct. 3,	Arr. Grand Canyon	8:30 a.m.	
Wednesday,	Oct. 4,	Lv. Grand Canyon	7:30 p.m.	
Thursday,	Oct. 5,	Arr. Los Angeles	2:30 p.m.	
		Dinner to visitors and guests, tendered by local committee.		
Friday,	Oct. 6,	A trip to the beaches.		
Saturday,	Oct. 7,	Automobile ride around Los Angeles and to Pasadena.		
Sunday,	Oct. 8,	Lv. Los Angeles	3:00 a.m.	via Sou. Pac. R. R.
		Arr. Santa Barbara	7:00 a.m.	
		Lv. Santa Barbara	11:00 p.m.	
Monday,	Oct. 9,	Arr. Del Monte	8:00 a.m.	
Tuesday,	Oct. 10,	Lv. Del Monte	4:00 a.m.	
		Arr. San Francisco	7:00 a.m.	

ALTERNATIVE

Saturday,	Oct. 7,	Lv. Los Angeles	9:20 p.m.	via Sou. Pac. R. R.
Sunday,	Oct. 8,	Arr. Bakersfield	7:10 a.m.	
Monday,	Oct. 9,	Lv. Bakersfield	9:00 p.m.	
Tuesday,	Oct. 10,	Arr. San Francisco	7:50 a.m.	

SAN FRANCISCO HEADQUARTERS, ST. FRANCIS HOTEL

Tuesday,	Oct. 10,	Afternoon: Opening session.
Wednesday,	Oct. 11,	Morning: Session.
		Afternoon: Leave by special train, Third and Townsend station, Southern Pacific, 2 p.m., for visit to Stanford University, returning to City by 6 p.m.
Thursday,	Oct. 12,	Morning: Session.
		Afternoon: Visit to University of California and other points of local interest.
Friday,	Oct. 13,	Morning: Leave for Folsom and Natoma to visit gold dredges. Luncheon at Natoma. Return to the City in time for dinner.
Saturday,	Oct. 14,	Morning: Military parade, San Francisco.
		Afternoon: Exercises at Golden Gate Park incident to beginning work on the Panama Pacific Exposition. Address by the President, W. H. Taft, the Governor, Hiram Johnson, and others.
		Evening: Street carnival, San Francisco.
Sunday,	Oct. 15,	Morning: Leave by special train from Ferry station for Bohemian Grove. Luncheon at Grove followed by concert. Return to City in time for late dinner.

EXCURSIONS FOLLOWING THE MEETING

Tuesday,	Oct. 17,	Japan excursion. Leave San Francisco, steamer *Manchuria*, 1 p.m.

Members Going East

		Lv. San Francisco (Via S. P. R. R.)	10:40 a.m.
Wednesday,	Oct. 18,	Lv. Ogden (Via U. P. R. R.)	2:30 p.m.
Thursday,	Oct. 19,	Lv. Omaha (Via C. M. & St. P. R. R.)	11:30 p.m.
Friday,	Oct. 20,	Arr. Chicago (Via C. M. & St. P. R. R.)	1:00 p.m.

During the time of the San Francisco meeting, October 10 to 17, the arrangements for the reception and transportation will be in charge of the local committee, and further details will be published later. Final plans will be perfected at the committee meeting today. Evening sessions at San Francisco will be arranged if desired.

Discussion

Readers of the Mining and Scientific Press are invited to use this department for the discussion of technical and other matters pertaining to mining and metallurgy. The Editor welcomes the expression of views contrary to his own, believing that careful criticism is more valuable than casual compliment. Insertion of any contribution is determined by its probable interest to the readers of this journal.

Battery Foundations

The Editor:

Sir—Referring to the discussion during last July in your columns on 'Concrete Mortar Blocks,' J. B. Fleming states, in reference to the battered form of block with anchor bolts set at an angle, installed by him in the mill of the Goldfield Consolidated mine, that to the best of his knowledge this is the first installation of this design of mortar block. I beg to call to his attention that there was published in the *Mining and Scientific Press* of May 11, 1907, a description of this mortar block, designed and installed in the Kuk San Dong mill of the Oriental Consolidated Mining Co. in 1905, by Charles D. Kaeding. I have been informed on excellent authority that the designers of the Goldfield Consolidated mill were aware of this at the time their plant was designed.

Henry B. Kaeding.

Siempre Viva Mines, Nicaragua, September 1.

Duty of Grinding-Pans

The Editor:

Sir—The enquiry of 'Kalgoorlieite' as to the duty of Wheeler pans, has remained long unanswered. He will find exhaustive data on the subject in R. Allen's 'West Australian Metallurgical Practice,' together with screening analyses with various feeds. In brief, the average duty of a 5-ft. pan is about 20 tons per day as a stage-grinder, or about 8 to 10 tons per day as a slimer. The power consumption averages 6 horse-power.

'Kalgoorlieite' is evidently surprised at the diversity of opinion existing in Mexico with regard to the efficiency of the grinding-pan, a diversity that needs some explanation in view of the fact that, at Kalgoorlie, pans are in general use and are considered thoroughly efficient machines. 'Kalgoorlieite' has my sympathy if he has been endeavoring to defend, in Mexico, the practice of pan-grinding, since he will never convince the majority. The main reason for this is that metallurgists in Mexico have nothing to learn with regard to tube-mill practice. The second reason is that pans have never had a fair chance there. The Wheeler pan, as used at Kalgoorlie, is practically unknown in Mexico. In its place is the standard amalgamating and grinding pan. The latter was in general use for intermittent charge-grinding in amalgamating plants before the cyaniding of silver ores was practised. In several cases it was adopted as a re-grinder, preparatory to cyaniding; but failure invariably resulted. Personally, I have done everything in an endeavor to coax even a moderate duty out of this type of pan, but all to no purpose. The general design was hopeless, the grinding surface was insufficient, the 'spider' taking up most of the room; the shoes and dies were much too light, and there was no satisfactory method of compensating for the loss of weight due to wear. The power consumption was in excess of that needed for an efficient pan of the same size, but the maximum output I could get on ordinary quartz ore and with the pan fitted with new shoes and dies and a Wheeler discharge was about 3 tons slimed per 24 hours, from 20-mesh.

The conversion of this type of pan into an efficient machine meant a complete renewal of everything, with the exception of the shell and gears, and, although I thought otherwise at first, I soon came to the conclusion that investment in tube-mills, and the scrapping of the pans, was the best course to pursue. To judge from the number of these machines that one sees on junk piles in northern Mexico, I was not alone in my experience or conclusions, and I gather that this is one of the reasons why grinding-pans are not in favor in Mexico.

A. W. Allen.

London, September 11.

The Economic Value of the Mint and Assay Service to the Mining Industry

The Editor:

Sir—Persistent rumors to the effect that the present administration contemplated surrendering the functions of its assay offices and refineries to private interests were silenced by the Director of the Mint, George E. Roberts, who, during his recent visit to the San Francisco institution, declared that its doors would not close. He informed the press that the reasons for the reduction of its force of employees from nearly 350 to 130 were the discontinuance of the coinage of Philippine silver pesos and United States gold pieces, also the installation of labor-saving machinery and other economies.

In 1902 the Director recommended in his annual report that the Government could save the wages of many employees, the cost of operating, wastage, and abrasion losses by discontinuing the coinage of gold. Over half a billion dollars in gold coin was then stored in the vaults of the Treasury Department, against which gold certificates had been issued. The banking interests had complained to him of their losses due to abrasion, and demanded bars instead of coin for foreign export. The wastefulness of coining eagles to ship to England, where they would only be melted and stamped as British sovereigns, was obvious to Mr. Roberts. Fortunately for a few hundred faithful employees, the good work of the coin-factories continued, as the pace-makers raced for records. In 1904, the banner year, the grand total amounted to $228,202,151 in gold and silver, and ₱12,552,629 for the Philippine Government.

A billion dollars in gold coin had accumulated in the vaults of the treasury in 1910, and this vast hoard of minted metal was deemed by Mr. Roberts in his last report to be a reserve sufficient for all practical purposes. In acordance with his ideas, Congress passed a bill authorizing the issuance of certificates against gold bullion received by the mints of the United States and stamped with its weight, fineness, and value. It was signed by President Taft on March 2, 1911. In August, the electrolytic refinery of the San Francisco mint began producing fine gold in the form of bright, glossy bars, 7 in. long, $3\frac{1}{2}$ in. wide, and $1\frac{1}{2}$ in. thick, weighing about 26 lb., and worth, upon an average, $7000. Upon their computed value certificates will be issued by the Treasury Department. The cessation of the coinage of gold was an undisputed economy, but the shake-up in the mint service which followed caused the spread of rumors, intimating that, in the interest of further retrenchment, the Government would turn over the refining of its bullion to private enterprise. But the Secretary of the Treasury has emphatically denied that the administration has now any intention of permitting this necessary public service to become a monopoly in the hands of the smelting trust.

Back of these smoke-clouds were the fires of the smelters, which long have burned with an eager desire to monopolize the refining of $150,000,000 or more which the mints annually receive. It is only natural that private interests should covet this prize, and that they should spare no effort to secure the 'rake-off' they would win from its refining. At the present time, approximately half of the bullion which the Government ultimately purchases is refined at private smelting and reduction plants, whose management is reaching out for the entire production of the precious metals produced in this country or tributary to it. If it were possible for certain influential financial organizations to induce the Government to abandon its refining-plants in the interest of a theoretical economy, they would probably not hesitate to eliminate Federal competition by resorting to short-cut methods peculiar to lobbyists. How an executive order or a legislative act that would put these institutions out of commission would 'help business." But, as this course is now neither feasible nor expedient, an attempt may yet be made to corner the gold and silver output of the country by cutting rates below the cost of refining. The adoption of Standard Oil tactics to cut throat competition, may only be successful if the mining operators can be cajoled to play into the hands of the precious metal monopoly as did the independent oil producers of unhappy memory. Any temporary losses which the trust might sustain while throttling competition would soon be recouped when it could purchase bullion upon its own terms and at its own assay value. Therefore, the private refiners regard the present scope of the mint service as a Socialistic intrusion upon their own field.

If the only function of the Government were merely to coin metal according to the demand, its usefulness would be much more limited. Its officials would only be concerned in receiving bullion of sufficient fineness to permit it being alloyed with copper and stamped with the face of Liberty. And now that the coinage of gold is suspended indefinitely while bars of fine metal are being manufactured instead, the interested smelters would fain be public-spirited enough to relieve the Government of the expense of refining its treasure. Such a situation would be ideal from the standpoint of the private companies, if the Treasury would purchase their fine bars at par, asking no such foolish questions as, "Where did you get it, gentlemen?"

For many years our Government has taken a paternal and fostering interest in the welfare of the mining and metallurgical industry. Its policy has ever been to protect the producers of the precious metals from the extortions of rapacious bullion-buyers. For this very reason the Government has established from time to time, assay offices at convenient centres where depositors, great and small, could depend on equal consideration and purely disinterested service. As the Government does not engage in the business of purchasing bullion for profit, the spirit and practice of this department is the refinement of the principle of the 'square deal.'

Just as the postage rates are fixed at their present low prices, so are the mint charges for melting, refining, and assaying (at the minor offices). Every endeavor is made to keep these costs at the lowest possible level. The Government has installed electrolytic refineries at Philadelphia, Denver, San Francisco, and New York during the past few years. These plants permit operating on much larger amounts of bullion than could be treated by the old-fashioned acid-parting processes. An additional advantage which the Government enjoys is its freedom from interest charges on the gold and silver undergoing refining operations. The private institutions, on the other hand, have to reckon on interest as a serious factor, which, in the end, is transferred to the producer's shoulders. In order to get business, the private purchaser must make some showing that will convince his customer that it is to his interest to patronize the private refiner. Frequently a higher assay report than the Government's certificate is the proper bait. This comes high, but they have to use it to land their prize. Of course, the producer has to pay for this artificial fly so skilfully cast. Usually the difference is made up by a heavier melting loss, or a 'revision upward' next time. The Government always credits the depositor with the metallic grains recovered from the slag, which often affords him quite an unusual advantage. No possible incentive for manipulating melting losses for profit can exist in the Federal service, where every effort is made to reduce such wastage to a minimum.

Whether the mint or the private refineries pay the best prices for various grades of bullion has long been an open question. Throughout the mineral districts one may hear many conflicting reports. Refractory gold and silver ores, mattes, concentrates, cyanide precipitates, and other metallurgical products in crude and bulky condition, must obviously be shipped to the smelters and reduction plants. From these sources are derived the bulk of the bullion which ultimately comes to the mint in the form of refined bars. The Government gives private enterprise a clear field in which to operate, as thus far it does not engage in industrial smelting operations. It even encourages this legitimate business by exempting bullion over 992 fineness.

The case is different with bullion in the form of crude gold or silver bars, dust, amalgam, jewelry, and plate. The mints have established brisk and healthy competition for metal in these conditions. A melting charge of $1 is imposed upon each 1000 oz. of bullion, or fraction thereof. Tariffs varying from ½c. an ounce on alloys of one precious metal with copper, to 1c. an ounce on bullion containing from 500 to 950 parts gold are collected to pay the cost of refining. During the fiscal year ended June 30, 1910, the mints and assay offices received a total of approximately $128,600,000 in gold and silver from all sources, foreign and domestic. The charges collected for parting amounted to but $242,249. The average cost to the depositor was less than one-fifth of a cent on the dollar. To what limit this infinitesimal figure might have been swelled if the producers of the Nation's wealth had been turned over to the tender mercy of a monopoly, it is difficult to conjecture. In some districts miners are stampeded to desert the Government by following the example of some big company, which may occasionally profit by a sliding scale of smelting charges, or the actual receipt of rebates. For example, in a region which produces $5,000,000 annually in gold and silver from a hundred mines and prospects, an influential company may obtain a wholesale rate on its output of a million dollars. Any child who has mastered the principle of discount will realize that the small producers ultimately pay for such rebates. If the remaining $4,000,000 can be brought to the smelter by the advertising effect of such an example, it is safe to bet that the small fry will be dealt with according to their apparent degree of business sagacity. In many instances good and discriminating judgment is displayed by mining men who send their bars recovered from free-milling ores and cyanide precipitate to the mint, while their more base and refractory products are shipped to the smelter. It is in the latter capacity that private enterprise performs its most useful service.

In many respects the mint and assay service is analogous in its usefulness to the postal department. It assays and refines bullion at a minimum cost, and provides a varied circulating medium according to the demands of the financial interests. In like manner does the postoffice extend its service to include savings banks, and perhaps, in the near future, the parcels-post. All of these duties intrude upon the industrial domain of private enterprise, but the trend of modern thought is along the more progressive lines of public service. The San Francisco mint is an institution that has proved a valuable asset to local business interests. Since 1854, a fabulous sum has been put in circulation by this agency, which otherwise would have been diverted elsewhere. An average of half a million dollars annually has been expended for supplies and wages, which have stimulated the ordinary channels of trade, while many millions have been invested by depositors in real estate and the industrial enterprises of this city.

In the light of recent political and economic developments, it seems hardly advisable for certain private refining interests to attempt to oppose the Government. Popular sentiment throughout the mining West would prompt progressive leaders to take radical action of a retaliatory nature. The question of the giving of rebates on refining rates might lead to some sensational disclosures. Those timid folk who still feel that the Government would come out second best in a tussle with a certain trust, may be cheered with the knowledge of a big stick in the hands of the chiefs of the Treasury Department. That beneficent bludgeon has the power of arbitrarily imposing a parting charge on bullion of less than 999 fine sufficiently high to take all the profits out of the refining of the same. This right of the Government may never be invoked, but should an emergency justify recourse to it this big stick of the Treasury could humble in a moment the most arrogant monopoly that ever raised its Hydra head.

HAROLD FRENCH.

San Francisco, September 16.

Concentrates

Most of these are in reply to questions received by mail. Our readers are invited to ask questions and give information dealing with the practice of mining, milling, and smelting.

AN ACID-PROOF INK which can be used with a drawing pen on zinc is made of 1 dram verdigris, 1 dram sal-ammoniac powder, and 72 drams lampblack, mixed with 10 drams water.

AN EXCELLENT cement for cloth or leather is made by melting together and mixing well the following ingredients in the proportion indicated: 16 gutta-percha and 4 india rubber, cut small; 2 pitch; 1 shellac; 2 linseed oil.

TO THOROUGHLY penetrate timber, designed for mines or other purposes, with creosote, the bark should be carefully and absolutely removed. A thin sheet of bark fibre will completely prevent the entrance of the creosote.

TO FIND the thickness of lead pipe required when the head of water is given, multiply the head in feet by size of pipe wanted, expressed decimally and divide by 750. The quotient will give thickness required in hundredths of an inch.

TO CLEAN scale from gray iron castings, pickle by immersing in water containing 1% of sulphuric acid, and let stand from two to three hours. Rinse in cold water and scour with sharp sand and a fibre brush, or with a coarse rag and the sand.

BISMUTH is not commonly found occurring in the native state, but sometimes the brittle silver-white mineral with a reddish tinge is found disseminated through the gangue in branching lines, or in grains and lumps. The most famous locality for native bismuth is Schneeberg, in Saxony.

JADE, or nephrite, was formerly supposed to be a cure for kidney diseases, both its names having that meaning. It is highly esteemed in China and India, where it is carved into ornaments and other objects of art. The bright green variety, called *fei-ts'ui*, and the grayish white are most highly esteemed.

A VERY hard putty is made by mixing a handful of burned lime with 120 grams of linseed oil, boiling it to the usual consistence of putty and allowing the plastic mass to spread out in a thin layer and dry in a place where it is not reached by the sun's rays. When required for use it is made plastic by holding over a lamp; on cooling it regains its previous hardness.

IN PREPARING bluestone for steel a few drops of muriatic acid will make the solution adhere to oily metal, and it can be used immediately without waiting for it to dry. Coat the piece to be coppered and wipe off the remaining moisture. To coat brass or bronze with this solution dampen a bit of waste, and dip it in cast-iron dust, then apply it to the pieces to be coated. This gives a fine coppered surface and any lines will show very plainly.

TEMPERING of copper is popularly supposed to be 'one of the lost arts,' but as a matter of fact is one that was never possessed to any higher degree than at present. It is safe to say that copper has never been tempered at any time by anyone, as it does not possess the necessary properties. Copper can be hardened in a number of ways; the easiest being to plunge the finished article into molten antimony or arsenic; the resulting alloy formed on the surface is exceedingly hard and brittle. Recent research in Mexico has shown that the tools there supposed to be made of hard copper were made by smelting mixed ores of copper, nickel, and cobalt; the resulting alloy, something like monel metal, was naturally hard. None of these old tools are of a quality equal to those which can now be made.

GOLD is sometimes very fine and is difficult to save by hydraulic methods. Many years ago a clean-up of an undercurrent of the Spring Valley Co. at Cherokee in Butte county, California, yielded $2600; this gold had been saved from material which had run through 2½ miles of sluices and over 19 undercurrents before being caught in the twentieth. Even then Chinese were at work upon the tailing.

CUPELS are ordinarily made of sieved bone-ash purchased from supply houses. The quality of this can usually be depended upon, but sometimes it may be too fine or too coarse, giving cupels that are likely to crack, in the first case, or too porous in the second. This may be remedied by mixing fine and coarse together, or by decreasing the pressure when working with fine material and increasing it for coarse. For ordinary work it is not necessary to mix any binder with the bone-ash, though any mucilaginous substance will make a stronger cupel. When such binders are used the cupel should be left in the muffle long enough to burn them off completely before adding the lead button, so the escaping gases will not interfere with the cupellation.

STEAM-SHOVEL records are of perennial interest, and those made on the Panama Canal are watched closely by engineers. The monthly record is now held by No. 257, which is a Marion, Model 91, working on railroad relocation work at Gatun. It worked in rock, with high bank, short cuts, and handled huge rocks that had to be loaded on 10-yard cars. There were many delays for backing and drilling, and in considering Panama records the eight-hour day and numerous holidays must be taken into account. The yardage handled by this shovel from February to July, inclusive, was as below, from car records:

February	60,210	May	72,060
March	69,600	June	65,310
April	61,100	July	60,310

This gives an average of 64,765 cu. yd. per month. From bank measurements the record figures a little less, 62,864 cu. yd., in itself sufficiently remarkable.

LINSEED OIL is generally regarded as the standard oil for mixing paint, but, owing to its high cost many other substitutes are used; in certain cases, indeed, other oils give better results. The essential characteristics of a paint oil are that it should mix well with the solid constituents of the paint, giving a mixture that works freely under the brush, and after being applied dries quickly to the proper degree. If it does not dry thoroughly it will be sticky and collect dust; if it dries too hard it will be inelastic and likely to crack. Only the drying oils can be used in paint, that is, oils which when exposed to the air become converted into hard inelastic substance. This is due to oxidation, which may be hastened by the use of japan and driers. Japan, a name now used for a variety of substances, meant originally a varnish which hastened the drying of the oil with which it was mixed. Driers are oxidizing substances, commonly oxides of manganese, and are commonly used by boiling with a small quantity of the oil, then adding to the total mass. A marked effect is thus produced by a small quantity, just as a little sour milk added to a large quantity will quickly sour the whole. Tung oil, made in China from the nuts of the tung tree, is highly regarded as a paint material, and fish oil, which is much cheaper than either of these, is much used for outside work, but must be thoroughly mixed with the proper dryer in order to secure proper hardening. The various animal oils do not dry quickly and should be used with caution when mixed with other oil. Bean oil, made from the soy bean of Manchuria, has recently attracted much attention, but its properties as a paint oil are not yet thoroughly tested. Whenever a painting job of any size is to be undertaken a careful study of the conditions to be met will often enable the work to be done at a much lower cost, and with much better results than if it is simply turned over to the local painter.

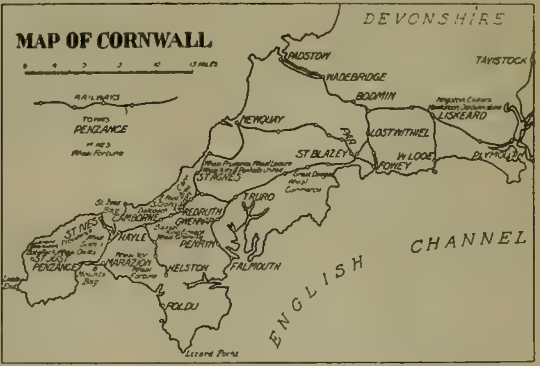
LONDON

East Rand Proprietary's Metallurgical Troubles — Miscalculations at Prestea Block A — Edward S. King's Reforms at Carn Brea & Tincroft

The London share market this week received a rude shock by the publication of a statement by the East Rand Proprietary to the effect that owing to unaccountable losses of gold in the extraction plant the profits would be less than estimated and the dividend reduced. A mistake in the methods of metallurgy on the Rand was unthinkable, and all sorts of wild guesses were made by shareholders and others. The announcement was not at all clear. It stated that for some time past there had been a serious shortage of gold from the cyanide works, as compared with the quantity called for by the assay calculations. By careful check it was found that sufficient gold had gone into the plant to provide the expected yield, and the managers clung to the hope that it would be found somewhere eventually. As time passed and the phenomenon continued, W. A. Caldecott, of the Consolidated Gold Fields, was asked to examine into the matter. In the latest report issued by the company it was announced that the yield for August was 51,093 oz. obtained from 197,333 tons, as compared with 60,000 oz. in July. Part of the decrease is explained by the absorption of gold in the reconditioning of the cyanide plant. If an improvement is not made shortly the profits will be seriously curtailed, and to a much greater extent than was expected when it was announced that the dividend for 1911 would only be 30 instead of 40%. The actual cause of this contretemps is not divulged by the managers, and some critics allege that the fault is in the mine and not in the mill. Such pessimists have some reason for this view, because on several occasions before ugly circumstantial reports had been in circulation, and had forced the board to make re-estimates of the reserve. Those intimate with metallurgical practice on the Rand are, however, inclined to think that it is the cyanide extraction that is at fault, and they point to the fact that this plant has been overworked. The whole of the stamps and tube-mills have been at work, though the full complement of cyanide vats has not yet been erected. It is their opinion, therefore, that gold has been re-deposited and lost. Whether the exact cause will ever be published is doubtful. For the benefit of American readers I ought to say that the East Rand Proprietary is a gigantic consolidation, effected in 1908, of properties belonging to the Farrar group. The producing mines at the time were the Driefontein, Angelo, Comet, and Cason. The capital is £2,500,000, and the capacity 200,000 tons per month. A few months ago Sir George Farrar announced that over 10,000,000 tons of ore averaging $6\frac{2}{3}$ dwt. per ton was ready for stoping; and judging by the area of the property the eventual life should be 30 to 40 years. It is legitimate to estimate the probable life in this way, for the work in the Cinderella, on the dip, is proving immense bodies of ore.

I wrote a few weeks ago about the Prestea Block A mine in West Africa, and announced that some of the stamps had resumed work, after the operation had been centred for a year or more on development. Now comes a remarkable announcement to the effect that the full battery of 110 stamps cannot be employed for over a year, because the capacity of the shafts is not equal to the demands of the mill. It had been estimated that by May of this year the output would be 30,000 tons per month, and it is a shock to find that somebody has made miscalculation. The directors state that only 15,000 tons can be raised per month, and that the higher figure cannot be reached until August of next year, when one of the new inclined shafts will be completed and equipped. Shareholders are quite mystified at this state of things, and wonder whether the former engineer in charge, or the new one, is at fault. The company was formed in 1903 to acquire from the Prestea Mines, Ltd., and the Appantoo Mines, Ltd., portions of the Essaman and Intermediate concessions, in the Prestea district near the Ancobra river, Gold Coast Colony. An additional block has since been acquired from the Appantoo Mines, Ltd., a total of 170 Rand claims.

In a recent letter I referred to the present position of the Carn Brea & Tincroft company, operating tin mines in Cornwall, and recorded that Edward S. King, late of Kalgoorlie, had been appointed manager, mentioning that this was one of the most important events in connection with Cornish mining that had happened for some years. A fortnight ago I outlined the results of the half year's work ended June 30. Mr. King faced the shareholders last week for the first time. Though an up-to-date and live manager, he is not an orator, and as he had not prepared a written speech, as most mining men find it safest to do, his impromptu remarks could hardly be described as fluent. But what he lacked in style of utterance was attoned for by the excellent common sense displayed. He had to criticize severely the old *laissez faire* method of mine management common in Cornwall, but was so pleasant about it that those who might have taken umbrage joined in his enthusiasm. I will quote the main points of his speech. He first described recent developments at the North and South Tincroft and was able to say that the ore reserves were sufficient to last for two and a half years. It is seldom or never that a Cornish manager will make an estimate of his reserves, and in fact Mr. King was only forestalled by a few weeks by Mr. Paull, of South Crofty, in a modern pronouncement on this subject. He then went on to say that this amount of work done per man was very small compared with that done in other parts of the world, and laid the blame on the unfair method hitherto in vogue of cutting down prices given to competent men when renewing contracts, and of increasing the price of men whose results were supposed not to give them a fair living. ("This system has made lazy men of we.") Another point upon which he laid stress was the absence hitherto of any adequate assay of the ore, concentrate, and tailing, and he condemned the old vanning-shovel assay to the limbo of forgetfulness. As regards the Cornish stamps, he found that their duty was only 13 cwt. per day per head, and that they were of the ancient type that had no anvil. He immediately placed granite blocks below and mounted iron 'bottoms' upon them, and the duty rose to 1 ton per day. Another serious question to be tackled was the scattered power-houses; at present there are five pumping shafts and eight hoisting shafts, the power for which is all independently generated. Such a system is hopeless in a property raising only 80,000 tons per annum. But perhaps his most scathing criticism was reserved for the Cornish system of keeping, or rather not keeping, accounts. Nobody can tell the cost of any individual item, such as development, power, roasting, or concentrating. The accounts are not analyzed and costs segregated. This is a point on which Mr. King properly insists, so that he can put his finger on the weak points. Mr. King is enthusiastic and is confident of eventual success even with the old rattle-traps of plant at his command. But he has a hard row to hoe, and the rehabilitation of this company will be more to his credit than he thinks. It is opportune to say that Mr. King is the first



outsider of high rank that has been appointed to the management of a Cornish mine and given a free hand. The other firms who have introduced London capital into Cornwall of recent years have appointed resident Cornishmen as managers. It is true that in one or two cases mining engineers of distinction have reopened old mines or have attempted to do so, but they have either been short of funds or have not been able to give personal attention to the work, so that their case is not quite the same.

KALGOORLIE, WESTERN AUSTRALIA

Ivanhoe East Lode Found in Great Boulder Territory.—Purchase of Transvaal Mine.—Miners' Phthisis Question.—Annual Report of Mines Department.—Production for July.

During the month a fine development was recorded by the Great Boulder company, in that the diamond-drill cut the Ivanhoe East Lode on the west boundary at a depth of 1480 ft., 1170 ft. north of the main shaft. The lode is 22 ft. wide, worth $40 per ton, and 6 ft. of it is in the Ivanhoe and 16 ft. in Boulder ground. The drill also cut the lode 5 ft. to the east of the west boundary at a depth of 1480 ft., 1250 ft. north of the main shaft. Here it is 15 ft. wide, assaying $46 per ton. This lode has been worked by the Boulder company through the Hamilton shaft on the north, where it was from 5 to 14 ft. wide, worth $14 per ton. A cross-cut is being driven toward the lode where cut. This development is important for both mines, and shows that an active exploratory campaign is being carried out.

The Oroya Exploration company has decided to close the option on the Transvaal mine near Southern Cross for $48,000 cash and an interest in any new company formed. The Oroya has been many months opening up the mine, and experimenting with the treatment of the ore, which is heavily mineralized with arsenical pyrite, and also some graphite. The solution of this problem will be awaited with interest by many, as its complex nature is known. It is rumored that oil flotation may be tried.

The annual report of the Mines Department, just issued, contains little that is fresh. Tin (black) to the amount of 471 tons worth $214,000 was produced; a decrease on the previous year; 34,369 tons of copper ore valued at $808,000; 262,166 tons of coal was raised, the output per man being 503 tons. There were 34 State mills at work, and 24 cyanide plants, also several slime-plants, and 2 tin-dressing plants. To date the mills have treated 784,407 tons of gold ore, yielding $17,800,000; and 45,492 tons of tin ore, yielding $320,000.

The Government has appointed a commission of five on the miners' phthisis question. They are: (1) to investigate and consider the causes of pulmonary fibrosis and tuberculosis among miners; (2) to investigate and devise means whereby such causes may be removed or their defects minimized; (3) to recommend the form which legislation should take; (4) to consider and report upon the results likely to follow from such legislation as would effect, (a) the economic working of the mining industry; and (b) the conditions of living and means of livelihood of workmen engaged in mining; (5) to consider and make recommendations upon the steps to be taken to provide employment for men who may be compelled to give up mining work on account of pulmonary diseases, or provide other means for their maintenance, when partly or wholly incapacitated. The present commission is the result of Dr. Crumpston's recent report on the prevalence of fibrosis, etc., in miners and surface workers on the mines. It is quite likely that the commission may suggest legislation along the lines followed in New Zealand and South Africa in creating a fund for the maintenance of affected workers, by a Government subsidy and a certain sum contributed from the mines.

GLOBE, ARIZONA

Production at the Miami.—Mill Records.—Progress on the Inspiration and Live Oak.—Shipments to Smelters.

The Miami Copper Co. is mining and milling 1700 tons per day, of which 200 tons is from the dump, 600 tons from development, and 900 tons from mining operations. Three and one-half sections of the mill are in continuous operation and the other 2½ sections are being rushed to completion. In the half of the fourth section now in operation an 8-ft. Hardinge pebble mill is being used for the fine grinding instead of the Chilean mills used in the other sections. If experiments prove satisfactory the other 2½ sections will be equipped with Hardinge mills. The Burch rolls, which were formerly credited with a high repair cost, are now said to be working satisfactorily. The salient feature of a lateral movement to one roll has been retained, but the mechanical application of the motion has been changed and the speed reduced without lowering the capacity. The mill is reported to be making a 75% recovery and to be producing 75 tons per day of concentrate averaging 42% copper. The average monthly production of refined copper is 1,800,000 lb. The concentrate is shipped to Cananea, whence the blister copper is sent to the refinery at Raritan, New Jersey. Five hundred and ninety men are employed, 300 underground and 290 on the surface, of whom 90 are in or about the mill. The Nordberg machinery in the power-house is running smoothly and a 75-hp. electric hoist is about to be installed at No. 2 shaft to replace the steam-hoist now in commission. This shaft is used only for men and timber, the ore being extracted through No. 4 shaft.

At the Inspiration, development is at a standstill, all underground work and all churn-drilling having been discontinued for the present. A damsite for a pumping station has been selected at Wheatfields, twelve miles from the mine on Pinal creek. Thirty men are working on a road at that place and a corps of engineers is making a survey for a pipe-line from the site of the proposed pumping station to the mine. Preliminary surveys for a millsite are in progress near the mine, and the engineers of the Arizona Eastern railroad are surveying for the extension of their track up Bloody Tanks wash and Live Oak gulch to a point near the Inspiration ground. At the Live Oak, the cross-cut being driven at the orebody from No. 1 shaft is about 550 ft. from the shaft. Shaft No. 2 penetrated the orebody at a depth of 705 ft. and is now at about 706-ft. depth and progressing rapidly. Five Star churn-drills are in continuous operation near the western end of the property. The ore is unusually deep at this end, from 600 to 1000 ft. of capping having been penetrated before the ore was reached. Twenty tons per day of silicate copper ore is being shipped to the smelter at El Paso from the dumps at the old workings. It is the intention of the management to ship 1000 tons of this ore. There is evidence that indicates that negotiations are pending for a consolidation of

---

*From old dumps. †Loss, due to capital expenditure in development and plant.

Live Oak with the Inspiration, but neither a confirmation nor a denial can be obtained. Such a merger would have many economical advantages.

The Keystone is operating a Star churn-drill on hole No. 36 about 500 ft. west of the shaft. The hole has passed through the granite porphyry and is now in the schist. Aside from this, there is no work going on at present, all underground development having been discontinued some time ago. Nothing can be learned as to the future intentions of the management.

SALT LAKE CITY, UTAH

Recent Developments at Park City. Progress at Cottonwood. Consolidations at Alta. Tintic News. Work at Bingham.

With few exceptions the mines of Park City have not shown much until depth was attained. The recent exception is the Barre-Coxe, which was organized only a few weeks ago. Its shaft has already cut two orebodies before reaching a depth of 50 ft. The shaft was sunk on a fissure, and ore has been found making into the bedded planes characteristic of a portion of the Park City district, where some of the greatest orebodies have been found. Two cars of ore have been taken out, assaying 30 to 42% lead, 20 to 38 oz. silver, and $1 to $2 gold. The management is preparing to drive an adit to intersect the fissure at greater depth, and explore the territory more economically than is possible with a shaft. The Silver King Coalition has practically completed the work of equipping the mine electrically, and will increase its output. For over a year the production has been about half normal, while the work of equipping the mine underground was in progress, but the management now says that during the next few months the shipments will be as large as ever. Several miles of 20 and 30-lb. rail have been laid, drifts have been straightened out and enlarged, the mine has been lighted with electricity, and other changes have been made toward the end of more economical and efficient operation. The Daly-Judge is making good progress with its development at depth since the drainage problem has been solved. If the stockholders of the Ontario and Daly companies ratify the proposed consolidation, it is expected that a more aggressive development campaign will follow at these properties. A number of the other Park City properties, old and young, are making encouraging progress, and the immediate future of the camp looks brighter than it has in several years. In the adjacent Cottonwood districts, the Utah Mines Coalition appears to have substantial claims to recognition as a mine, rather than a prospect. Last winter the property had a severe blow through a snowslide which did great damage to its surface improvements and caused loss of life. Within a short time after that, however, the operations began to show highly encouraging results, and now for several months the management has been blocking out orebodies and making shipments. Shipments are going on regularly, and arrangements are being made to continue them all winter. The Cardiff is another steady shipper, which has proved itself within the year. About 125 tons of high-grade ore per month is going from this property. Some of it is said to contain as high as 68.5% lead, 100 oz. silver, and 10% copper. The property has been explored to such an extent that the management has felt justified in driving a 2500-ft. adit, which is now in over 100 ft., to cut the veins at depth. A depth of 2000 ft. will be obtained in some portions of the ground. Drainage, as well as development of ore at depth are objects sought. Several other properties are reporting developments of more or less importance. On the Alta side several companies are preparing to consolidate to enable them to cope with water and pursue work to better advantage in other ways. Down in Beaver county, a new dividend-payer has appeared. This is the Moscow, which paid $8500 September 15. The Moscow is an old property in the Star district, but the present development campaign has been going on less than three years. Shipments have been made at intervals during this time, but the best ore began coming out during the summer. Six cars were marketed in August, averaging over $1400 per car. During the year the company has paid off $30,000 indebtedness and spent $6000 for water facilities, besides paying mining expenses, and it now has ore in sight to continue regular shipments for some time. The situation in the old Tintic district is somewhat mixed. The Chief Consolidated appears to be a comer among the newer properties. It is shipping regularly a good grade of ore, and is looked on as likely to continue to yield good reports. On the other hand, Colorado has cut its dividend from $60,000 to $30,000 for the quarter because the ore reserve is lessening and the company is conserving its cash for development work. The Opex, having failed to find the ore for which it was looking, has closed down. Uncle Sam has declared another dividend of $25,000, bringing the total to $495,000, or within $5000 of the capitalization, and the physical condition is said to be excellent.

The situation with the copper producers at Bingham has been pretty fully reported. The Utah Copper has completed its railroad and is pushing stripping operations at a tremendous rate and improving the mill so that it can increase its production heavily in the near future should it desire to do so. At present it is employing about 2200 men at the mine and is shipping something like 13,000 tons of ore per day. The Ohio Copper, still struggling with the general financing problem, has closed a contract with E. A. Wall to enlarge its mill capacity from 1700 tons per day to 3000 tons, materially reducing costs. Yampa is making a little money for the first time in its history. Utah Consolidated is pushing development vigorously in the hope of regaining some of its lost prestige. The Utah Metal Mining adit, which is to be 11,800 ft. long and is to connect several of the Bingham mines at depth with the International Smelting & Refining Co. plant at Tooele, is nearly half completed, and work is now going ahead from both ends. It should be finished inside of a year. Some of the smaller companies operating in Bingham are having trouble to get the necessary funds for development, but the camp as a whole is prospering.

NEW YORK

Depression of Share Markets.—The Copper Situation.—Reorganization of Arizona Commercial.—Channing on the Finlay Report.—General Development Enters Lake Superior Field.—Nevada Utah.—Porcupine News.

The monotony of chronicling the constant decline of the market is as nerve-racking as trying to keep step with a bounding upward market, which uses each advance gained only as a stepping stone to reach still higher planes. Since August 1 the decline has been steady and uninterrupted, culminating this week in an attack on both the common and preferred shares of the United States Steel Corporation, adding to the already gloomy atmosphere a spirit of foreboding of what ensuing tomorrows are to bring. Political factors are deemed of first importance. The dissolution of the Steel Corporation and the International Harvester Co., either voluntarily or involuntarily, are confidently expected, and Wall Street, outraged in all its traditions, crimped in income by lack of business, apparently forsaken by the leaders so often acclaimed as saviors, exasperated, must stand and watch the issues which have provided no small share of the activity of past years, wiped off the board as outlaws. Wall Street has no philosophy for the present crisis, and to it the very firmament is falling. Steel was Morgan's triumph and it is to be declared without the pale. The Goths and Vandals are defiling the innermost shrines of Wall Street's temples. The degradation is complete. This week saw two 'million share days', the first of the current year, and they brought no comfort. All attempts at new enterprises in any public way are for the time completely abandoned. The situation abroad is equally depressing. There are not a few voices that can be heard to argue that it would be much better for the situation to come to a violent break in any quarter and so relieve the present intense strain, rather than prolong it.

In the copper situation the trend of affairs abroad is the dominating factor. The export demand has saved the copper market during the last year, and it must continue to draw heavily upon our production unless we are again to see a surplus rapidly accumulating. The industrial inflation in Germany constitutes an admittedly weak span in the world structure of commercial credit just now, and desperate efforts are being made to get back to earth once more without loss or harm. The development of devices in use in making copper has been so rapid and so remarkable, the enlarged scale upon which copper mining is now conducted is so gigantic, that it is small wonder that the industry is in something of a state of confusion. The world's production is increasing so rapidly that consumers are unable to take any aggressive position in the buying of copper, and while the volume of accumulated stocks is watched as a barometer, there is a great deal more keen analysis made of the situation than a mere review of the monthly published figures. The year 1907 was something of a date line in copper. Since the panic prices of that year the metal has been struggling for a normal basis, and during that time production has increased some 855,000,000 lb. as compared with the three years preceding. It is the knowledge of these conditions that causes manufacturers to ignore, as they have during the last three months, a smaller surplus. The needed correction is not curtailment of output, but conservation of ore reserves. The pine barrens of the Southern States ought to be an object lesson for copper producers. Once, and that but a short time since, considered inexhaustible, now they are nearly gone and the turpentine camp has taken the place of the sawmill. By way of example of the development of huge output, Utah Copper broke all records for the month of August with 9,010,669 lb of copper being 1,455,262 lb. greater than the previous high record month of May 1910. Nevada Consolidated, on the other hand, suffered somewhat for lack of water, and production was cut down to 5,249,514 lb., a little below the output for any month so far this year except February.

It is characteristic of periods of liquidation that attempted reorganizations meet with many snags and obstacles. The merger of the Arizona Commercial and the Superior & Boston, a reorganization of the former at the same time, was hailed as a completed move a week or more ago, only to be set aside now for an independent reorganization, with Charles S. Smith, vice-president of the Old Dominion, as the new head for the Arizona Commercial, which is to be made into a new company of 300,000 shares, par value $5; the bondholders to exchange their $1,000,000 in bonds for $700,000 (140,000 shares) in stock; the present shareholders to exchange present holdings (120,000 shares) for the same amount of new stock, but to pay in $3 per share, all of which will leave the new Arizona Commercial with 40,000 shares of stock as a treasury reserve.

The discussion of the Finlay report on the mines of the Lake Superior region continues to hold attention in Boston. It is conceded that the most important part of the Finlay report lies in what is said concerning the exhaustion of the Calumet & Hecla and his comment that no mines have so far been developed to replace this chief source of production. Inasmuch as J. Parke Channing was the principal engineer in the making of the original appraisal of the Lake properties, his comments on Mr. Finlay's conclusions are of particular interest. In a recent interview, Mr. Channing said: "The Finlay report took into consideration nothing more or less than the immediate valuation of the mines examined for the purpose of taxation. There is no district in America where more possibilities exist for the finding of new lodes and new mines than at Lake Superior. There is no doubt whatever that the older mines like Quincy, Calumet & Hecla, and Hecla proper, and Tamarack have seen their best days as producers, but on the contrary there are new mines like the Copper Range, Ahmeek, Superior, Hancock, and others, all virgin and new producers, and developed to date at only shallow levels. Then in the vicinity of the Lake mine and the Indiana, great possibilities exist of finding copper deposits. As a whole, therefore, the Lake Superior section bids fair to maintain for many years to come approximately the same output as in the past, the newer properties taking the place of the older. There is a great area thirty miles long that must be considered as mineral territory only partly explored today."

It is altogether natural that the trend of opinion in Boston should be against the porphyry coppers. Boston is reluctant to admit the domination of the red metal industry by the steam-shovel coppers. The low costs reached by properties such as Utah Copper and Nevada Consolidated and confidently anticipated in the cases of Chino, Ray Consolidated, Miami, Inspiration, and others of this class have in the eyes of a part of the public robbed the deep-level vein mines of their attractive possibilities. Along this line a leading Boston copper man argues that "year in and year out the cost of production by the vein mines will compare favorably with the porphyries, particularly if anything like a uniform method of accounting is used. A porphyry mine is an entirely different proposition from a vein mine when it comes to this item. Most of the porphyries start with practically all their ore developed, and the tendency is to include in costs all expenses of mining, concentrating, etc. On the other hand, the vein mines develop as they go along, which expenses are charged to copper cost. In the case of the porphyries development expense has been capitalized and unless proper depreciation charges are made the cost of the porphyry production is seemingly much lower than conservative accounting would indicate; the porphyries are not going to revolutionize the copper business either as to price, output, or cost of production."

Mr. Channing's work in the Lake regions is evidently to result in something more than mere discussion of the conclusions arrived at in examinations. It is now stated that the General Development Co., the Lewisohn organization, which controls the Miami, the New Keystone, and other important copper properties, is negotiating for a group of properties adjoining the Isle Royale and south of the Quincy and the Hancock mines. The lands in question aggregate some 1300 acres and consist of the south side of Naumkeag, the Dakotah, and the Montezuma, and some lands of the St. Mary's Mineral Land Co. The land is thought to carry the southern extension of the Pewabic and the Hancock lodes. At the moment the negotiations are waiting the return of Mr. Channing who is at the Miami, in Arizona, on an inspection trip. The Street is inclined to attach a little significance to the entrance of W. E. Corey into copper mining circles and his trip through the Southwest and into Mexico, coming just at the time when the troubles of the Steel Trust seem to have culminated in a historical market smash. It has been rumored that Mr. Corey went heavily short of steel before his retirement was announced. It is quite evident that Mr. Corey is not now concerned with the troubles of the Steel Corporation and his serious intentions as to copper as a future field for his activities are indicated by his trip; on which he travels in company with John D. Ryan of the Amalgamated, R. L. Agassiz, vice-president of the Calumet & Hecla, and William D. Thornton, president of the Greene-Cananea. After a thorough inspection of the Greene-Cananea, the party will visit several of the principal mining centres of Mexico.

Nevada Utah's troubles seem to be without end. The last recent attempt to effect a merger of the properties of the Pioche camp has wound up in a tangle of litigation involving E. R. Woolley, the Pioche Amalgamated Mines Smelting Coporation, the Pioche Consolidated, the Nevada Utah, L. Vogelstein & Co. of New York, and the National Bank of the Republic, of Salt Lake City.

The announcement made some weeks ago that the Nipissing Mines Co. is to undertake important exploration at depth, to sink a shaft to the 1000-ft. level to settle the much mooted question of the Cobalt formation is now flatly contradicted, and neither drill nor shaft is to be sent down nor any sinking done save as mine conditions warrant. Nipissing's extreme depth is about 300 ft. A hydraulic plant to be used in removing overburden was erected last spring, but delays have intervened until it will not be put into commission until next spring. It is anticipated that this hydraulic work will greatly facilitate prospecting.

General Mining News

ALASKA

Juneau

The Alaska United G. M. Co produced in the month ended August 15, free gold, base bullion, and sulphides valued at $48,186 from the Ready Bullion claim, and to the value of $47,040 from the 700 Foot claim. From the former 18,568 tons of ore was crushed and 430 tons of sulphides saved. From the latter 19,532 tons of ore was crushed and 379 tons of sulphides saved. The realizable value of the total production was $47,704 for the Ready Bullion claim, and $46,590 for the 700 Foot claim. On the former 259 ft. of development work has been done, and on the latter 322 ft. The 20 stamps added to the mill on the latter property have been in operation during the month.

Prince of Wales Island

Samuel Lichenstadter, president of the Mt. Andrew Iron & Copper Co., died of heart failure at Ketchikan, Alaska, September 20. He had been at the mine, which is located on Prince of Wales Island, for some weeks prior to his death and was apparently in the best of health.

ARIZONA

Cochise County

(Special Correspondence.)—The Copper Queen Con. M. Co. has taken options on eight mining claims and five millsites in the Old Hat district. The price named is $50,000, of which $1800 has been paid. In one year $16,800 is to be paid, and the balance of $31,400 in two years. The properties are the Copper Trident, Grant, Copper Era, General R. E. Lee, Copper Head, Marble Peak, Tunnel Site, and Wedge mining claims, and the Centennial, Beautiful Snow, Giant, Lawton, and Lunton millsites. The Copper Queen company is to have full possession of all property excepting the residence of R. N. Leatherwood. An amendment also has been filed to the option from William Reid on the General Grant claim, extending the time of the first payment of $5000 to August 15, 1912.

POWER PLANT OF THE COPPER QUEEN.

Douglas, September 25.

Gila County

The directors of the Live Oak Dev. Co., at a meeting in Boston recently, elected the following officers: Henry B. Hovland, president; J. D. Clark, vice-president; Harvey Smith, secretary; J. B. Hardon, assistant secretary; D. L. Fairchild, of Duluth, treasurer.

Security holders of the Arizona Commercial Copper Co., at a meeting in Boston, decided to attempt reorganization of the property as an independent enterprise. A committee of six, representing both classes of securities, appointed by the meeting's chairman, S. R. Pearman, is to draw up a plan for the reorganization of the company. Consolidation with the Superior & Boston has been proposed.

At a meeting of the stockholders of the Warrior Dev. Co. in Globe, September 12, a new board of directors was elected as follows: S. R. Kaufman, Marquette, Mich.; J. C. Rotterhaus, D. L. Fairchild, E. C. Congdon, Harvey P. Smith, and H. B. Hovland, all of Duluth, Minn.; and M. E. McCarthy, of Globe. It is not known whether the option on the Black Warrior mine, owned by the Warrior Copper Co., will be exercised.

The Inspiration mine, according to late reports, has ore reserves, averaging 2% copper, of 26,569,400 tons developed, and 81,300 tons partly developed. Future effort, it is stated, will tend toward preparing the ore reserves for mining and treatment rather than toward developing additional tonnage. Under the direction of C. H. Repath, engineers are making plans for the new 5000-ton mill.

Pinal County

The Ray Con. Copper Co. is about to ship its ore to El Paso, where the reverberatory-furnaces of the A. S. & R. Co. are practically completed, according to late reports. Since July the ore has been shipped to Aguascalientes.

CALIFORNIA

Butte County

(Special Correspondence.)—Some $20 gold ore has been opened in the Clipper Mills mine. The vein is developed by means of an adit for 100 ft. If the vein continues along such favorable indications, the owners will buy machinery to work the property on an extensive scale.

Sierra County

(Special Correspondence.)—A gasoline engine generator set for electric hoisting and pumping is now being erected at the Monte Cristo gravel mine near Downieville. This mine is showing up well.

The construction of a water-driven compressor has been completed at the Kate Hardy mine near Forest and driving in the lower adit has been started. With a total of only 525 ft. of prospect adit along the foot-wall, this mine has an actual mint record of $28,000 in specimen gold ore extracted. Very little stoping has been done, and that only in a narrow layer adjacent to the foot-wall. The balance of the vein, 20 ft. wide, has not been explored. Samples taken along the outcrop indicate an ore-shoot 300 ft. in length assaying $12 per ton exclusive of high-grade ore.

The electric equipment for the Omega gravel mine near Forest has been installed, and work is being carried ahead on an extensive scale. The main adit is being pushed ahead up the centre of the channel, at the same time cross-cutting to define the latter, which is about 200 ft. wide. This company controls one mile of channel. The gravel will average $1.75 to $2.75 per car exclusive of rich 'bunches.'

Surveys and estimates are being made for the installation of electric power at the North Fork mine near Forest.

The rich ore still persists at the Red Star mine near Alleghany. About $80,000 has been taken out during the past month. Ore in the vicinity of this shoot mills $150 per ton. On the same vein at the Tightner mine in the lower adit, specimen rock has also been found. The latter discovery now establishes two definite shoots of high-grade ore. The 10-stamp mill on this property is about completed.

Alleghany, September 23.

Tuolumne County

(Special Correspondence.)—Steps are being taken for the resumption of operations at the Draper, near Soulsbyville. Unwatering the mine is now in progress and should be accomplished in another two or three weeks. R. A. Nicholls is again superintendent.

The eight men operating the Soulsby under lease are said to be well satisfied with results thus far, though up to the present time the mill has been run only at irregular intervals.

A company has taken under bond the Uncle Sam mine, at Arastraville, and will begin operations in the near future. The property was unwatered for examination and consequently but little remains to be done before actual work can be commenced.

The mill at the Sunnyside, south of Tuolumne, will be in operation within a few days. The ore will be taken from a shoot 5 to 7 ft. wide which averages $7 per ton.

The Jim Lyons mine, in the Confidence district, has been bonded to A. H. Russell, of San Francisco. According to report the price to be paid for the property is $75,000. It is still the belief of some that the mine is the one from which Jim Lyons, a notorious character of the early days, took out a great amount of gold. The ore is of a very high grade, assaying from a few dollars to several hundred dollars per ton. The owners endeavored to sink a deep shaft on the property, but found this impossible without the proper machinery to handle the heavy flow of water encountered.

Tuolumne, September 24.

COLORADO

Gilpin County

(Special Correspondence.)—A vein of ore 6 in. wide that assays $100 per ton in gold and silver, has been uncovered on the 210-ft. level of the Maine mine. The same vein is showing on the 310-ft. level. L. H. Leber is manager. A carload shipment from the London mine in the Twelve Mile district made last week brought $32 per ton net. Large orebodies are showing throughout the various workings. A hoist is being erected over the Corydon mine. The property is owned by Henry M. Teller, ex-senator, and was a good producer a number of years ago. A gold 'retort' weighing 57.15 oz., which sold for $17 per ounce, was deposited with the Rocky Mountain bank. The gold was secured from ore from the U. P. R. mine. A shipment of ten carloads of ore from the Topeka mine made a few days ago brought 16.75 oz. gold, 16.60 oz. silver, and 7.15% copper, a total valuation of $334.61 per ton. The ore was taken from the 1400-ft. level.

CENTRAL CITY.

Central City, September 20.

Lake County

It is reported that a large combination dominated by the Central Colorado Power Co. is to undertake to unwater by 'coöperative pumping' the mineral area known as the 'downtown' district of Leadville. It is believed that the managers and owners of the properties involved will assist in the project. The plan includes the placing of a large pumping-plant in the shaft of the Penrose mine, of which the principal owner is J. F. McDonald. A. F. Bohn, postmaster of Leadville, is one of the leaders in the project.

Teller County

The Dante No. 1 soon will have a 100-ton cyanide mill, according to an announcement by A. E. Kelso, who is associated with some Colorado Springs men. The equipment for the plant was purchased at Denver.

Newspaper reports state that the recent discovery on the Colorado Boss property by J. R. Lewis is now believed one of the largest ore-shoots found in the camp this year. The lowest assay of any grab sample is said to be $108. The mine is on the south slope of Gold hill.

IDAHO

Idaho County

W. W. Gifford, of the Hydraulic Placer company, operating on the Salmon river, 15 miles east of its confluence with the Snake river, said on returning from the diggings that gold washing will begin early in October. The pipeline is completed and the two big giants are ready for use and only 200 ft. of flume remains to be installed. The apparatus is designed to wash 1000 yards of gravel daily.

Shoshone County

The Hecla Mining Co. brought its total disbursements to $2,290,000 by the payment of its ninety-ninth dividend of $50,000, at the rate of 5c. per share on September 21. Of this, $180,000 was paid this year. The mine, which is situated at Burke, has ore reserves to maintain the present rate of production for two years, it is asserted.

The cross-cut adit being driven by the National Copper M. Co. to develop its property above Mullan, is in 2400 ft., or a little more than half the distance planned.

The C. & R. Mining Co., working a property of the same name adjoining the Hercules mine in the Coeur d'Alene district, has erected a compressor and gasoline engine to expedite the driving of a lower adit, now in 200 ft. The adit, when completed to the vein, will be 900 ft. in length. It will tap the vein at a depth of 340 ft. under the No. 2 adit.

The Amazon-Manhattan group of eight patented claims on the west side of Carbon creek in the Sunset district of the Coeur d'Alene, nine miles north of Wallace, has been secured by William T. Tracey of Galesburg, Ill., who has engaged Patrick Burke, until recently manager of the Jack Waite mine, to develop the property. About $300,000 is involved in the deal. The property, which has been owned the past nine years by the estate of Barry N. Hillard and his heirs, Horace M. Davenport, Charles M. Asp, and Ben Stanley Revett, the last of Colorado, has two distinct veins, both having good ore from the grass-roots. They are about 100 ft. apart on the surface, and dip toward each other. The Amazon has the largest orebody, while the Manhattan has a higher grade of ore.

MICHIGAN

Houghton County

Drill-hole No. 15 of the Mayflower M. Co. has passed through two promising copper-bearing formations. It is down over 1350 ft. Old Colony No. 9 drill-hole has been discontinued at a depth of over 800 ft. What is thought to be possibly an extension of the St. Louis vein was discovered, but contained no copper in commercial quantities.

The Mohawk M. Co., in August, made a new record for output—1,134,684 lb. of refined copper. The recovery per ton of ore was 15.53 lb. of refined copper, the lowest recovery since last March when it was 13.88 lb. The production in the first eight months of 1911 was 7,927,971 lb., against a production of 7,358,814 lb. of refined copper in the first eight months of 1910.

MISSOURI

Jasper County

Thomas Douglas & Co., having found that the name Golden Rule conflicts with that of another mine, have changed the name of their property, which now will be operated by the Aberdeen Mining Co. The mine is known as the old Lincoln, and is situated near Smithfield.

A new concentrating mill has been completed on the Clara Bell property, which is operated by L. F. Kinney.

MONTANA

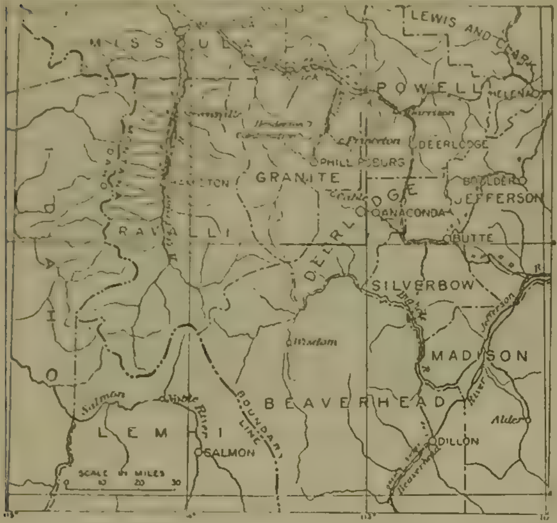
Fergus County

The Kendall M. Co., operating at Kendall, paid its eighty-second dividend of $10,000, at the rate of 2c. per share, on September 23. The total amount paid this year is $90,000. The company is incorporated for $500,000. Its dividends to date amount to $2,01[illegible],000. Messrs. Finch and Campbell, of Spokane, who are the largest shareholders in the Hecla, own the controlling interest of the Kendall.

LINCOLN COUNTY

Some samples of the ore from the recent copper discovery made on Parmenter creek were brought in recently by Frank Bryant, and it is stated that there is almost a mountain of the ore. The rock is freely sprinkled with peacock copper and comes from a 200-ft. dike, which carries veins varying from a foot to 20 ft. in width. A. Lacharity, E. W. Doe, and James Hurley are interested with Bryant in the property.

(Special Correspondence.)—E. H. Wilson, who has charge of operations at the Snowshoe mine for the Pacific Coast Smelting Refining Mining Co., has been appointed by Governor E. L. Norris as a delegate to the American Mining Congress, to be held in Chicago from October 24 to 28. **Mr.** Wilson was also appointed as a delegate from **California** by Governor Johnson. He attends the congress every year and is a member of the executive committee of the organization. Montana has two other delegates, from Helena and Butte.



MONTANA.

Libby, September 24.

MISSOULA COUNTY

An unnamed New York mining man is reported to have secured an option on the Texas claim, near Deborgia, from David Cromie, A. L. Thurston, and George Cox. The mine is east of the Rough Rider M. & M. Co. and north of the True Fissure. Mr. Thurston will have charge of the development work.

SILVERBOW COUNTY

(Special Correspondence.)—The High Ore mine will start up early in the coming month under the compressed-air system of hoisting ore. For more than a month workmen have been engaged in making the necessary changes to the engine. It has not yet been definitely determined which mine will be closed down next to allow the necessary changes to be made, but the changes on all the engines of the Anaconda company will go right along.

North Butte is producing copper laid down in New York at about 9c. per pound, and those who are in a position to know declare that it is earning much more than its dividend on its output of a little over 2,000,000 lb. per month. Not over a year ago the North Butte was probably not earning its dividend, but with the high-grade ore now being mined and hoisted to the surface, and the high silver value being obtained, there can be no question as to the company being in a position to earn its dividends. From all that can be learned, the mine is showing up remarkably rich at depth, and some of the richest ore ever brought out of a property in this district is assured in the near future. A 10-ft. vein was found while shaft-sinking was proceeding, and the ore is said to run 12% copper and 28 oz. in silver per ton. As soon as the stations are cut on the 2600 and 2800-ft. levels, these orebodies will be opened up.

Butte, September 25.

The North Butte M. Co. has declared a quarterly dividend of 30c. per share, payable October 21 to stockholders of record October 7. With this dividend the stockholders will have received since the first payment in September 1905, $9,538,000.

NEVADA

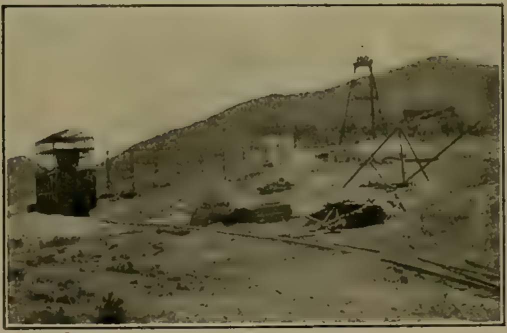
CHURCHILL COUNTY

The full 20 stamps of the new Nevada Hills M. Co., at Fairview, were dropping on September 19. The first ten started September 10. The water storage-tanks are practically filled, and plenty of water for milling purposes is assured, it is stated. The mill will gradually increase its present tonnage of 110 tons per day. The new shaft is down nearly 500 ft., and a station cut at the 450-ft. level. Driving is being done from the 570-ft. level of the old shaft. The new mill will eliminate the high freight and smelting charges incident to sending the ore to Hazen, as was done in the past. W. H. Webber has resigned as general manager for the Nevada Hills, according to report, and E. A. Julien, formerly of Goldfield, has been appointed to the position. Fred Siebert is consulting engineer.

HUMBOLDT COUNTY

Press despatches state that a vein of ore averaging more than $6000 per ton, chiefly in gold, with a little silver, has been found in the Friedman winze of the Seven Troughs Coalition M. Co.'s property.

An important discovery of manganese tungstate was made recently in the Adelaide portion of the Gold Run district by Robert Major. It is thought that other ore supposed to contain only zinc may also have tungsten.



BELMONT SHAFT.

(Special Correspondence.)—The Rye Patch Mining & Leasing Co., operating the Rye Patch mine, is awaiting the delivery of a stamp-mill. Air-drills also have been ordered. The company is shipping a car of ore per week to the Salt Lake City smelter, according to report. C. B. Conlin is general manager for the company, which has offices at Rye Patch.

The Star Peak mill has been bonded to Bela Kadish, of Baker, Ore., for $20,000. The property consists of six claims, on which about 1000 ft. of development work has been done. A 5-stamp mill and a tramway are on the property.

Rye Patch, September 23.

NYE COUNTY

The mill at Shoshone is to be taken to the Blue Jacket property, and applications for leases on property near the new site on Round mountain are said to be numerous. The contract for dismantling the mill has been let.

The Tonopah M. Co. of Nevada has declared a regular quarterly dividend of 25c. and an extra dividend of 15c. per share, payable October 21 to stockholders of record September 29. This will make a total of $1,600,000 paid in dividends this year, and a total of $8,050,000, or 805%, to date. The payment will leave in the treasury more than $1,000,000, and it is asserted that the present net earnings of the mine will permit the present rate of dividend and yet leave a surplus for the reserve fund.

Last week the Tonopah M. Co. shipped 3250 tons, the Belmont company 2350 tons, the Montana 849 tons, the Tonopah Extension 980 tons, and the Midway 50 tons of ore. The total, 7479 tons, is valued at $186,975.

A new vein has been found at the 1200-ft. level of the Belmont on a cross-cut driven north from the shaft. The vein runs east and west and dips northerly, according to press reports.

STOREY COUNTY

In the preliminary work for reclaiming the deeper levels in the north-end mines the winze formerly used jointly by the Mexican and Ophir has been found in apparently good condition to the floor of the 2900-ft. level. New pumps will be placed at the head of the winze, and water will be pumped to the 2450-ft. level of the C. & C. shaft, where a pump-station will be cut. From there it will be raised to the old Comstock adit. Pumps also will be placed at the 2650-ft. station of the C. & C. shaft.

WHITE PINE COUNTY

The Nevada Con. Copper Co. in August produced 5,249,514 lb. of copper, against 5,258,582 lb. in July. The company is reported to be well within its dividend-earning requirements.

OHIO

Ohio in 1910 produced 34,209,668 short tons of coal, with a spot value of $35,932,288. The increase in production is the largest ever made in one year. In 1909 Ohio produced 27,939,641 short tons, valued at $27,789,010. The increase was 22.44% in quantity and 29.3% in value. In 1910 more than half of the miners were on strike for a period equivalent to 25% of the average number of days worked.

OREGON

JACKSON COUNTY

Newspaper reports state that Adolph Meier, representing the Boston-Montana Silver & Copper Co., has been investigating the Rogue River district to select a site for a concentrator. The plant is to cost between $500,000 and $750,000, and would be built to handle the output of the Rogue River valley and southern Oregon mines. F. E. Steffey, of the Boston-Montana company, is expected in Medford in the near future.

SOUTH DAKOTA

LAWRENCE COUNTY

The Homestake M. Co. paid its regular monthly dividend of 50c. on September 25.

UTAH

SALT LAKE COUNTY

The west end of the 11,800-ft. tunnel of the Utah Metal M. Co. is in 5600 ft. and averaging 19 ft. per day. The east end, recently commenced, has been driven 100 ft. It is estimated that a year will be required to complete the remaining 6000 feet.

The Utah Copper Co. in August produced 9,010,669 lb. of copper against 7,555,407 lb. in July. The production for the quarter ended March 31 was 12,296,709 lb., and for that ended June 30, 24,469,812. The output for the third quarter will be unusually large, according to report.

SUMMIT COUNTY

At a meeting of the Uintah Treasure Hill Coalition M. Co., at which 853,000 of 1,000,000 shares were represented, it was unanimously decided to petition the court for dissolution of the corporation and distribution of assets. Each holder will receive about 10.7c. per share, as there is $106,000 on hand, received from the sale about nine months ago of the company's property to the Silver King Coalition M. Company.

WASHINGTON

FERRY COUNTY

The Ben Hur Leasing Co., with C. M. Kingston, general manager, and John Benson as superintendent, began sinking the Ben Hur shaft from the 300-ft. level September 18 and is sinking two compartments 5 ft. per day. Three sets of timber were put in during the week. The original plan of raising from the 400-ft. level while sinking from above was abandoned on account of there not being sufficient boiler power to run the compressor and two hoists.

The Hope company has sunk the new shaft on the cross-vein 63 ft. It has passed through several stringers and gives evidence of the vein being much wider below than was supposed from the width of the cropping. While the vein quartz is very hard and solid from the cropping to a depth of about 30 ft., below that depth it is much oxidized and brecciated, and the stringers are separated by andesite breccia. The ore near the bottom of the shaft has altered very little in sinking the last 30 ft. On the 300-ft. level the east drift on the hanging vein is in 75 ft. On the cross-vein the drift is in over 50 ft. on ore assaying from $15 to $50 per ton.

The San Poil Con. company resumed work September 5 with nine men. On the No. 1 level a stope has been started on a new shoot 4 ft. in width. The ore assays from $29 to $64 per ton. On the No. 2 level a raise has been started on the same shoot. There the ore assays from $16 to $27 per ton. In the North San Poil ground, at about 350 ft. north of the No. 1 raise, a new stope, 30 ft. long and 4 to 5 ft. wide, is up 20 ft., the ore assaying about $26 per ton. The company will ship to the B. C. Copper Co., at Greenwood, B. C. Since resuming work three carloads have been shipped, and three more cars are being loaded to go out September 26.

In the Lone Pine workings the Republic Mines Corporation is stoping ore northeast from the winze on the 400-ft. level. The stope is about 5 ft. in width. The ore, more uniform in value than above, assays about $20 per ton. In the east raise ore which assays from $20 to $30 per ton is being stoped.

At the Surprise mine, on the 300-ft. level, at a point about 70 ft. south of the turnsheet, a stope about 25 ft. long and 8 ft. wide is up 20 ft. in ore that assays about $70 per ton. From this stope a cross-cut has intersected the vein 25 ft. in ore averaging about $25 per ton. North of the turnsheet, on the same level, the drift is being slowly extended, on acount of the air being bad, with no present means of ventilation. It is now in the porphyry dike, which has apparently widened at this depth to 35 or 40 ft. From the 200-ft. level a raise is being driven toward the Wallek stope, at the bottom of which is a bunch of ore of good shipping grade, 25 to 30 ft. in length and 8 ft. wide. A line of 8-in. air-pipe is to be hung up in the south drift for ventilation. From the 600-ft. level, through the Quilp mine, a car of ore is being shipped per day, the assays from which have been running the past week from $17 to $130, with an estimated average of $65 to $70 per ton.

At the Knob Hill mine new work has been started on the 400-ft. level, in driving northward toward the extension of the Pearl-Surprise vein through the Mud Lake claim, which belongs to the Knob Hill company. The distance to be driven is about 600 ft. In the raise from the 400 to the 200-ft. level a stope has been started 100 ft. above the former, on ore 9 ft. in width which assays about $35 per ton. Southwest from the first mentioned, another raise has been started on a cross-vein, on which the company will begin stoping ore in about ten days. On the No. 2 level high-grade ore, averaging about $100 per ton, is being stoped about 3 ft. in width. The mine is looking well throughout, and the development work is kept well ahead of the production of six carloads of ore per week. At present 22 men are employed on two shifts.

Republic, September 23.

Okanogan County

C. H. Neil, ex-judge of the Superior Court of Ferry county, has bonded the Caaba mine, on Mt. Ellemeham, on the Similkameen river, near Nighthawk, and connected with the early history of the county. The consideration has not been made public.

Nighthawk, September 23.

CANADA

British Columbia

The net profit of the Granby Con. M. S. & P. Co. for the year ended June 30 was $216,525, according to figures submitted in connection with listing $150,000 treasury stock on the New York Stock Exchange. The net profit for the previous year was $564,947. The company for the year recently ended produced 17,855,130 lb. of copper at an average cost of 11.09c. per pound, and sold it at an average price of 12.311c. The cost of production for the previous year was 10.3c. per pound. The silver yield was 343,504 oz., and the gold 41,744 oz. The silver sold at an average price of 53.564c., and the gold at $20 per ounce. The company has a total surplus of $2,532,414. The $150,000 issue of stock, states G. M. Luther, president of the company, is to enable the company to make final payment on the entire issue of stock of the Hidden Creek Copper Co., on which an option was first obtained last October. The Hidden Creek property is on Goose bay, Cassier district, British Columbia, and consists of 412 acres crown-granted mineral rights, the Maple Leaf and Bunker mineral claims, not yet granted, 600 acres of land, and a recorded water right. About $300,000 had been spent on development at the time of sale. Cores in the lowest workings assay about 3% copper. Work has been started on a 400-ft. wharf, a 6000-ton ore-bunker at the dock, and a 4000-ton bunker at the mine. An electric plant is being constructed and other improvements are under way.

GRANBY SMELTER.

Spokane directors of the Rambler-Cariboo M. Co. have received advices from the manager of the property near McGuigan that the face of the 1200-ft. level continues in about 5 ft. of solid galena. This showing now has lasted for more than 30 ft. Since the 1200-ft. level entered the second lens of ore it has been advanced 180 ft., and for the entire distance the pay-streak has averaged more than 3 ft. in width of ore that assays 250 oz. of silver and more than 60% in lead per ton. The first shoot discovered on the 1200-ft. level was 60 ft. long and of an average width of 3 ft. of clean galena.

S. N. Ross, of Salmo, while in Spokane, reported that the Canadian Consolidated M. & S. Co. is planning to develop the H. B. property at depth by means of adits and diamond-drilling. The property has been bonded for $500,000. The Queen mine is operating a 20-stamp mill which has been in continuous service for nine years.

Ontario

A test-pit on the No. 16 vein of the Lucky Cross property has opened up one of the richest ore-shoots so far found in the Swastika district. This vein has been uncovered for about 350 ft., and for a distance of over 100 ft. free gold can be seen throughout the quartz, according to late reports. A test pit sunk to the depth of 8 ft. some weeks ago showed 2 ft. of quartz which gave an average assay from wall to wall of $112 per ton. The new showing in the second test pit is decidedly richer than anything heretofore found on the property.

La Rose Con. and Nipissing mines both declared their fourth quarterly dividends for the year on September 18, the dividends to be payable October 20. The La Rose dividend, of 2%, will involve a disbursement of $150,000, and brings the total of dividends paid since October 1905, when the first was paid, to 35 per cent.

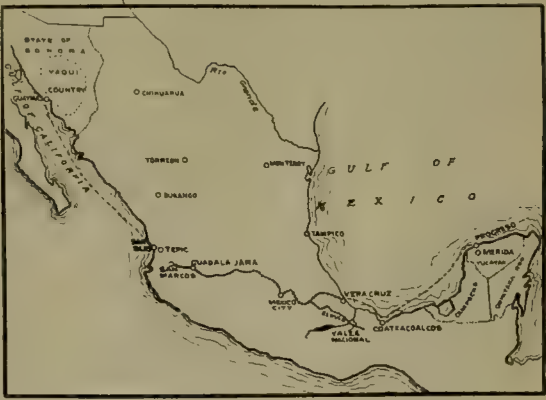
The Nipissing regular 5% dividend and customary bonus of 2½% will result in a disbursement of $450,000. The company in all, with the present declared dividend, will have paid stockholders 121½% on their investment.

The report of the Beaver Con. Mines, Ltd., for the quarter ended August 31, shows that the company has done 1102 ft. of development work, an increase of more than 400 ft. over the work of the preceding quarter. Two cars of high-grade and eight cars of low-grade ore, aggregating 648,194 lb., and valued at $133,000, were shipped. Payments are due from the smelters on about $135,000 worth of ore, part of which was shipped during the previous quarter. The figures, it is asserted, indicate an increase during the quarter of $68,718 in liquid assets. The company has a cash balance on hand of $59,960.

MEXICO

Chihuahua

Newspaper reports state that plans are being made for the construction of an aerial tramway from the San Cristobal mine, in the Parral district, to the Veta Colorada mill. B. V. Gordon is manager of the San Cristobal mine.



MEXICO.

Additions to the mill of the Tajo property in the Parral district are planned. H. H. Utely is manager.

Durango

The Restaurador mine in Guanacevi, formerly owned by Ayton & Co., has been sold to an English syndicate. The property has a large mill. Development was stopped a year ago pending the completion of the deal.

Hidalgo

The San Rafael y Anexas company is planning to erect a cyanide plant on the Los Remedios properties, Pachuca district.

Sonora

Exceptionally rich ore has been found recently in several properties of the Rey de Oro district, about 50 miles east of Magdalena, and about 15 miles south of the Santa Rosalia mine. On the Patsie denouncement, owned by O. B. Glover, ore assaying $1000 per ton, according to press reports, has been discovered at a depth of 150 feet.

The reduction plant of the Cerro Gordo mine, Cumpas, has had a test run, but some small changes will be made before regular production will be commenced.

Personal

Professional men are invited to send news of their engagements and travels. Such news is interesting to friends.

F. L. SIZER was in Nevada last week.

ERROL MACBOYLE has returned from Alaska.

JOHN FINLAY, of Los Angeles, is in San Francisco.

GELASIO CAETANI is expected from Colorado Monday.

W. M. KNOX is drilling placer ground near Vladivostok.

JOHN B. FARISH is at the St. Francis hotel, San Francisco.

FREDERICK BRADSHAW has been in San Francisco for a few days.

GEORGE H. GARREY has returned to San Francisco from the South.

W. H. STORMS is examining mines in Nevada county, California.

W. C. RALSTON has returned from a visit to Tonopah and Virginia City.

S. H. BALL has returned to New York from a six weeks trip through Mexico.

W. P. O'MEARA, of Salt Lake City, is at the St. Francis hotel, San Francisco.

SUMNER S. SMITH has gone from the Matanuska coal-fields to Ketchikan, Alaska.

F. W. BRADLEY has been at Kellogg, Idaho, and is expected at San Francisco Monday.

T. LANE CARTER has gone from Mexico to inspect some mining properties in northern Arizona.

C. W. PURINGTON and NORMAN C. STINES have been at Harbarovsk on their way to Nicolaievsk.

R. P. WHEELOCK has been appointed superintendent for the Enterprise M. R. & I. Co., Kingman, Arizona.

J. A. HOLMES has returned from Alaska. He was at Kellogg, Idaho, this week and has gone to Chicago.

E. C. ENGELHARDT has accepted a position with the American Smelting & Refining Co., at Garfield, Utah.

E. S. RUST has been appointed manager of the Seattle branch of the Yuba Construction Co., with offices at 1224 Alaska building.

W. H. GRAHAM has returned to San Francisco from Libby, Montana, where he has been for a month. He expects to return there in about two weeks.

JOHN D. RYAN, WILLIAM E. COREY, R. L. AGASSIZ, W. D. THORNTON, P. L. FOSTER, and L. D. RICKETTS, visited Miami, Inspiration, and Live Oak last week.

C. B. CONLIN, formerly superintendent of the Commodore gravel mine in Sierra county, California, is in charge of the Rye Patch M. & L. Co., at Rye Patch, Nevada.

P. R. PARKER, formerly manager of the Seattle branch of the Yuba Construction Co., has been appointed superintendent of the company's plant at Marysville, California.

RENE E. HAZARD will leave New York early in October for Medellin, Colombia. He is taking with him a large amount of machinery for the Sambenigo Mines & Estates Co., for which he is manager.

The local committee in charge of arrangements for the San Francisco meeting of the A. I. M. E. will meet at the Commercial Club today at noon.

Obituary

R. F. MORTON, who died at his home in Berkeley, California, September 27, was a civil engineer who had lived many years in California and been concerned in the making of many local maps. Mr. Morton was a particularly excellent draughtsman, and numerous examples of his work have appeared in the *Mining and Scientific Press*. His large map of the oilfields of California, involving months of careful compilation, is especially well known.

Company Reports

THE BROKEN HILL PROPRIETARY CO. LTD.

The report of this company, operating mines at Broken Hill, Victoria, and works at Broken Hill and Port Pirie, South Australia, for the half year ended May 31, 1911, shows that during the period 52,441 tons of ore was treated at the old mill, producing 10,638 tons of lead concentrate (57.43% lead, 27.08 oz. silver) and 7980 tons of slime (13.20% lead; 16.47 oz. silver). The new mill treated 159,609 tons of old tailing, producing 5090 tons of concentrate (51.56% lead, 26.65 oz. silver) and 10,737 tons of slime (11.65% lead; 16.67 oz. silver). The residue from both mills (178,125 tons) was sent to the zinc concentration plant, which produced 44,110 tons of zinc concentrate (44.88% zinc; 6.95% lead; 12.86 oz. silver). The smelter treated 85,832 tons of material, yielding 43,563 tons of bullion. The refinery produced 2,018,887 oz. silver; 1410 oz. gold, 38,749 tons of soft lead, and 293 tons of antimonial lead; 665 tons of spelter and 100 tons of blue powder was produced. A fifth furnace will be blown in soon, and the Dwight-Lloyd smelting plant is now in course of erection. The receipts from the sales of metals, plus increase of metals on hand since last report, amount to £728,841. Operating costs for the period were £561,027, leaving a gross profit for the six months of £167,814. Dividend No. 155, of £48,000, was paid. The subscribed capital of 960,000 shares at 8s. amounts to £384,000. Of the £260,000 reserve and insurance fund £239,837 has been used in the company's business, and the accumulated profits, £669,054, are being used in the conduct of business. A contract has been made with the British Broken Hill Proprietary Co. to treat its lead concentrate, about 2000 tons per month, at the Port Pirie smelter. The zinc concentrating plant has given most satisfactory results.

ANACONDA COPPER MINING COMPANY

This company has an authorized capitalization of 6,000,000 shares of a par value of $25 each, 4,220,000 shares having been issued. During 1910 the capital stock of the company was increased from 1,200,000 shares to 6,000,000, in order to purchase the properties of the Boston & Montana Consolidated Copper & Silver Mining Co., the Red Metal Mining Co., the Washoe Copper Co., the Butte & Boston Consolidated Mining Co., Big Blackfoot Lumber Co., Parrot Silver & Copper Co., Alice Gold & Silver Mining Co., and the stock of the Diamond Coal & Coke Co. The purchase was effected by the exchange of $3,020,000 shares of the Anaconda company, and April 1, 1910, the operations of the different companies was unified, and the mines are now operated as departments of the Anaconda Copper M. Co. In June the properties of the Original Consolidated Mining Co., the Clark Montana Realty Co., and the Colusa-Parrot Mining & Smelting Co., belonging to the Amalgamated Copper Co., were purchased for 112,500 shares of Anaconda stock. The properties are now operated by the Anaconda company, with the exception of certain claims in which the ores are chiefly zinc, which were not included in the transfer. The Colusa-Parrot smelter has been closed and the concentrator leased to W. A. Clark. The mining operations of the company are now carried on under (1) the Anaconda department; (2) the Boston & Montana department; (3) the Butte & Boston department; (4) the Parrot department. During the year there was received from the sale of copper, gold, and silver $30,943,508; the amount of these metals on hand at the end of the year is valued at $14,736,503; other sources of income bring the total to $46,391,126. Mining expenses, including development, amounted to $12,628,535; reduction expenses at Anaconda and Great Falls, $7,203,880; transportation, refining, and selling expenses, $3,001,377. The profit for the year was $5,720,903, and during the year dividends 38, 39, 40, and 41, amounting to $6,930,000, were paid. The assets of the company are given as $118,720,218, of which $93,078,071, is represented by lands and equipment, $3,444,343 by deferred accounts, and $22,197,804 by current assets, chiefly metals on hand. The report contains summaries of the work of the different departments of the company. During the second half of the year the economies resulting from consolidation began to be shown.

ALASKA MEXICAN GOLD MINING COMPANY

The Alaska Mexican mine is on Douglas Island, Alaska, between the 700 Foot Claim and the Ready Bullion mine of the Alaska United. It is one of the Treadwell family of companies, for which F. W. Bradley is consulting engineer, Robert A. Kinzie superintendent, and E. P. Kennedy assistant superintendent. The report for the year 1910 shows both the mine and the company to be in excellent condition. Since 1893 this mine has produced 3,132,954 tons of ore with an average yield of $2.74 per ton and a total of $8,592,487. Of the latter, $4,879,178 was from the sale of bullion and $3,713,309 was won in the form of concentrate. The operating profit for the period was $3,087,891, equivalent to $0.98 per ton, the operating costs have been $1.76, and the dividends paid have amounted to $2,742,381. In considering these figures it is well to remember that this company follows the policy of paying for plant and improvements out of income, so that the operating cost includes these items. For the year 1910 the figures were: tons crushed, 218,960; yield per ton, $3.50; operating profit per ton, $1.74; dividends paid, $342,000. It is interesting to note that the operating cost for the year, $1.76, was exactly the same as the average since the mine opened, and that the dividends paid amounted to almost 44% of the gross income. The ore reserve at the end of the year amounted to 1,093,029 tons of an average assay value of $3.41. This for a low-grade mine is an enviable record. An interesting detail in the report is a table showing quicksilver losses. These amounted to 295 oz. lost in retorts and 16,483 lost in the mill. The whole loss was 28.49%. This, while larger than usually considered to occur, is probably not greater than the actual loss in many mines. The chrome steel used for shoes crushed 2.78 tons per pound of steel.

AMERICAN SMELTERS SECURITIES CO.

The sixth annual report of this company, for the year ended May 31, 1911, shows that the earnings from operation of the smelting and refining plants for the year were $6,110,477, and from mines $1,850,800. Income from investments amounted to $77,174 and miscellaneous earnings $234,544. On ordinary repairs and replacements $944,409 was spent; $42,261 for corporation and excise taxes; $365,400 for administrative expense; interest, $662,176; discount on bonds, $16,667; depreciation, $650,000. The balance available for dividends was $5,092,083; from this preferred A of $1,020,000, and preferred B of $1,500,000 was paid, leaving a balance to be carried to profit and loss account of $2,072,083. Miscellaneous profit and loss adjustments amounted to $381,962 and depreciation in the value of investment stocks to $2,754,895, leaving a balance at the end of the year of $1,623,423, or a decrease of $64,774, compared with last year. The capital stock of the company consists of issue A of preferred, amounting to $17,000,000, and B preferred, $30,000,000, the common stock amounting to $30,000,000, and $15,000,000 of 6% debenture bonds have been issued. Current liabilities amount to $2,348,115, reserve funds $90,893, and profit and loss account $1,623,423. The property is valued at $76,261,106; investments, $2,399,800; working assets, $1,191,198; current assets, $7,465,007; account collectible, $3,432,248; loans and cash on hand, $4,605,729. The expenditure of $594,724 for new construction and permanent improvements during the year was placed to property account, and $650,000 charged off for depreciation. During the year $15,000,000 in 6% gold debenture bonds was issued, payable February 1, 1926, and sold to the American Smelting & Refining Co. on the terms given in the report of that company. These bonds were issued for the purpose of funding the indebtedness of the American Smelters Securities Co., paying the deferred liability on account of the purchase of the capital stock of the Baltimore Copper Smelting & Rolling Co., and for other corporate purposes.

Decisions Relating to Mining

Specially reported for the MINING AND SCIENTIFIC PRESS.

Location of Mining Claim — Marking Boundaries and Discovery

The location of a mining claim is invalid where the boundaries of such claim are not marked on the surface. Evidence of seams of minerals on a claim located without any showing as to what the minerals are is insufficient to establish a discovery of valuable minerals within the lines marking the claim that constitutes an essential element to a valid location of a mining claim.

Harper *v.* Hill, (California) 113 Pacific, 162, January, 1911.

Injury to Miner—Ignorance of Rules

In an action by a miner for injuries caused by a car jumping the track, the court instructed the jury that although the mine-owner had a rule requiring the miners to stand back when a trip of cars are passing on the main line, yet if the injured person did not know the rule, he would not be bound thereby, and would not be precluded from recovery by negligence on the part of the mine-owner.

Consumers' Lignite Co. *v.* Cameron, (Texas) 134 Southwestern, 283. February, 1911.

Death of Miner—Controverted Question of Negligence

In an action for the death of a miner by the fall of a portion of the roof, the controversy arose as to whether props supporting the roof were removed by the order of the mine foreman or by the miner without authority from the foreman. The question as to whether the props were taken out in accordance with the express direction of the mine foreman was for the jury, and the court properly instructed the jury that unless they found by fair preponderance of the evidence that the foreman was negligent, the plaintiff could not recover, and if they found for the plaintiff it must be because the foreman was negligent either in failing to give proper instructions as to how the work should be done, or in giving faulty instructions.

United States Gypsum Co. *v.* Sliwienska, 183 Federal, 688. December, 1910.

Duty of Mine-Owner to Furnish Safe Place for Work in a Mine

The statute of Washington requires a coal-mine owner to keep sufficient timber at any mine where it may be required for props, in order that the workmen may properly secure the workings and prevent them from caving in. It requires the owner to send into the mine all necessary props when required and to deliver them at the entrance of the working place. The statute also provides for inspection, underground maps, ventilation, measurement of air, openings and exits, signals, hoisting pumps, safety lamps, proper tools, and care of the men engaged. In an action for injury to an employee based on this statute, it was decided by the Supreme Court of Washington that the statute did not apply where it was shown that at the time of injury the injured employee and others were engaged in driving a rock tunnel to explore the territory and discover a ledge, and where no coal had been discovered or worked up to the time of the accident: that such tunnel was not a coal mine, but it might become a part of one, depending upon future developments, and it would be extending the statute beyond the limit of legislative intention to hold that a rock tunnel was a coal mine and subject to the operations of the statute. But this construction of the statute does not relieve the employer of his common-law duty to use that care which the cirsumstances and character of the work require for the protection of workmen in constructing the tunnel.

Hemmingson *v.* Carbon Hill Coal Co., (Washington) 112 Pacific, 1111. February, 1911.

Book Reviews

Any of the books noticed in these columns are for sale by, or can be procured from, the MINING AND SCIENTIFIC PRESS.

PRACTICAL GEOLOGY AND MINERALOGY. By W. D. Hamman. The Mining Man's Library, Vol. I. Pp. 224. Ill., no index. Pub. by Way's Pocket Smelter Co., South Pasadena, California, 1911. Price $2. For sale by the *Mining and Scientific Press.*

There is a recognized need for more scientific books written in simple language and designed to meet the everyday wants of the common man. Unusual difficulties, however, must be faced the moment the attempt is made to meet this want. The lack of preparation on the part of the reader makes the task of the author almost impossible of accomplishment. A statement that, made with the unconscious mental qualifications that exist in the minds of a scientific man, is eminently sound, is entirely misleading to a man whose preliminary training has not prepared him to make similar qualifications. On the other hand, it is the common experience of teachers that if a fact is stated to beginners in any but positive form, it makes no impression.

It is at once apparent that in scope he has covered fairly well the field chosen. The salient facts of geology, mineralogy, petrology, and mineral deposits are treated. The statements are plain and easily understood. Evident care has been used to secure exactness. In general the author is as judicial in his discussion of controverted problems as this purpose will permit. A reader feels instinctively that any mistakes of facts or of emphasis are honest mistakes, that the author has no pet theory to bolster. None the less there are numerous mistakes of fact, and, in my opinion, some of emphasis. There are places where the discussion is somewhat out of focus and the author has not always been in touch with the latest and best information—as, for example, in discussing the cause of the Glacial Period. As mistakes in statement of fact may be cited that on p. 35, that quartzite first made its appearance in the Cambrian; that on p. 54 that marble has its origin in fusion of limestone; on p. 63 that gneiss differs only from granite in being stratified; and others. Even these cases are mainly erroneous in being bald statements without qualification. Quartzites were long thought to appear first in the Cambrian, possibly fused limestone would result in formation of marble, though certainly most marble has not so originated, and 'stratified' is not the word a geologist would choose to describe gneissic structure, because of the genetic significance that the word connotes. There is an unconscious humor in referring to a certain famous doctrine as the "nebulous" hypothesis, and the figure on page 40 has been carelessly labeled. It is, of course, a map of North America in the Tertiary period and not a map of the period, the latter being a time term. The statement that placer nuggets have been traced to fusion will be questioned, and the belief that the definition of feldspar on p. 68 "will enable anyone to distinguish" that common mineral, seems hopelessly optimistic. The illustrations are faulty. Oyster shells are hardly the most appropriate illustration that could be chosen for the Silurian; the calcareous crystals on p. 52 look suspiciously like quartz, and the oven for making plaster, shown in Fig. 16, may have been used at some previous time, but certainly does not illustrate modern practice. On the whole the author has done much better than is common in writing such books. The work will prove helpful, and no doubt errors will be eliminated in future editions. We could wish that some effort had been made, by suggestions and frequent reference, to lead its readers into wider fields of reading. They would probably not read many of the books cited, but it might correct their tendency to go away with the satisfied feeling of having mastered the whole subject; a feeling that Mr. Hamman has no apparent intention of giving them, but which they none the less probably get. Other books of the same series are promised by the publishers, and they will be wished success in their experiment by all interested in spreading information among miners and prospectors.

EDITORIAL

CALIFORNIA welcomes the American Institute of Mining Engineers to the city by the Golden Gate.

OUR Salt Lake City contemporary, *Mines and Methods*, has trained its guns upon us, but as this was to be expected, we remain undisturbed.

NOME has been suffering from early storms this fall, but no considerable damage has been done, beyond the loss of a few lighters and the coal wharf at Fort Davis.

TRUSTS are meeting 'heavy going' these days, the most recent acquisition to the list of delinquents being the 'Lumber Trust', against which suit has been filed at Denver.

AUGUST production of oil in California amounted to 7,208,984 bbl., or a daily average of 232,546 bbl., the gain in average daily production of 8744 bbl. over July being largely due to the increased production of the Midway field.

AN INTERNATIONAL organization as the solution of the problem of forming a merger of copper producers at a time when monopolies are being ordered to dissolve, is suggested by our New York correspondent. But the immunity thus secured would probably be short-lived; an international commerce commission at The Hague is equally feasible.

NAVIGATION on the coast of Alaska is beset with difficulties; narrow passages, strong and erratic currents, fogs, and too few aids to navigation in the form of lighthouses, channel marks, and accurate charts. Added emphasis is given by the beaching of the *Edith* on Level island in Sumner strait not far from Wrangel, the latest of a series of such disasters. Someone is at fault; a series of wrecks should not be necessary to bring the responsibility home.

PLATINUM continues to increase in price, having sold at $47.50 per ounce in New York on Tuesday. Dispatches from Russia say there is much excitement on the Ekaterinburg market, the 83% quality continuing to advance in price while iridium is in strong demand with none to offer. Chemists to whom platinum is a necessity are correspondingly depressed. Painstaking search fails to disclose new deposits of the platinum group of metals, and apparently the necessity of devising substitutes must soon be faced.

AMERICAN trade has become of much importance in the Near East, as is evidenced by the appearance of the *Levant Trade Review*, a quarterly published by the American Chamber of Commerce for Turkey, recently organized to promote Ottoman-American trade and industries. The first number contains much of interest, and we extend to both the organization and its journal our hearty wishes for their success. The growth and importance of trade with the Far East leads to the hope that a similar organization may be formed to promote trade relations between Asia and the Pacific Coast region. The recent visit of the members of the Associated Chambers of Commerce of the principal Pacific Coast cities to China, which is to be followed next year by a visit of Chinese merchants to the United States, was an excellent step in the right direction; more should follow.

RAILROADS are accustomed to picture themselves as ground between the upper millstone of rate regulation by the Interstate Commerce Commission, and the lower of increased operating costs, chiefly due to the demands of labor, but when annual reports appear the harrowing panorama is temporarily obscured. The Atchison, Topeka & Santa Fé system, one of the loudest in its wails, after making, and properly so, heavy expenditures for maintenance and improvement, still exhibits an increase of over a million dollars in the excess of profits over fixed charges. The Illinois Central records the year ended June 30 as the most prosperous in its history, showing an increase of 5.34 per cent in gross earnings over the preceding year, yielding an operating profit of 10.20 per cent, or 3.20 per cent in excess of its dividend requirements. On this showing, most of the shippers will also wish to be oppressed, if similar results will follow.

COPPER production has undergone sweeping changes of recent years, and the readjustment to changed conditions has given rise to many tremors and has been attended with not a little friction and heat. But, like geotectonic adjustment, such changes seem resistless, even though their advent may be undesirable to many; neither blinking the facts, nor distortion of them serves as effective preventive. On the following pages the chief features of the technology of the methods employed in the mining and milling of large low-grade copper deposits are briefly reviewed, and Mr. C. B. Lakenan, general manager for the Nevada Consolidated, contributes to our discussion column further data of much interest. These new methods merit extensive critical discussion, but of a character different from that which they have heretofore evoked. We hope that many engineers will join in the serious discussion of the problems involved, and from such a discussion results of value will be obtained.

WINTER is closing in on the Far North. The last steamer has backed away from the wharf at Dawson and started down the Yukon. From now only the White Pass route will be open and the last boat up the river is scheduled to leave October 10. At Nome 'last' boats are loading, and at Fairbanks and Chitina stages are being prepared for the winter run. The fall exodus is in full swing, and everyone whose business permits is starting 'outside.' Thousands, however, will stay behind, and he knows but little of Alaska and the Yukon who thinks of winter as a period of hibernation. Ice and snow make the trails good, and thousands of pounds of freight are now waiting for the freeze-up which permits transportation to the scattered mines and prospects that are to become mines. Fewer people will be in the country, but underground work will be pushed vigorously, and great piles of frozen dirt will grow apace awaiting the breath of spring to unlock the gold.

REJECTION of closer relations with the United States by Canada, accompanied by intimations that our commercial, legal, financial, social, and ethical standards are by no means what they should be, as voiced by Rudyard Kipling, might well cause chagrin, but some balm for the wound may be found in a recent pamphlet by Mr. J. W. Moncada, ex-Minister of the Interior for Nicaragua, who sees in the United States the guide, friend, and protector of the Latin-American republics. Governments, which in the twentieth century are by the people, are therefore delightfully human, one phase of which is inconsistency. Canada, which long sought for reciprocity, has rejected it when offered; the Latin-American republics, which sometimes employed the Monroe Doctrine as a shield for schoolboy naughtiness, but apparently regarded it as a menace to entire independence, on the whole, may well come to recognize in the United States a help to true progress. The United States is not likely to wish to acquire more territory—anyone who will promise to give the Philippine Islands a good home and be kind to them should apply to Washington, D. C.—and closer trade relations with the adjacent portions of North and South America can result only in mutual advantage.

EUROPEAN countries have exhibited much friction in their international relations recently, and public attention has been so engrossed with the Moroccan situation that the declaration of war upon Turkey by Italy came as a surprise. Tripoli is but a couple of hours by steamer from Sicily, and in the course of time a large Italian population have engaged in trade and industrial development along the adjacent African coast. Under Turkish rule a situation has arisen in Tripoli which has some resemblance to that in Cuba in 1898. The war is likely to be even more brief than the Spanish-American war, Germany having already proposed what is practically a sale of Tripoli to Italy, and the really important effects of the outbreak are likely to be upon the Government of Turkey, which has scarcely a firm seat in the saddle as yet, and upon European relations generally, more especially in regard to Morocco. Meanwhile an element of humor is injected into the situation by the comments of the daily journals, some of which seem to think Tripoli a city in Morocco, while a well known daily gravely suggests that, like Great Britain in South Africa and Russia in Manchuria, Italy is likely to find a war conducted at a great distance from a base of supplies long and arduous!

Welcome to the Institute

The American Institute of Mining Engineers, which is in session at Los Angeles today, and which will hold meetings at San Francisco next week, is the largest and most representative organization of mining engineers in the world. With a distinguished history extending back to 1871, and a membership of over 4000, representing nearly all the countries on the globe, the Institute includes practically all the great engineers who have contributed to the progress of American mining and the spread of American practice abroad. It is a catholic body and extends membership not only to practising engineers, geologists, and metallurgists, but the students who are to become the engineers of the next generation, and to lawyers, business men, and others whose affiliations are with mining. The wisdom of this generous welcome to associates has been at times a matter of discussion and criticism. For ourselves, we have held that the Associate membership is a source of strength to the Institute rather than of weakness. If the line has been drawn a bit carelessly at times, the amendments to the constitution now under discussion and presented in full on another page, will right the matter. While there are many members who possibly have done little to further the interest of either the Institute or of mining, it is extremly rare to find an American mining engineer of real ability and achievement, who is not a member of the Institute. In California alone there are more than 300 members. Around San Francisco Bay there are 120. What is true of California and San Francisco is equally true of every other great mining State and centre in America. Everywhere the Institute is at home, because everywhere there are enough local members to assure a good meeting. Reinforcing the California members this week a large delegation has come from the East, with smaller ones from North and South.

It is the pleasant duty of the local members to meet and entertain the visitors. A dozen years have passed since they last had that privilege, and, while the California of 1911 is a very different California from that of 1899, the same hearty welcome awaits the visitors.

In 1898, the year preceding the last meeting of the Institute in California, the total mineral production of the State amounted to $27,289,079. Of this amount more than half, $15,906,478, came from the gold mines, and, indeed, mining in California was then dominantly gold mining. The four mineral products following next in order of value were petroleum, $2,396,420; copper, $2,475,168; quicksilver, $1,188,626; borax, $1,153,000. In 1909, the last year for which complete figures are available, California mines produced $79,945,078. The difference in the distribution of the production is as significant as is the growth of the total. Gold, though amounting to $20,703,600, is no longer first. It had even in 1909 been surpassed by petroleum with a total value of $30,675,267. Third in the list was copper, with an output valued at $6,963,932. Quicksilver had dropped to $658,688, a reflection not only of decreasing grade of ore, but of increasing consumption of cyanide. Borax amounted to $1,534,365, a moderate increase on the production of 1898. A whole group, however, of materials only produced in insignificant amounts in 1898 have come to the front in the interim. A great cement industry has been established, and an output worth $5,899,784 tells the same tale of industrial expansion as does a production of clay goods to the amount of $4,437,165, and of stone to a total of $3,444,900. Later figures where available but emphasize the contrast. California is no longer the State of the Argonauts, but an industrial commonwealth in which fuel and structural materials are of first importance.

Gold mining, the historic indvstry of California, is still its leading metal-mining industry, and there could be no more mistaken notion than that the day of mining has passed in this State. Gold mining has increased mightily, but other industries have grown faster. California is still the first American State in point of gold production, and in 1910, according to the figures of the Mint, yielded $21,146,150. The sources of the production in 1898 and 1910 stand in interesting contrast. Then the five leading counties in gold and silver production were: Nevada, $2,037,104; Amador, $1,808,105; Tuolumne, $1,750,535; Shasta, $1,031,948; Kern, $1,023,933. In 1910 they were for gold alone: Yuba, $3,204,273; Amador, $2,646,246; Nevada, $2,533,843; Butte, $2,487,791; Shasta, $1,533,728. The changes in the industry are even better shown by figures compiled by Mr. Charles G. Yale for the interesting souvenir volume published by the California Miners' Association in 1899, and for his official report to the United States Geological Survey for 1910. In 1898, $12,488,321 worth of gold came from quartz mines, $1,028,547 from drift mines, $962,192 from hydraulic mines, and $1,841,473 from placer mines. In 1910 the figures were: quartz mines, $10,005,190; drift mines, $516,929; hydraulic mines, $635,498; sluicing, $186,114; dredges, $7,550,254. The most important and significant change has been the growth of dredging from a position where it was not separately listed, the yield in 1898 being $18,847, to a position but little below that of the quartz mines. In the souvenir volume already mentioned, Mr. R. H. Postlethwaite gave a graphic picture of the dredging industry that was then just beginning. Three small dredges were then in operation at Oroville with buckets of 3¼ cubic foot capacity. Now there are 68, ranging in size up to giants with buckets of 15 cubic foot capacity. Next week the engineers will be taken to Folsom where, as guests of the Natomas Consolidated of California, they will see some of the largest and most modern boats. On another page of this issue Mr. Newton Cleaveland, who is in charge of the work for the Natomas company, gives interesting details regarding one of the boats that will be visited. The great mines of the Mother Lode and in Nevada county have held their own, but by their side has grown up another mining industry of first rank.

In 1898 the petroleum production of California was 2,429,088 barrels. In 1910 it was 73,000,000 barrels, and the value direct and indirect is beyond calculation. When the engineers visited the State last, the Los Angeles, Summerfield, Kern River, and Coalinga fields had all been opened, but the great production had not begun. It is worth noting that these old fields are still producing oil, though the engineers will see a practically new industry both on the Coast and in the Valley. Cheap fuel, the long lacking requisite of industry on the Coast, is now available.

The same contrast may be observed between copper mining in 1899 and 1911. Then the Mountain Copper Company, Limited, was practically the only producer in the State. It made 21,422,000 pounds of copper in 1898, working on ore containing 8.42 per cent and wasting all the sulphur. Now this company has as an active companion in Shasta county the Mammoth Copper Company, and, temporarily idle, the Balaklala Consolidated Copper Company and the Bully Hill Copper Mining & Smelting Company. In the foothills of the Sierras the Penn Mining Company is producing. Ores assaying less than 2½ per cent copper were smelted in California this year and the Mountain Copper Company no longer wastes its sulphur. A plant on San Francisco Bay converts it into acid, which in turn is used for making fertilizer, and a great phosphate industry is being established in the West. The day of careless waste and open-handed generosity has gone from the sunny land first conquered by the Padres. Industrialism is now triumphant and every man must give accurate account of the materials that are placed in his hands. Men, however, have changed less than their environment. The sturdy spirit of enterprise that marked the pioneers of California rules their descendants. The changes noted have but broadened the field for success. Our visitors will find a State that faces the ocean of opportunity and a people with the spirit to achieve.

Rights of the Reader

In the September issue of *The Mining Magazine* Mr. T. J. Hoover refers to the inadvisability of publishing articles of any permanent value in journals of limited circulation. While we cannot agree with him in his designation of the *Western Chemist and Metallurgist* as a 'backwoods' magazine, yet the main point is well taken. Every engineer is now familiar with the phase rule, first published by Willard Gibbs in the proceedings of a small Connecticut society, whence it was only disinterred after the lapse of many years, by a German investigator and brought to its rightful recognition as one of the most notable achievements by American men of science. Graduate students at our universities not infrequently undergo the unpleasant experience of devoting several years to an investigation, only to find, when the work is well advanced, that all the essential features have already been published in some little known periodical. The loss in such a case to a young man of limited means is often serious, and a just regard for the rights of others, as well as a proper appreciation of the attention which a notable article should attract should prompt its publication in a medium which is easily available. A reasonable number of journals devoted to each phase of current thought are necessary in order that progress may be viewed from enough angles to obtain the proper perspective, but reckless multiplication should be decried as a hindrance rather than an aid to progress.

Recent Problems in Copper Production

AN EDITORIAL REVIEW

It is not too much to say that development during the last decade has completely revolutionized the copper situation. How sweeping the changes have been may be seen from a comparison of the tables below.

FIFTEEN MOST IMPORTANT COPPER PRODUCERS, 1901

(As given in *Mineral Industry* for 1902)

		Pounds.
1.	Anaconda, Montana	101,850,000
2.	Calumet & Hecla, Michigan	82,520,000
3.	Butte & Boston, Boston & Montana, Montana	58,029,000
4.	Copper Queen, Arizona	39,781,000
5.	United Verde, Arizona	34,520,000
6.	Montana Ore Purchasing Co., Montana	29,899,000
7.	Quincy, Michigan	20,540,000
8.	Arizona Copper Co., Arizona	20,535,000
9.	Tamarack, Michigan	18,001,000
10.	Butte Reduction Works, Montana	17,970,000
11.	Detroit, Arizona	17,535,000
12.	Osceola, Michigan	13,723,000
13.	Parrot, Montana	10,168,000
14.	Old Dominion, Arizona	10,094,000
15.	Colorado S. & M. Co., Montana	7,465,000

FIFTEEN MOST IMPORTANT COPPER PRODUCERS, 1911

(Estimated)

		Pounds.
1.	Anaconda, Montana	250,000,000
2.	Phelps, Dodge & Co.	133,000,000
3.	Utah Copper	94,000,000
4.	Calumet & Hecla	74,500,000
5.	Nevada Consolidated	63,000,000
6.	Calumet & Arizona	50,000,000
7.	Greene-Cananea	47,000,000
8.	Copper Range	32,500,000
9.	North Butte	28,000,000
10.	Quincy	21,500,000
11.	Granby	21,500,000
12.	Ray Consolidated	20,000,000
13.	Miami	15,000,000
14.	Shannon	15,000,000
15.	Tennessee	13,000,000

Ten years ago the important factors in the situation were the comparatively rich sulphide ores of Montana and the Southwest, the native copper ores of Lake Superior, and pyritic ores in various places. Some years since the latter were objects of great interest and attention, and were expected to have great influence on copper production. Later experience has gone to show that this importance was perhaps overemphasized. Large masses of pyritic ores are not everywhere available and with those known to exist it is not at all easy to maintain the sulphur content at the high level necessary for carrying on pyritic smelting, and when this Ultima Thule is attained the smelter manager is likely to find himself in the toils of neighboring agriculturists, as the problem of avoiding damage suits when smelting with over 30% of sulphur on the charge is by no means a simple one. The advent of the so-called 'porphyry coppers' has been the most significant event of recent years, and the important place which they have already taken is evidenced by numbers 3, 5, 12, and 13 in the table given above. To describe them somewhat epigrammatically, material not previously classed as ore is mined upon a larger scale and at a lower cost than before, by novel methods, and the resulting ore is milled with a greater recovery than previously deemed possible, with the final result that deposits which until recently had no value are now a source of great profit. So much ill-considered and misdirected criticism has been leveled at these enterprises that it seems desirable to review briefly the problems met in their exploitation. The following has been prepared after a brief study of the operations of the two most notable enterprises of this kind, the Utah Copper Co. and the Nevada Consolidated Copper Co. To the officers of these companies we are indebted for the facilities afforded in the study of their operations. Further details of much interest, contributed by C. B. Lakenan, manager for the latter company, appear on p. 458.

In dealing with these recent problems of copper production, we have to do not with new species alone, but new genera. It is not remarkable, therefore, that some have found themselves unable to believe in the results actually attained. A rough but not inapt comparison is to say that these new methods of work bear to the older methods much the same relation that a street railway system bears to stages and omnibuses. In other words, it is the relation between a large volume of work carried on at a uniform rate with a low unit cost, and a smaller volume of work to which a larger degree of individual attention and effort is given at a higher unit cost. Where work is carried on at the rate of ten thousand or fifty thousand tons per day it permits the use of methods which eliminate the factor of individual attention which makes high unit costs. The 'porphyry coppers' are large masses of igneous rock which carry small amounts of copper ore, fairly uniformly disseminated throughout the mass. Size and uniformity of content are, then, the essential factors. The problems are to determine the size and uniformity of content of the deposit, to mine it as cheaply as possible with a daily production of many thousands of tons, to mill the product with a high percentage of saving and at a low cost, and then to smelt the concentrate as cheaply as possible. These will be discussed in more detail, taking them up in their logical order.

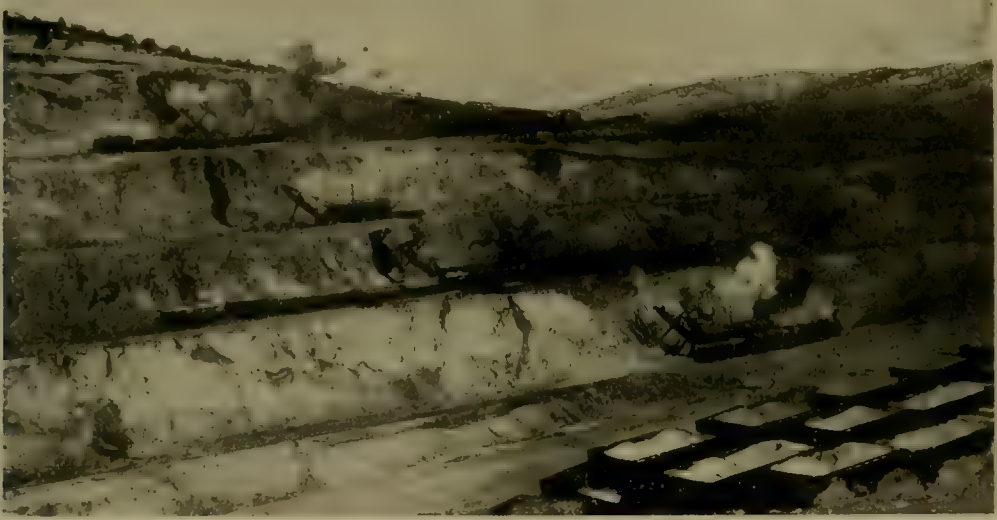
EXPLORATION

To determine the extent and content of ore deposits of this character the churn-drill affords the quickest, cheapest, and most satisfactory method, by far. The general features of churn-drilling have frequently been discussed in these columns and it would not be profitable to review them here. One or two points may be mentioned, however. A regular system of blocking out the ground is adhered to, as it should be. There will frequently be a tendency to lose the holes which are being put down in richer parts of the deposit. It would naturally be expected that these would contain more 'slips' and bad ground, and great difficulty may be experienced, therefore, in reaching to the full depth of the ore. But when such depths as can be reached have disclosed a sufficient quantity of ore of high enough grade to justify the inception of the enterprise, these areas may safely be left for later attempts at drilling, as experience has shown that additional reserves are always welcome, tending to greater economy by allowing an increase in the scale of working with a resulting lower unit cost. In the development of new enterprises of this character it may prove a question of much importance as to how long the beginning of actual construction work may be delayed waiting for the completion of exploratory work. This problem may solve itself at times, when the construction of mill and smelter in successive units automatically keeps step with the enlargement of ore reserve by drilling. In the case of the properties previously mentioned, the management has been extremely conservative in this regard, and those in charge of subsequent projects may well follow their example.

MINING

Practically only two types of mining methods are applicable to such deposits: (1) stripping and removal by steam-shovels when the deposit lies near the surface, and (2) some form of caving method when deeper seated. The latter methods have been developed in dealing with the iron ores of Lake Superior; their use in this connection has been so fully discussed elsewhere and their application to copper ores is so recent that no further discussion of them will be attempted here. Steam-shovel mining was also developed in handling the Lake Superior iron ores and has been applied with notable success in stripping and mining the 'porphyry coppers,' where with overburdens of one hundred feet or less in thickness and with three or more tons of ore uncovered per ton of capping handled, this method of mining is capable of yielding large daily tonnages at a low unit cost. While the two cases are not strictly comparable it will be of considerable interest to give some records of output at these mines and upon the Panama Canal. During June 1911 the No. 7 shovel of the Nevada Consolidated Copper Co. handled 74,000 cu. yd. of stripping. The No. 6 shovel handled during the same period 121,000 tons of ore (averaging 6% moisture) and 11,000 cu. yd. of stripping at an average cost of 15c. per dry ton of ore, and 34c. per cubic yard of stripping. The record upon the canal is held by shovel No. 257, a Marion, working in rock in a borrow pit on Gatun ridge, on the railroad relocation. This shovel during the six months of February to August 1911 averaged 62,864 cu. yd. per month, while the 40 shovels at work on the Central division during July averaged little more than one-half of this (1,314.8 cu. yd. per shovel per day), though showing an increase in daily output of 6.77% over that attained in 1910. The figures given are obtained by cross-section measurement in both cases. These shovels are of two sizes, 5-yard and 'class 70'; the Nevada Consolidated shovels are 5-yard, 95-ton Bucyrus shovels using 3½-yard dippers where the digging is hard, and those of the Utah Copper are Marion, Bucyrus, and Atlantic 5-yard shovels which have been fitted with 3½-yard dippers, as it is found that better service is obtained by decreasing delays by the lessened repairs. How much these amount to is evidenced by the fact that a shovel is actually engaged in the useful work of loading cars only about 40% of its time, the remaining 60% being occupied in trimming the face, moving back and up on account of blasting, advancing the tracks as work progresses, making minor repairs, and waiting for cars. The last is decreased by having an ample supply of cars and locomotives to move them. But it is not usually possible to cause the cars to follow a circular path, and the time required to run a loaded train out of the pit and run in the train of empties which has been waiting is frequently equal to or greater than the time required for loading. When other delays can be concentrated into this period the wait does not greatly matter, but it is obvious that the delays are likely to show an annoying tendency to get out of step and to make the stopping of the shovel necessary during the precious moments when the train is waiting to be loaded. Detailed costs of the steam-shovel work have not been made public by the mining companies, but we give below the statement of the average costs in the Central division of the Panama Canal for the three months of April, May, and June, 1911, as given in the *Canal Record*. These costs are based upon 4,186,518 cu. yd. handled during the period, or approximately twice the yardage handled by the Utah Copper Co. in the same time. It can scarcely be necessary to add that costs are not strictly comparable in the two cases, but the figures will serve to show the important factors in the work.

	Cents per cu. yd.
Drilling	5.42
Loading	5.04
Blasting	6.76
Tracks	8.14
Transportation	7.47
Dumps	4.42
Pumps	0.56
Maintenance and equipment	9.78
Plant, arbitrary	10.00
Division expense	1.17
Administration and general expenses	4.78
Total	63.48



STEAM-SHOVEL WORK, NEVADA CONSOLIDATED.

As noted above, the stripping cost at the Nevada Consolidated is given as 34c. per yard, but this undoubtedly does not include the last three items of the statement above, and it is impossible to rigidly compare costs in the absence of a detailed comparison of the conditions of work. At the Utah Copper the stripping cost is 33c. per cu. yd., which includes all items except the last three. It has been argued that it is not necessary to make an arbitrary charge for the amortization of plant, as repairs and renewals are included in maintenance, so that amortization would merely need to provide for the difference between the selling value and the book value of the plant at the cessation of operations. If this sum is actually set aside during the life of the property, preferably during its middle years, this plan has at least the advantage that it lightens the burden upon the first years of working when the working conditions are less favorable than at a later period.

It is impossible in the limited space at our command to take up a detailed analysis of all the features of this work; nor does it seem desirable to do so; yet some points should be briefly alluded to. The contour of the ground has an important influence on this work. It is necessary to carry on the work in successive benches, separated by slopes of a height and steepness varying according to the sum of the conditioning circumstances. In our issue of March 4, E. E. Barker discussed in detail this question of permissible slopes, concluding that under the conditions obtaining in the Copper Flat pit of the Nevada Consolidated the most desirable slope for economical operation is 1.75 to 1. The Utah Copper, having steeper natural slopes and greater differences of elevation counts, on using 1 to 1 slopes, and the high bank now carried on the edge of the big pit has a height of 250 ft. and a 50° slope, upsetting previous ideas as to the maximum permissible slopes. It is obvious that where the natural topography is steep it will be necessary to carry a large number of slopes, with a correspondingly great increase in the amount of trackage required, and of steep grades in order to reach the necessary elevations. On the other hand, some degree of compensation is found in the greater number of working faces afforded, thus allowing an earlier completion of the stripping of the orebody, and the more ample dumping ground for waste available upon a steep surface. As seen from the foregoing figures, the maintenance of tracks is a question of much importance; where these are greatly curved in the effort to 'make grade' the cost of the increased wear and the added delays due to derailments and other mishaps are a not unimportant factor. Drilling and blasting are carried on by separate crews, and the separation of capping from ore is effected by drilling through the capping until the ore is met, the capping is then blasted off, and the ore later drilled and blasted. The ore surface is a warped one, and in passing from capping into ore a working face will at some period be partly in one and partly in the other. This offers no difficulty where the transition occurs horizontally, as the ore may be loaded into one set of cars and the overburden into another, but where the dividing line occurs part way up the slope it is impossible to prevent the overburden from sliding down and becoming mixed with the ore as the latter is being removed. This is not a serious matter, however, as no ore is lost thereby, and even if 10% of barren waste should become mixed with the ore its total effect would be to decrease the grade of ore from 1.50 to 1.37% copper, for example. At Utah Copper not over 4 or 5% of waste containing copper is mixed with ore while mining ore next to capping, and after the capping is completely removed the ore will be mined clean. On the whole work this is of but slight importance, but in every case there will be a period during which the slopes are passing out of overburden into ore when this will assume an exaggerated temporary importance. In an ideal mine it would be easy to plan the work so as to minimize all the factors which militate against economy in steam-shovel mining, but in any actual case disturbing factors cannot be avoided. For example, it may be necessary to work at a disadvantage in order to obtain an immediate regular supply of ore for the mill and smelter, where greater economy in mining could be obtained by postponing the removal of ore until stripping was farther advanced. For this reason the ore supply at the Utah Copper has at present to be supplemented by ore broken underground at a cost approximately four times that of open-cut work. A portion of this extra cost will eventually be returned by the saving in drilling and blasting charges when the filled slopes are afterward mined by steam-shovel. This increased cost of mining of a portion of the ore may legitimately be regarded as a charge against the mill for keeping it in steady operation; in other words the cost of shutting down or operating the mill at part capacity is borne by the mine. It will readily be perceived that to an even greater extent than in ordinary mining the early operations are conducted at a disadvantage. Though the great capital expenditure for stripping is distributed over the life of the mine it necessarily, as a 'factor of safety,' imposes a heavier burden upon the early life of the mine when operating costs are higher than in the later work and the securing of the economies of full-scale operations are difficult.

The transportation of ores from the mines to the mills is an important factor in the cost of production, but it is so purely a matter of railroad operation that no discussion of it will be attempted here.

MILLING

It can scarcely be necessary to say that the problems of milling ore at the rate of ten thousand tons or more per day differ markedly from those arising in a small mill. In the former case large expenditures of capital for the purpose of reducing unit costs slightly, or for making a little higher saving, are advisable, and it may further be pointed out that the amounts of capital expenditure thus justified are much larger than might be expected without careful consideration. In milling, for example, an ore containing but 31 lb. of copper per ton, it will be obvious that a considerable saving will be necessary merely to defray the expenses of handling the ore. Suppose it is necessary to save 15 lb. per ton of the copper in order to defray operating costs. If the total saving is 18 lb. a certain profit will be made; if this saving can be increased 15%, or to 21 lb. per ton, an increase of 100% in the operating profit will be the result. Since, for example, the net operating revenue of the Utah Copper Co. during 1910 was nearly $4,000,000, the importance of this factor is easily grasped. For this reason careful study of the problems involved and intelligent modification of methods employed are not only possible, but necessary. It is not too much to say that milling practice at these large mills exemplifies the most advanced work yet done in the art of ore dressing. This is evidenced by the fact that a much higher recovery is made than previously deemed possible upon ores of this character, at an unexpectedly low operating cost. As the result of careful study the recovery has gradually been increased until, at the Arthur plant of the Utah Copper Co., it has reached at times as high as 77% and averages well above 70%, a substantial improvement on the first work done by this mill. As previously pointed out, this represents an enormous increase in operating profit, and would have justified a much larger expenditure of capital than was required to secure it.

The problem of milling these ores, though complicated in detail, is simple in its general features. To crush the ore as quickly and as cheaply as possible to a size which will permit the separation of ore and gangue, to make this separation as complete as possible with the fewest operations and machines and with the least possible production of slime, are the requirements for success. It is impracticable to attempt a separation of gangue and valuable mineral on material coarser than 10 mesh, on account of the fine state of division of the copper minerals. The coarse lumps are therefore crushed in gyratories and the whole mass reduced to 10 mesh by rolls, following the generally accepted practice. The coarse concentrate is then removed on roughing tables of the Wilfley type. The tailing is classified and the coarser portion of it is re-ground in Chilean mills to pass 40 mesh. The use of rolls for this re-crushing has been advocated upon the theory that they would make a smaller proportion of slime, but careful experiment has gone to show that the Chilean mills are more satisfactory for re-crushing material of this degree of fineness. The re-ground product is carefully classified, and like the former product, distributed to tables and vanners which are operated at a high capacity. This high capacity is made possible by careful classification and the classifiers must be regarded as machines of much importance in the mill work. Various types of classifiers have been employed, but the Richards-Janney has, so far, given the most satisfactory combination of capacity and refinement of product.

An important problem in milling is the loss of copper in material finer than 200 mesh. This is always more than half of the total loss, and would seem to be a strategic point of attack to secure an increase in saving. Unfortunately milling methods have, until recently, ignored this class of material, which is commonly designated as 'slime' and regarded as an impossible subject for treatment. Where its quantity and value are small this is a justifiable attitude, but where it represents the loss of millions of pounds of copper per year a closer scrutiny becomes necessary. Two lines of attack suggest themselves; to crush and separate the valuable mineral with the production of as little slime as possible, and to secure a better saving from the slime. The former method of attack has probably been pushed nearly to its limit in the mills of the Utah Copper Co., where practice in this regard exhibits a high degree of perfection. It is obvious that minerals cannot be separated in a coarse state which are present in a fine state of dissemination, nor can any ordinary ore be reduced to a fineness of 40 mesh by any known method of crushing without the production of large amounts of −200 mesh material.

Making a good recovery from material finer than 200 mesh is a disheartening task. That it is not an impossible one seems to be indicated by a screening analysis of the tailing from these mills, which shows that the tailing between 100 and 200 mesh has the lowest copper content of any. There seems no reason to believe that at 200 mesh an arbitrary line is overstepped, beyond which good recovery is impossible. But this may be looked at in another way; if the material approximately 200 mesh in fineness is low in its copper content, while all the material finer than 200 mesh shows a fairly high average, it follows that the finest material must have a proportionately high content of copper, or as it is ordinarily expressed, the copper minerals have 'slimed' in crushing. There is much difference of opinion over the proper definition of slime, but it may be defined for the present purpose as material which does not settle quickly. As the machinery used for making the separation of valuable minerals from gangue utilizes their relative settling ratio in some form or other, it is powerless to deal with material which will not settle.

MAGNA MILL, UTAH COPPER COMPANY.

Why will not fine material settle in water? The rate of settlement of solids in water depends chiefly on: (a) the relative density of the solids to the water; (b) the sizes and shapes of the particles; (c) the velocity of flow of the water; (d) the nature of the solids; (e) the ratio of solid to water; (f) the presence of electrolytes. The mass of the given particle is acted on by gravity, tending to make it fall in the water, while opposed by the various resistances indicated above. It is not clear at first why the size of the particle should affect its rate of settlement, but when taken in conjunction with the other factors the effect is clear. In dealing with a mineral particle consideration must also be given to what may be called its 'extraterritoriality,' an area immediately adjacent to the particle which exhibits phenomena as though it were actually a part of the particle. In other words, when a mineral particle falls through water the line of separation is not between the mineral and the water, but between the water which adheres to the mineral and the water through which this water-mineral aggregate is falling. This concept immediately introduces a highly complicated series of relations which are as yet imperfectly understood. Suppose there is a series of perfect spheres of equal size made of different minerals, will each sphere control an equal 'extraterritorial' area, or will they be unequal? And, in dealing with spheres of different sizes of the same material, will the ratio between mineral area and extraterritorial area be equal for all sizes? It is not known, but the weight of present evidence inclines to the belief that they are unequal in both cases. Accepting this view, it may result that with small equal sized particles of valuable mineral and gangue, the difference in extraterritorial area may so alter their relative settling ratios as to make a separation by any method based on settlement impossible. A further important point is the character of the solid. During fine grinding some of the minerals present are converted into colloidal hydrates and silicates, as pointed out by R. E. Ashley in the *Mining and Scientific Press* of June 12, 1909. It seems probable that these colloids attach themselves to the sulphide particles, much as oil does, the resulting aggregate having a structure similar to that of egg divested of its shell, the sulphide particles corresponding to the yolk and the colloids to the white. It is readily seen that this action would so increase the effective area of the sulphide particles as to militate strongly against their recovery by ordinary ore-dressing methods. Possibly the addition of milk of lime during crushing would be of service in preventing the formation of colloids. The effect of the presence of electrolytes has been studied in cyanidation, but little is known of its influence on ordinary ore dressing. Enough has perhaps been said to indicate that the problems involved in the milling of these copper ores yet requires much study and experiment. The operating staff is naturally jubilant over the securing of much better results than ever previously obtained; the management properly keeps its attention fixed upon the saving still to be made. Indeed, with tailing losses amounting to nearly three million dollars per year, this is a matter worthy of all the thought and experiment now being devoted to it. On the other hand, the old story of the superintendent who upon being asked why his recovery was not higher replied, "copper is the cheapest thing I've got," is not without its point. The line where an increased saving can be gained only at a cost which renders it profitless is a skirmish line which the technical staff of the operating companies is advancing as fast as practicable.

SMELTING

Smelting, refining, and selling the copper is of great importance, both because of the complexity of the operations involved and because it is the most expensive step in the series of operations. This is shown in the following table, deduced from the figures published in the annual reports of the Utah Copper Co. and the Nevada Consolidated.

	Cost of production in cents per pound. I.	 II.
Mining and development	1.01	1.83
Milling	1.92	2.08
Transportation	0.86	1.33
Smelting, refining, and selling	3.58	2.83
	7.37	8.07
Concentration ratio in milling	10 into 1	25 into 1

The relatively greater smelting costs in case I are due to the large tonnage smelted, the ratio of concentration in milling in the first case being approximately 10 into 1, and in the second 25 into 1. This, of course, is an individual problem, and the hasty generalization that the cost of production in case I might be decreased by increasing the ratio of concentration cannot be so quickly arrived at. The percentage of valuable mineral saved is now about the same in both cases; by increasing the concentration in case I the percentage of saving would be decreased. Furthermore, it is necessary to keep the requirements of the smelter in mind, whether to obtain the minimum rate from a custom smelter or to furnish a suitable product to the privately owned smelter.

Improvements in smelting methods have developed almost independently of methods of mining and milling, except so far as the problem of handling enormous tonnages of fine concentrate has circumscribed progress. The improvements in reverberatory practice have now practically settled the discussion as to the relative merits of blast-furnace and reverberatory carried on in the columns of the *Mining and Scientific Press* during 1906. It is now recognized that each has its proper field, and the handling of fine is clearly the field of the reverberatory furnace. The various methods for sintering or aggregating fine have been practically abandoned in the copper-smelting field, except as aids in the handling of flue-dust in some cases. How great recent progress in smelting has been may be graphically and not inaccurately indicated by saying that where formerly the effort in reverberatory smelting and in converting was to keep the furnaces and converters hot enough to keep the process in satisfactory operation, now the effort is to prevent them from becoming so hot that they are destroyed. In the case of the reverberatory this has been brought about by improvements in the method of firing and in furnace construction. The draught has been increased to nearly two inches of water, the furnace built so as to exclude unnecessary air, and the fires so placed and managed as to keep the greatly increased hearth area uniformly hot from end to end. This elevation of working heat-level would quickly result in the destruction of the furnace were it not for the frequent and copious feeding of charge at the hearth end, which rapidly smelts and is drawn off as matte and slag. The situation is not unlike that of a man who daily pays large sums into his bank, giving checks for nearly equal amounts, so that his actual balance, which in this case corresponds to the margin of safety between rapid smelting and destruction of the furnace, is actually small. The increased working temperature allows the raising of the roof, which formerly was kept close to the hearth in the effort to keep the heat down where it would do useful work, with the result that it was frequently burned out. The silica brick have been increased to 15 and 20 in. in length with good results.

Only two fuels are employed in reverberatory practice, coal and oil. Coal-dust firing, which was tried at the Highland Boy smelter at Salt Lake and at Cananea, has been discontinued, as was the use of regenerative gas-firing in Montana. In these cases it was found that these methods did not offer sufficient advantage under the then existing conditions to make it worth while to continue their use, but this should not be taken to indicate that the employment of coal-dust or gas-firing is contra-indicated in every subsequent case. Nor should it be hastily assumed that the great advantages of regenerative gas-firing in open-hearth steel practice can be easily reaped in reverberatory smelting; in the former case practically the only solid additions are steel scrap, in the latter the great quantity of solid fine works havoc in the regenerators. But this does not indicate that steel men and copper smelters cannot study each others' operations with profit.

Innovations are always regarded with enthusiastic approval, and the great advantages attending the use of oil as a fuel in reverberatory smelting are perhaps likely to be overestimated. The question of oil versus coal is actually a cold-blooded matter of dollars and cents. It is usual to reckon three to three and a half barrels of oil as equal to one ton of coal, which agrees well with results in practice; whichever of these is the cheaper, allowing for differences in cost of construction and maintenance, will be the fuel to employ. This will obviously be largely a matter of geography and friendly relations with transportation systems. Oil-firing offers the advantage that an auxiliary burner can easily be introduced into any part of the furnace in order to tide over a temporary emergency, but while great improvements have been made in the type of burners employed the damage to the roof has not yet been reduced to the point attainable in coal-firing. In both types of firing the heat utilized in the furnace is only about one-third that actually generated, the other two-thirds escaping to the waste-heat boilers, which should be of a type that permits easy cleaning. Probably little more than one-half of this is there utilized, so the combined efficiency of furnace and waste-heat boilers is something like 60 to 70%. But it must not be forgotten that there is no cheaper way to produce chimney draft than to utilize some of the heat of combustion for that purpose.

In converting, the most striking feature of recent progress is the wide application of the basic converter, which in copper metallurgy has long held the place occupied by the tariff in politics as a perennial topic of discussion. Recent articles have given in detail the construction of the Pierce-Smith basic converter and it is not our purpose to go beyond general features here. Basic converting is being successfully carried or in the ordinary type of converter, the general characteristic of the operation being that a large converter is employed, lined with magnesia brick, plastered with a magnesite-sodium silicate mixture, and so arranged that punching the tuyeres will not cause a destruction of the lining in that region. With these preliminaries everything is ready to add matte and silicious ore and go ahead. The silicious material is added in lump form; its addition in a finely divided state, though alluring, has proved difficult mechanically. A not unnatural question at this point is why, after the use of a basic lining has offered so much difficulty for so many years, it is now possible to employ it without difficulty. Various answers might be made to this; that it is now possible to prevent the destruction of the lining at the tuyeres, that a satisfactory inner lining to protect the expensive magnesia brick shell lining has been devised, and so on, but our personal opinion as to the real underlying reason is that now the converting operation is carried on with a sufficiently large active mass to give the necessary heat reserve—what may be designated as the working capital of heat—with a less temperature range. The losses are minimized by faster and more regular working and the heat is kept down by silicious additions. It was first thought necessary to pre-heat the lump ore added to the furnace, but this has been found not to be the case, and dry lump ore is now regularly used in converter practice. In the case of a custom smelter this is obviously a convenient method of smelting silicious ore.

It is not our purpose to go into the details of present smelting practice, and this discussion may well be brought to a close by pointing out that a smelter is a living organism and its life history, like that of all living organisms, consists of a series of adjustments to continually changing environment. Possibly the supersensitiveness of smeltermen to criticism, expressed or implied, in part arises from the too frequent ignoring of this truism and the setting forth of the excellencies of practice at a given place as though, like a patent medicine, they were universally applicable, and the pointing out of defects in practice without adding the qualification that the methods used represent the best that can be applied under the conditions.

* * *

LIGNITE is distinguished from sub-bituminous coal, according to E. E. Smith, in Bulletin 474 of the United States Geological Survey, by its color, texture, and amount of moisture. It is brown in color, or has a distinctly brownish cast. The texture is usually more or less distinctly woody, although some lignite, notably that of Texas, is amorphous. The amount of moisture ranges from 25 to nearly 45 per cent.

Valuation of Public Coal Lands

In response to a letter written by F. W. Mondell, representative from Wyoming and Chairman of the House Committee on Public Lands, the Secretary of the Interior has prepared the following statement regarding the present policy of the Government in valuing the coal lands before sale. Because of its particular interest throughout the West, it is published below in full:

Honorable W. F. Mondell,
House of Representatives

Sir: A reply to your letter of June 24, 1911, protesting against the present policy of valuation of public coal lands, has been delayed by my absence from the city, and by a desire to incorporate the latest data from official records. In your letter you state that the prices now being fixed on public coal lands are prohibitive, that they have paralyzed the coal industry of the West, that they have resulted in increasing the cost of coal to the consumer from 50c. to $1 per ton, and that they create a monopoly in the hands of the Government, and of those who acquired coal lands prior to the adoption of the classification policy. You also state that the prices in all the working fields run from $150 to $500 an acre, that millions of acres are rated at values above $180 an acre, that lignites are valued at hundreds of dollars an acre, and that the prices in the better fields are far in excess of those charged in commercial practice in the same fields or for the better-grade coals in the Eastern fields.

These statements are apparently based on a series of misapprehensions; first, as to the basis on which valuations are made by the Department; second, as to the prices which are actually placed on coal lands; and third, as to the effect which the classifications have had upon the sale of public coal lands.

There are estimated to be west of the 100th meridian 620 billion tons of anthracite and bituminous coal, 650 billion tons of sub-bituminous, and 720 billion tons of lignite. The valuation which the Department under the present scheme of classification places on any given tract of coal land is based primarily upon the tonnage and quality of coal which underlies that tract, so that the purchaser, instead of paying a flat rate per acre, pays by the ton for the coal which he buys, at values graded according to the character of the coal. Thus prices of lands underlain by anthracite and high-grade bituminous coals are computed at a maximum of 3c. per ton, whereas sub-bituminous coals of only moderate fuel value are rated at one-half cent per ton. An exception to the tonnage basis is made in the case of lignites and the lowest grades of sub-bituminous coals. Those are valued at the prices fixed by law as the minimum prices of coal land. No lignites are given values of hundreds of dollars an acre, nor any value greater than the minimum of $20 if within 15 miles of a railroad, or $10 if at a greater distance.

The tonnage values placed on coals are considered by no means unreasonable. The tonnage value for coal sold in the ground should be, in general, from one-fifth to one-half the royalty value of the same coal if paid for as mined, since the fee buyer has large risks and interest charges which a lessee has not. The price fixed under present regulations for a single bed of high-grade bituminous coal represents about one-fifth the computed royalty value of that bed, while values of additional beds, if more than one is present, are computed at much smaller fractions. For lower-grade coals the ratio of the Government sale price to the royalty values charged for the same coals in the same general region is still lower, being in some cases only one-fortieth and even less. The State of Colorado charges a royalty of 10c. per ton for coal mined from State lands, regardless of quality. Wyoming fixes royalties for all grades of coal mined from State lands at from 3 to 6c. per ton, depending upon the quantity produced. Private leases in Wyoming are reported at 10c., and for small local mines at royalties much higher. Fifteen cents is the royalty in the Miles City and Roundup districts of Montana, and the terms in the Trinidad and Boulder County fields of Colorado run from 8 to 27½c. The Government's price is in no case higher than 3c. per ton, and the great majority of the Western fields are being classified at from ½c. to 2c. per ton. No land is classified as coal land which is not underlain by a bed of a thickness and quality which has been commercially demonstrated to be workable in the United States. This system of valuation results in prices of which only a comparatively small part are $150 or more. Great areas are valued at the minimum, and other great areas at comparatively low figures. There cannot be millions of acres of classified lands rated above the figure you quote ($180) as "the highest price paid" by coal purchasers, since only 16 million acres of coal land have been priced to date. Values running into hundreds of dollars will be found only in the anthracite, bituminous, and very high-grade sub-bituminous fields, and in these only where the tonnage of coal is large.

In many if not most cases the prices fixed are less than the actual market price of private lands of the same character in the same fields. For example, coal lands in private ownership in the Rock Springs field, Wyoming, are reported to have been sold at from $180 to $430 an acre. The Government's prices in this field are from $20 to $465, the $465 price being for land with a greater tonnage than that covered by the land for which the $430 sale is reported. In the Colorado Springs district of Colorado sales of private land are reported at from $100 to $500. The classified prices in this district range from $20 to $50. It is true that some of the prices fixed by the Government are higher, acre for acre, than the prices asked for some of the highest grade coals of the Eastern fields, but the *greater tonnage per acre* in the Western fields makes the *value per ton* asked by the Government considerably less than that asked for even the low-priced Eastern lands. It must be remembered, moreover, that some of the Eastern fields are more remote from development or are subject to greater competition than many of the Western fields. The prices fixed in the most accessible and most active Western fields should not be compared with the lowest Eastern values, but with Eastern fields of the same accessibility. Lands in certain of the Pennsylvania fields are selling at $2000 per acre, whereas the highest price fixed by the Government on any of its lands is $608 per acre. The difference in quality between the coking bituminous coal of Pennsylvania and the non-coking bituminous coal of Colorado is more than compensated for by the fact that the Pennsylvania land in private ownership is sold on the basis of one bed of coal, and that less than 10 feet in thickness, whereas Government prices for the Colorado land refer to tracts underlain by four beds aggregating 23 ft. in thickness. The values for privately-owned lands in the Connellsville, Pennsylvania, district run as high as $300 per acre-foot. The highest Government price is $30 per acre-foot. It is plainly impossible that the net result of the classification policy has been to increase the cost of coal to the consumer from 50c. to $1 per ton, since the maximum Government price is only 3c. per ton.

Whether or not the prices fixed are prohibitive can best be judged from a study of the records of coal-land sales in the General Land Office. The following table shows that in the four fiscal years since the adoption of the classification policy the sales of public coal land have increased 12½% in acreage and 36% in value, as compared with the four fiscal years preceding July 1, 1907, and on inspection it will be noted in the table that during the first year of the four in which the reclassification has been in effect, the sales exceeded by 100% the average of the four years immediately preceding, but 1907 was the culmination of a period of industrial activity and boom conditions. In the fall of 1907 and during 1908 there was a sharp reaction from the somewhat inflated conditions of 1906 and 1907, and while there has been some recovery from the slump of 1907-8, the industrial situation is still far from satisfactory. During the last three years the production of coal has been in excess of the consumptive demand, and returns have not been remunerative to the producers. There has therefore been little to encourage the purchase of coal lands, and this condition easily explains the decreases in sales from 1907-8 to 1910-11. Moreover, largely because of uncertainty in the public mind during the past year regarding the stability of the Government's policy relative to public coal lands, and the feeling engendered by statements appearing from time to time in the public press, or referred to in public addresses, to the effect that the prices of Government coal lands should be lowered, prospective purchasers of such lands have been inclined to hold off. This hesitancy has naturally affected chiefly prospective purchases which were based on tentative speculation. On the other hand, legitimate locators who are proposing to proceed with actual development have been willing, after the lands in question have had prices placed upon them by the Government, to pay the prices assigned, since those prices are known to be based on very conservative tonnage estimates.

SALES OF COAL LANDS AT ALL PRICES

(Exclusive of Alaska)

Fiscal Year.	Entries.	Acres.	Receipts.
1903-1904	190	28,827.42	$ 395,309.90
1904-1905	158	20,456.35	277,402.40
1905-1906	244	42,143.39	538,683.70
1906-1907	157	20,387.02	303,255.60
Four years prior to July 1, 1907	749	111,814.18	$1,514,551.60
1907-1908	299	58,047.10	647,584.55
1908-1909	182	26,590.68	502,743.65
1909-1910	189	26,074.16	657,175.80
1910-1911	83	15,284.89	251,323.03
Four years since July 1, 1907	753	125,996.83	$2,058,827.03

TOTAL COAL LAND SALES AT VARIOUS PRICES SINCE JULY 1, 1907

Price per Acre.	Entries.	Acres.	Receipts.
$ 10.00	328	46,022.21	$ 461,099.33
15.00	15	2,310.55	34,658.25
17.50	1	40.00	700.00
20.00	258	52,833.03	773,028.80
25.00	37	11,171.68	131,671.70
30.00	23	3,159.81	94,794.30
35.00	2	239.78	8,392.30
40.00	8	800.06	32,002.40
45.00	...	240.00	10,800.00
49.00	1	40.00	1,960.00
50.00	69	8,218.63	409,023.00
65.00	...	200.00	13,000.00
75.00	2	161.23	12,092.25
90.00	1	121.69	10,952.10
92.00	1	40.00	3,680.00
100.00	1	38.48	3,848.00
120.00	1	40.00	4,800.00
135.00	1	80.00	10,800.00
140.00	1	120.00	16,800.00
170.00	1	39.89	6,781.30
180.00	1	40.00	7,200.00
270.00	1	39.79	10,743.30
Total	753	125,996.83	$2,058,827.03

Many of the lands sold since July 1, 1907, have doubtless been unclassified lands sold at the minimum price, but the table above shows that by no means all of the sales have been at minimum, and that the increase in sales for the four years is much more than equaled by the sales at classified prices greater than the minimum. In other words, the acreage sold at the minimum since classification began has actually been less than in the same period preceding, although the total acreage has increased, showing beyond question that the classification prices have not been prohibitive.

Although revenue for the Government is not the principal object to be attained in the classification of coal lands, it is worthy of note in the table just given that the sales at classified prices represent a clear gain to the public treasury of at least $407,134.50, and probably considerably more. This increase in revenue goes into the Reclamation Fund and is returned to the people of the West through the construction of reclamation projects.

Since the figures given above show that the prices fixed by the Department do not lessen the rate of sale of public coal lands, it follows that the classification policy neither injures the coal industry of the West nor creates a monopoly of coal lands in the hands of those whose title antedates the beginning of the classifications. The present healthy condition of the Western coal trade, in a region where the title to a large area of coal land still rests in the Government, as compared with conditions in the East, where the trade is unaffected by the public coal-land policy, is shown by the fact that the coal production of the Rocky Mountain States was 14.7% greater in 1910 than in 1909, although for the whole United States the increase in production for the same period was only 8.85%. The prices now fixed are designed, not to create monopoly in the hands of present owners of coal land, but to prevent monopoly by making it unprofitable to purchase large areas for indefinite holding without development. This, in fact, is the constant aim of the Department in the prices which it puts upon public coal lands—to make them low enough so as to encourage purchases for immediate development, yet sufficiently high so as to discourage purchases for long-time holdings for speculation or for monopolization. Prices prohibiting development would be inimical to the present interests of the people of the West; prices permitting purchase with a view to monopolization would be inimical to their future interests. The sole object, therefore, is to so value the lands as to permit development and to prohibit speculation.

In view of all the facts, however, I am convinced that the prices now being placed on the public coal lands are neither unreasonable nor exorbitant, and that the increase in the sale of coal lands for the four-year fiscal period subsequent to July 1, 1907, in comparison with the preceding four-year period, together with the present condition of the Western coal industry, demonstrate conclusively that the present classification policy is not open to the criticism you make.

It may well be that a liberal but wisely protected leasing law would be found to promote development more vigorously than any system of outright purchase. Such has been the case in Australia and New Zealand; and Canada has adopted the leasing system in its Yukon territory. It relieves the coal operator from the large capital expenditure of which you complain, and absolutely requires development as a condition of the lease.

Very respectfully,
WALTER L. FISHER,
Secretary.

Kansas City, Missouri,
September 27, 1911.

ACCOUNTS so far published show that the geology of the Porcupine district is essentially similar to that of Opasatica, and the gold occurs in similar quartz-ankerite veins. Tellurides have not yet been discovered at Porcupine, but it has been reported that some apparently unpromising veins have yielded good assays, which may be due to the presence of tellurides. In other veins the free gold at the surface has been found to continue in slightly increasing quantity down to depths of 200 ft. If this represents the zone of oxidation, then an enriched zone may be expected not far beneath.

Nevada Metal Production in 1910

The total value of the mine output of gold, silver, copper, lead, and zinc in Nevada in 1910, according to V. C. Heikes, of the United States Geological Survey, was $34,152,148, as against $30,072,932 in 1909, showing an increase of $4,079,216, or over 13.5 per cent.

The total production of gold in 1910 was 913,265.05 oz., valued at $18,878,864, a gain of $2,638,901, or 16%, over the 1909 production. Of the gold output 7851.70 oz. came from placers (mainly in Nye county), 880,180.93 oz. from silicious ores, 21,230.87 oz. from copper ores, and 3998.55 oz. from lead, zinc, copper-lead, and lead-zinc ores. Silicious ores yielded over 96% of the entire gold production. From bullion in gold and silver mills was recovered 728,139.67 oz., concentrate produced 76,696.62 oz., and crude ore shipped to smelters contained 100,574.06 ounces.

The largest production of gold was from Esmeralda county—$11,994,338 in 1910, against $10,341,397 in 1909. Of this production the Goldfield district yielded $11,137,150, an increase of $1,753,889, or 15.7%, over 1909. Nye county produced $3,661,967 gold in 1910, against $2,945,942 in 1909. The Tonopah mines yielded $2,303,702 gold, an increase of $903,341, or 64.5%, over 1909. The Comstock mines produced $502,843 gold, against $556,621 in 1909.

The silver production of Nevada in 1910 was 12,479,871 oz., valued at $6,739,130, against 10,981,061 oz., valued at $5,710,152, in 1909. Of the 1910 output 11,763,012 oz., or 94%, came from silicious ores, 583,282 oz. from lead ores, and 107,365 oz. from copper ores. Bullion at gold and silver mills produced 6,518,976 oz., concentrate 2,577,203 oz., and crude ore sent to smelters contained 3,380,037 oz. Nye county produced 10,550,303 oz. of silver in 1910, as against 8,246,496 oz. in 1909. Of this output the Tonopah district yielded 10,422,869 oz., or 83.5% of the entire silver production of Nevada in 1910. Storey county (Comstock) produced 320,716 oz., against 501,625 oz. in 1909.

Copper production increased in Nevada from 57,964,477 lb., valued at $7,536,942, in 1909, to 64,359,398 lb., valued at $8,173,643, in 1910. This increase was practically due to the mines at Ely, in the Robinson district, White Pine county, which yielded 63,914,197 lb., or 99.3% of the entire State production. Concentrate production 62,432,779 lb., and crude ore sent to smelters produced 1,926,619 pounds.

The production of lead in Nevada in 1910 was 4,871,130 lb., valued at $214,329, against 9,840,791 lb., valued at $423,154, in 1909, a decrease of about 50%. The mines of Clark county, the largest producer, yielded 1,309,684 lb., an increase of 863,777 lb. over the 1909 production. The mines of Eureka county produced only 672,801 lb., against 4,346,535 lb. in 1909, a decrease of 3,673,734 lb. Crude ore shipped to smelters contained all but 190,932 lb. of the total lead output of Nevada in 1910.

The zinc production of Nevada was 2,707,071 lb., valued at $146,182, in 1910, against 3,013,352 lb., valued at $162,721, in 1909. The entire 1910 production was derived from Clark county from ores shipped to smelters.

There were 608 mines producing gold, silver, copper, lead, or zinc in Nevada in 1910, compared with 417 in 1909. The total quantity of ore sold or treated in Nevada in 1910 was 3,655,775 short tons, an increase of 673,168 tons.

MINE PRODUCTION OF GOLD, SILVER, COPPER, LEAD, AND ZINC IN NEVADA IN 1910, BY COUNTIES

[By Victor C. Heikes, U. S. Geological Survey.]

Counties.	Ore treated, Tons.	Gold.*	Silver,* Fine ounces.	Copper, Pounds.	Lead, Pounds.	Zinc, Pounds.	Total value.
Churchill	1,164	$43,062	162,541	2,417	31,602	....	$132,531
Clark	33,640	219,191	30,650	216,773	1,309,684	2,707,071	467,080

*Includes placer production.

Gearing Construction

Metallic gearing, especially steel, is noisy in operation, the noise becoming particularly troublesome in the case of high-speed gear trains. Iron or brass gearing also has not sufficient elasticity to successfully withstand the shocks or back lash caused by the torque variations incident to the operation of machine tools such as punches, shears, and planers. In order to overcome these drawbacks, various kinds of non-metallic substances, such as rawhide and paper, have been used for one or more members of a gear train, but the results have been only partly successful. As a rule, pinions made of such substances were not sufficiently resistant to moisture and exposure to heat, and rawhide is liable to injury by rats and mice when kept in stock.

In cloth pinions these defects are obviated because of the nature of the material and the method of construction employed. The blanks from which the pinions are cut consist of a filler of cotton or similar material confined, at a pressure of several tons to the square inch, between steel shrouds, or side plates, the whole being held together by means of rivets, or, in case of very small pinions, by threaded sleeves. After the teeth are cut, the cloth filler is impregnated with oil. Cloth pinions are impervious to moisture, unaffected by changes in atmospheric conditions, and absolutely vermin-proof.

The teeth are cut to the 14.5° involute system according to Brown & Sharpe's standard. Diametral pitch is the standard of measurement, and companion gears should be cut to similar form. The teeth are stronger than those of any other type of non-metallic pinion, and are sufficiently elastic to allow the meshing teeth to bear evenly across the full width of face, thereby enabling the combination to absorb shocks capable of fracturing cast iron or brass. The pinions are self-lubricating, operate noiselessly, and have long life. Cloth pinions made by the General Electric Co. and operated under severe conditions for periods ranging from a few months to two years, have not shown any appreciable signs of wear.

Giant Gold Dredges at Natoma, California

By Newton Cleaveland

During the year 1911 the Natomas Consolidated of California has begun operating two new modern gold dredges of the California endless-chain type, having digging buckets of 15 cu. ft. capacity. These are known as Natoma 8 and Natoma 9. The machines dig to a depth of 55 ft. below the water-line. They have a maximum theoretical capacity of about 650 cu. yd. per hour, and have, under favorable conditions, handled 500 cu. yd. per hour of running time in continuous operation in formation extremely difficult to handle. They are the latest and most improved gold dredges in operation today, not only being the largest in capacity, but also having the most complete equipment. Something of their size may be inferred from the following list of materials used in the construction of each.

TUMBLER, NATOMA 8.

BOW VIEW DURING CONSTRUCTION.

	Weight, Pounds.
Lumber in hull and housing (732,000 bd. ft.)	2,196,000
Hull material (bolts, rods, nuts, and washers)	334,124
Nails and screws	21,574
Paint	8,266
Oakum	12,824
Dredge machinery	1,883,592
Pumps and piping	42,224
Wire rope and belts	50,601
Motors, transformers, and electric wiring and fittings	91,657
Total	4,640,862

Hull.—The hull has a total length of 150 ft., the beam is 58 ft. 6 in., with 5 ft. of deck overhang on either side, making 68 ft. 6 in. width of housing. The depth is 12 ft. 6 in. The well in which the digging ladder works is 82 ft. long. In all 732,000 bd. ft. of lumber was used in the construction of each of these hulls.

The Digging Ladder is 119 ft. long, of plate-girder construction, and weighs 210,740 lb., exclusive of ladder, rollers, and attachments. The upper tumbler body is a single high-carbon steel casting, and weighs 35,495 lb. with the shaft and cushion plates. The upper tumbler shaft is a hollow-bored, forged, nickel-steel shaft, 25 in. diam. at the centre, and is 14 ft. 11 in. long. The cushion plates are of chrome nickel steel, and are securely bolted to the tumbler. The lower tumbler body is a single casting of high-carbon steel, weighing 25,000 lb. with the shaft. The lower tumbler shaft is of 15¼ in. diam. by 7 ft. 8 in. long, and has a 4⅞-in. hole passing through its centre, through which the tie-rod passes. This tie-rod prevents the spreading of the lower end of the ladder under the pressure which it is obliged to support.

The Digging Buckets are 90 in number, and arranged in a close-connected line, each bucket having a digging capacity of 15 cu. ft. Each bucket is made up of three sections, a bottom, hood, and lip. The bottom is made of high-carbon steel, with an insert plate of manganese steel fitted in a cored recess under the back eye. The hood is made of ½-in. steel plate, pressed to the required shape. The lip is a manganese-steel casting 2¼ in. thick on the cutting edge, and 13 in. wide. These parts are all properly and securely riveted together, making the complete bucket, which weighs 3700 lb. approximately. The bucket pins, 90 in number, are made of high-carbon steel, finished 7⅜ in. diam. and 33 in. long. They are oil tempered and annealed, and weigh (approximately) 445 lb. each. The bucket bushings, 184 in number, are of manganese steel. The ladder rollers, 17 in number, are 16 in. diam., and together with the bearings weigh 52,330 lb. The entire weight of the digging ladder, bucket line, upper and lower tumblers, and ladder rollers is over 350 tons, distributed as in the following table:

	Pounds
Digging ladder	210,740
Upper tumbler and shaft	35,495
Lower tumbler and shaft	25,100
90 buckets, pins, and bushings	378,065
Ladder rollers and bearings	52,330
Total	701,730

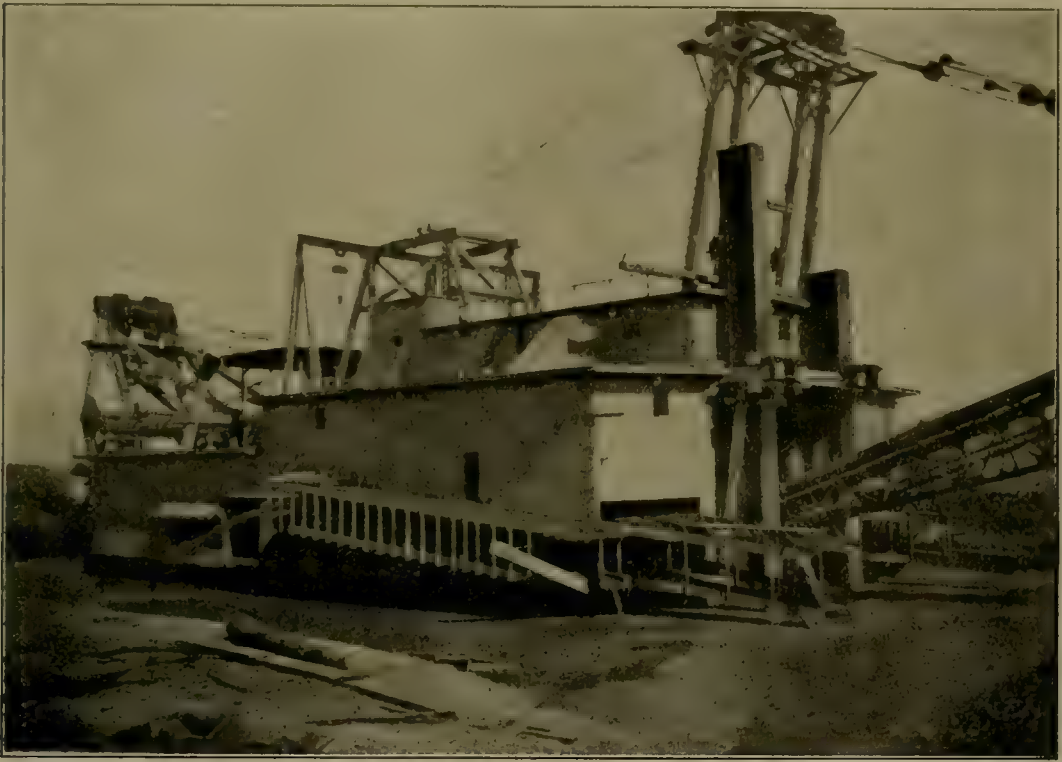
The upper tumbler shaft is driven at both ends through a double train of cast steel gearing. The total weight of this main drive is 59,322 lb., exclusive of tumbler and shaft.

The Main Hopper, into which the buckets dump, is built of ½ in. plate steel, and the discharge spout, lined with a cast manganese wearing plate 1½ in. thick, weighs 17,003 lb., and conveys the material from the bucket-line to the revolving screen. This is 9 ft. diam. by 50½ ft. long, and is lined with ⅝-in. high-carbon steel plates, with holes tapering from ⅜ to ½ in. throughout its surface. It weighs 111,921 lb. The screen-drive mechanism is of the single-friction roller type, and weighs, complete, 26,064 lb. The stacker hopper, which delivers the material from the lower end of the screen to the conveyor belt, weighs 5072 lb. The stacker ladder is of latticed-girder type, built of steel plates and angles, and is 142 ft. long. It carries the conveyor belt, which conveys and stacks the tailing in a pile beyond the stern of the boat, and together with the idlers and bearings weighs 40,410 lb. A 60-hp., 2000-volt, variable-speed motor is used to furnish power to run this conveyor belt. The bucket idler, for taking up the slack of bucket-line when in operation, and protecting the sides of the well, is unusually massive. On the sides of the well, in which the digging ladder works, are a set of ladder-roller girders, weighing 16,056 lb., that prevent damage to the well from the ladder.

The Spuds, 2 in number, are built of steel plates and angles, and each spud has a cast steel point, weighing approximately 21,000 lb. Each spud is 38 by 60 in. and 70 ft. long, and weighs 89,097 lb., including the spud point, or over 44 tons. Two steel castings, one for each spud, are attached to the stern of the dredge for distributing pressure from the spud over the stern. Each of these castings weighs approximately 18,300 pounds.

The Ladder Suspension Tackle is double in type, that is, there is a pair of six sheave blocks, 48 in. diam., on each side of the digging ladder. These sheaves revolve on steel pins 8½ in. diam. The forward hanger bars are of forged steel links, and the rear hangers are in two sections. The tackle weighs 118,280 lb., and is made of extra size and strength for the purpose of providing sufficient material and strength on either side of the ladder, to sustain it should the other side give way. The stacker suspension is from the rear gantry cap through a set of sheave blocks of six sheaves each, and 0.30 in. diameter.

Winches. The ladder hoist winch, consisting of one double drum, gears, shafts, bearings, and clutches, and mounted on a cast iron base, weighs 67,016 lb. The swinging winch consists of 8 drums with suitable gearing and friction clutches, is mounted on a cast iron base, and weighs 34,193 lb. The stacker hoist winch, the drum of which is cast steel driven through a set of worm gearing—the worm of steel and the worm wheel of bronze—is mounted on a rigid cast iron sub-base, and weighs 3732 lb. The arrangement of operating levers, quadrants, reach-rod, bell cranks, shafts, and bearings are so placed that the entire operation of the dredge may be conveniently controlled by one man in the winch room.



STERN VIEW, SHOWING OUTSIDE SLUICES, SPUDS, AND STACKER.

The Gold-Saving Tables, of a double-bank type, have an approximate area of 7000 sq. ft. of table surface. The arrangement is as follows: (1) 14 transverse sluices, 2 ft. 8 in. wide and having a grade of 1¼ to 12 in., built on each side of the dredge, which discharge into 10 longitudinal sluices of the same width on a slope of 1⅛ to 12 in., and extend to about 5 ft. aft of the stern line; (2) 84 trays so placed between the upper and lower bank of tables that all the material passing from the upper to the lower bank passes over them, thus giving about 600 sq. ft. of additional table surface. This gives approximately 7600 sq. ft. of riffled table surface for the collection of gold.

Tail Sluices, for discharging sand at the stern of dredge, are so arranged that the sand can be discharged far enough astern not to interfere with the operations of the dredge, or it may be discharged close to the spud if desired. These sluices are constructed of ¼-in. steel plates, and are so arranged that the plates may be removed when worn out.

The Save-All, placed at the rear of the well and under the bucket idler, and covered by the grizzly, to prevent damage from large rocks or heavy material that escape from the buckets as they dump into the hopper, is an extra gold-saving table of limited area, that recovers the gold from such material as passes through the grizzly bars, and which would otherwise drop directly into the pond and be lost.

Pumps.—Four pumps are in use on each boat for supplying water for the washing of gravel, both in the revolving screen and in the gold-saving tables, as well as for fire and other purposes.

The weight of the pumps, with the necessary piping, is 42,224 lb. They are:

No.	Size, inches.	Type.	Capacity, gal. per min.	Head, feet.
1	14	Centrifugal	5500	70
1	14	"	5500	40
1	6	"	700	120
1	12	Monitor		

Electrical Equipment.—Nine motors are needed to operate the dredge, aggregating 1072 hp., distributed as follows:

No.	Hp.	Volt.	Type.		Use.
1	400	2000	Variable	speed	Main drive
1	30	2000	"	"	Winch
1	150	2000	Constant	"	70-ft. head pump
1	75	2000	"	"	40-ft. head pump
1	30	2000	"	"	5-in. pump
1	75	2000	Variable	"	Screen drive
1	60	2000	"	"	Stacker drive
1	2	110	Constant	"	Tools
1	250	2000	"	"	Monitor pump

A three-panel switch-board, placed in the winch room, together with its wiring, completes the electrical equipment of the dredge. The weight of the motors and transformers is 75,057 pounds.

The Wire Rope required for construction and operation is a total of 8760 ft. or 1⅔ miles, weighing approximately 35,317 lb., and distributed as follows:

Construction.	Diam. in.	Number req'd.	Length each, ft.	Total length, ft.
Bow gantry guys	2½	2	239	478
Stern gantry guys	2	2	135	270
Tail sluice support	½	2	250	500
Foot bridge suspension	½	2	250	500
Stacker sling	2	1	172	172
Stacker guys	1	2	120	240
				2160
Operation.				
Ladder hoist	1½	2	1200	2400
Stacker hoist	1	1	600	600
Spud hoist	1	2	600	1200
Bow swing	1¼	2	700	1400
Stern swing	1	2	500	1000
				6600

The Belts required for operation are as follows:

	Width, in.	Length, ft.
Conveyor belt	42	275
Ladder hoist	32	60
Main drive	32	80
Winch	16	50
Screen shaft	14	50
Screen motor	18	60
Stacker hoist	6	40
Total		340

The first successful dredge in California started operations on March 1, 1898, on the Feather river, near Oroville, and had a monthly capacity of 40,000 cu. yd. A comparison between this boat and the one herein described may be of interest.

Started.	Bucket cap., cu. ft.	Hull dimensions. ft.	Power used, hp.
March 1, 1898	3½	80 by 30 by 7	63
August 10, 1911	15	150 by 58½ by 12½	1072

Institute Meeting Provisional Program

Detailed programs for the week of meetings in San Francisco and excursions in the vicinity, arranged for the American Institute of Mining Engineers, will be available at headquarters in the St. Francis hotel Tuesday morning, October 10. Sessions for reading of papers and for discussions will be held Tuesday afternoon, Wednesday forenoon, and Thursday forenoon. Evening sessions will be arranged if desired. The list of papers promised is:

Historical Sketch of the Mining Industry of Japan, by K. Nishio.

The Laramie Tunnel, by D. W. Brunton.

Notes on the Liberty Bell Mine, by C. A. Chase.

California Oil, by Mark L. Requa.

Progress in Electro-Amalgamation, by S. B. Christy.

Notes on the Geological Structure of Tonopah, Nevada; Classification of Ore Deposits for Miners, by Augustus Locke.

The Laws of Igneous Emanation Pressure; Physical Data of Igneous Emanation, by Blamey Stevens.

Electrolytic Oxygen in Cyanide Solution, by T. H. Aldrich, Jr.

Fuel Problems of the Pacific; Government Coal Mines in the Philippines, by Oscar H. Reinholdt.

The Black Mountain Coal District, Kentucky, by J. B. Dilworth, with discussion by J. Langdon.

Reminiscences of the Beginning of the Institute, by R. W. Raymond.

Some Features of Replacement Orebodies and the Criteria by Means of Which They May Be Discovered, by J. D. Irving.

Slime Filtration, by Geo. T. Young.

A Modification of the 'Gay Lussac' Method for Silver Bullion Containing Tin, by E. J. Hall.

Geology of Some Mines in South of Colombia, S. A., by F. P. Gamba.

Vadose Ore Deposition in Arid Regions, by C. R. Keyes.

Biographical Notes on S. F. Emmons, by G. F. Becker.

Electrolytic Refining at the U. S. Mint, San Francisco, by E. B. Durham.

The Fritz and Coxe Laboratories, by J. Daniels.

Rapid Estimation of Available Calcium in Lime Used in the Cyanide Process, by L. W. Bahney.

Phosphorus in Coking-Coal, by Charles Catlett.

Electrical Practice in Mines, by Burton McCollum.

Geology and Operation of the Newport Mine, by B. W. Vallat.

Mineral Production and Resources of China, by T. T. Read.

Rational Valuation and Quality Efficiency of Furnace Stock, by J. J. Porter.

Cyanide-Plant at the Treadwell Mines, Alaska, by W. P. Lass.

The excursion Wednesday afternoon will be to Stanford University, Thursday to the University of California, Friday to Natoma, and Sunday to the Bohemian Grove. Members of the Institute and the immediate members of their families are invited to participate. Saturday will be devoted to the exercises incident to beginning work on the Panama-Pacific exposition, and Monday to short excursions to the Mint and other points of interest in and around the City. A cordial invitation has been extended to members to visit the plants of the following companies: Columbia Steel Co., George E. Dow Pumping Engine Co., The Paraffine Paint Co., Selby Smelting & Lead Co., A. Schilling & Co. Arrangements will be made for small parties as desired.

American Institute of Mining Engineers

PROPOSED AMENDMENTS TO THE CONSTITUTION

The Board of Directors and the Council of the Institute, after careful deliberation, has unanimously recommended to the Institute revisions and amendments to its Constitution, embodying changes which are considered necessary for the immediate and the permanent welfare of the organization. These amendments will be presented for action at the next annual business meeting February 20, 1912.

The change of name, to the 'American Institute of Mining and Metallurgy,' is proposed as a tardy recognition of the fact that since its foundation the Institute has been not only the distinctive mining society of America, but also the metallurgical society of America. It is obvious from an inspection of the Institute's Transactions that its field of activity has been, in fact, largely metallurgical.

The re-classification of membership is submitted because the existing classification does not meet the requirements of present conditions, and a strong sentiment has developed for such a re-classification as will raise the standard of membership. The increase of dues of *corporate members* to $15 per year is proposed partly in order to enable the Institute to offer its advantages to the younger *junior members* at a lower rate, and partly to enable it to extend its field of useful activities; moreover, this increase in full members' dues has long since been found absolutely necessary by all the other national engineering societies. In order that opportunity may be afforded for informal discussion of the proposed amendments during the progress of the San Francisco meeting the more important articles are given in full below.

ARTICLE II

Section 1.—The membership of the Institute shall, after September 1, 1912, be divided into four classes, namely: (1) *corporate members;* (2) *honorary members;* (3) *associate members;* and (4) *junior members.* Only members of the first class *(corporate members)* residing within the United States of America, Republic of Mexico, or Dominion of Canada, shall be entitled to vote or hold office.

Section 2.—The first class, or *corporate members*, shall comprise all members of the Institute as the same existed prior to September 1, 1912, who shall not, at their own request, have been transferred to the class of *associate members* or the class of *junior members;* and all persons who shall thereafter be transferred to or elected to membership in this class. The second class, or *honorary members*, shall comprise the present *honorary members* of the Institute and such persons as shall hereafter be elected to such class. The number of *honorary members* shall not exceed twenty-five. The third class, or *associate members*, shall comprise all the *associates* of the Institute except such as may, upon presentation to the committee on membership before September 1, 1912, of satisfactory evidence of their qualifications for transferral into the class of *corporate members,* be duly enrolled in the class of *corporate members;* and such persons as shall thereafter be elected *associate members.* The fourth class, or *junior members*, shall comprise such present members as shall, prior to September 1, 1912, express to the committee on membership their desire to become enrolled in the class of *junior members*, and present evidence of their qualifications to enter such class; and such persons as shall thereafter be elected to this class.

Section 3.—The following classes of persons shall be eligible for membership in the Institute, namely: As *corporate members,* all professional mining engineers, geologists, metallurgists, or chemists, and all persons practically engaged in mining, metallurgy, or metallurgical engineering. As *honorary members*, such persons of eminence and distinction as, in the judgment of the committee on membership, shall be deemed suitable. As *associate members*, all other persons desirous of being connected with the Institute who in the opinion of the Council, are suitable. As *junior members*, students of any of above professions or persons engaged in learning the same. The term of *junior membership* shall be limited to six years.

Section 4. Every candidate for election as a *corporate member*, *associate member*, or *junior member* of the Institute must be proposed for election, in writing signed by three members; must be approved by the committee on membership as directed in the by-laws; and must be elected by the Council. At least three fourths of the votes cast must be in favor of a candidate to secure his election. The membership of each person so elected shall commence upon the payment of his initiation fee and current dues, as hereinafter in Article III prescribed. Each person proposed for election as *honorary member* must be recommended in writing by at least ten members; must be approved by the Council, and must be elected by ballot at a meeting of the Board of Directors by unanimous vote of all the directors present.

Section 5.—If any person elected a *corporate member*, *associate member*, or *junior member* does not within sixty days after notice of his election, accept the same and pay his initiation fee and dues for the current year, his election may, in the discretion of the Council, be canceled.

Section 6.—The Council may at any time, for reasons which, to a majority of the members thereof, seem sufficient, change the classification of any *corporate member, honorary member, associate member*, or *junior member.*

ARTICLE III

Section 1.—The dues *of corporate members* shall, beginning with the year 1913, be $15 per annum, payable in advance on the first day of each calendar year. Each newly elected *corporate member* shall, when notified of his election, pay an initiation fee of $10, in addition to his dues for the current year; *provided, however*, that each *corporate member* whose residence or place of business is or shall be located within fifty miles of the headquarters of the Institute in New York City, shall, so long as he shall maintain such residence or place of business, pay $20 yearly dues.

Section 2.—The dues of *associate members* shall be $10 per annum, payable in advance on the first day of each calendar year. Each newly elected *associate member* shall pay, when notified of his election, an initiation fee of $10, in addition to the dues for the current year; *provided, however*, that each *associate member* whose residence or place of business is or shall be located within fifty miles of the headquarters of the Institute in New York City, shall, so long as he shall maintain such residence or place of business, pay $15 yearly dues.

Section 3.—The dues of *junior members* shall be $5 per annum, payable in advance on the first day of each calendar year. *Junior members* are not required to pay any entrance fee; but when the period during which any person shall be entitled to *junior membership* shall have expired, such person shall, upon being promoted to the class of *corporate members*, pay an initiation fee of $10, as well as the dues of a *corporate member* for the current year.

Section 4.—*Honorary members* shall be exempt from payment of fees and dues.

Section 5.—Any *corporate member, associate member*, or *junior member* who shall not pay his dues within one year after they shall become due, shall, unless otherwise ordered by the Council, be deprived of all privileges of membership, and if he shall continue in arrears for two years, his name shall be stricken from the roll of the Institute. Any person whose name shall have been stricken from the roll because of non-payment of dues and for no other reason, may be restored to membership by the Council on payment of all his arrears or may, after an interval of three years, be proposed for election on the same terms as any non-member.

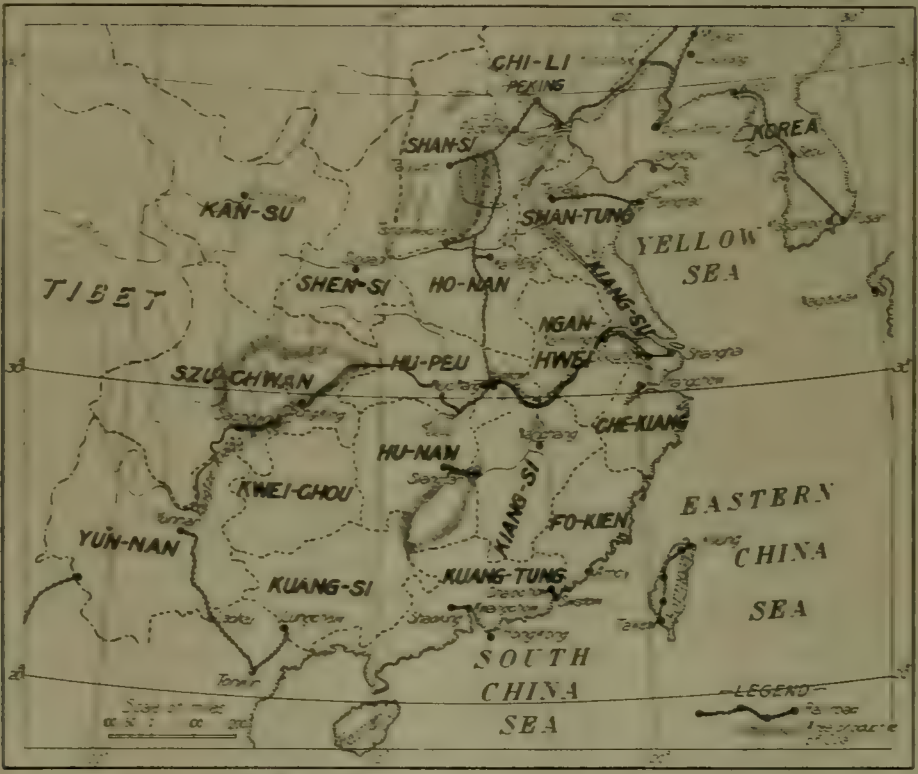
Section 6.—Any *corporate member* or *associate member* in good standing may, by the payment at one time of $250, become a *life member* or *life associate member*, as the case may be, and shall not be liable thereafter for any dues.

Mineral Production and Resources of China

By Thomas T. Read

*When so much has been written upon a subject on which so little definite information is available as upon this, some reason must needs be assigned for adding to the volume of literature. A sufficient reason is found in the probable great future importance of China as a producer of mineral wealth. The present undeveloped state of mining in the Empire is due to many causes, among which the most important are the relatively simple needs of the population, the lack of transportation facilities, the inelastic regulations governing the industry, and the superstitious reluctance of the people to make excavations which might disturb the spirits of the earth and air, or of ancestors.

Iron is the metal most in demand, yet the needs of the population, until recently, only made necessary a production of approximately 1½ lb. of iron per capita per year. The present annual production of iron for domestic consumption in the United States is nearly 600 lb. per capita. The curious state of development of transportation in China has been a greater handicap upon the mining industry than upon any other. The point upon which it hinges is the absence of a road system. Except for a few military roads, now almost impassable, there are no roads in China, that is to say, there is no land which is set aside as a right of way, belonging to the commonwealth. Throughout the agricultural districts, generally speaking, the entire area is in private ownership and the lines of travel are between fields. There is a constant struggle for existence between the owners of the land and the traveling public, with the natural result that the so-called roads usually are simply lines along which it is merely possible to travel. Most merchandise is carried in baskets over the shoulder, pushed in wheelbarrows, or transported on pack-animals, or in carts, to the streams. Really cheap and efficient transportation is confined to the rivers, and great ingenuity is exhibited in utilizing them to the fullest extent. On the Lan river, for example, the boats, to use an expressive colloquialism, "can float in a heavy dew." The regions where mineral wealth is abundant are naturally but poorly supplied with navigable streams, and it is only where Nature has been so kind as to gather together in one place all the materials necessary for the extraction and reduction of the minerals that any considerable industry has been able to develop. Now railroads are penetrating all parts of the Empire, the streets built in the cities are being extended as roads through the surrounding territory, and the mineral industry is taking on a new aspect.



MAP OF CHINA, SHOWING APPROXIMATE COAL AREAS.

Theoretically the mineral wealth of the Empire is the property of the central Government, and is only worked by permission upon a royalty basis. Practically this is difficult to enforce, and there have grown up relationships between the operators and the government which are complicated in the extreme. The development of the mining industry is correspondingly hampered, and it is hoped that a simple and direct code of mining regulations may be put in force at no far distant date. The importance of the superstitions regarding graves and 'Fêng-Shui' has been overemphasized. It has undoubtedly operated to restrict prospecting work, but where valuable deposits are found it is always possible to have graves moved for a reasonable sum, and it is but seldom that a regard for 'spirits' is allowed to operate to financial disadvantage. With the spread of education this factor will lose the limited importance it now possesses.

COAL

Coal is easily the first of the mineral resources of China.

---

*Abstract of a paper to be presented at the San Francisco meeting of the Amer. Inst. of Min. Eng., October 16 to 17.

The great extent of the deposits has already been indicated, and a conservative estimate of the present production is over 13 million tons annually. The casual visitor to North China, where the winter climate is rigorous, seeing the children of the villagers, armed with rake and basket, engaged in collecting every scrap of vegetable material that can be utilized as fuel, is likely to wonder why coal is not more generally used. The reason is not recondite; the low cost of labor, the high cost of transportation, and the low scale of living put coal beyond the reach of the population in many regions. It is probably safe to estimate that one half the cost of the food of an ordinary workman is chargeable to the fuel used in cooking it, and where the otherwise unemployed children can be sent out to gather grass and pull up the roots of the larger cereals, such as corn and *kao liang*, there is little market for coal, except for industrial purposes. Near mines, where coal is abundant and cheap, it is freely employed. The development of railroads, steamships, and industrial plants will not only create a greater market for coal, *per se*, but, by raising the scale of living through the higher wages paid for labor, will increase the consumption of coal for household purposes. The annual consumption of coal in the United States is approximately $3\frac{1}{2}$ tons per capita per annum; the consumption in China is approximately $\frac{1}{25}$ ton per capita per annum. An approximate estimate of the present coal production in China is given in Table I.

Other provinces	....	100,000	....
Total	6,140,000	5,900,000	1,150,000
Grand total	13,190,000		

The sketch-map on the preceding page shows in general the coal areas of China.

The coalfields of China were described in the *Mining and Scientific Press* of January 2, 1909, and the P'ing-hsiang colliery, one of the most important mines worked by modern methods, was described in detail in the *Mining and Scientific Press* of October 29, 1910. The coalfields of China may be briefly divided into six groups: (1) the Manchurian fields; (2) the fields of eastern Chili and Shantung; (3) the Shansi, western Chili, and northern Honan field; (4) the Hunan field; (5) the Ssu-chuan field; (6) the Yunnan and Kweichou fields. In all these fields coal is worked by primitive native methods; only small openings are made, which are temporarily held open by a scanty use of small timber, and the coal is dragged to the surface in baskets provided with iron or bamboo runners much like a sled. Working is confined to the parts of the seam which are comparatively dry; where water is met it is handled by bailing, or by a primitive type of pump. The number of native mines is very great and their aggregate production is large. The coal brings a very low price at the mine, and the larger part of the selling price in the large cities is chargeable to transportation. In the first four groups there are a number of mines worked on a large scale by modern methods; where they are favorably situated with respect to transportation good profits are made; the largest mines, at Tongshan and Linsi, Chili province, owned by the Chinese Engineering & Mining Co., having produced more than a million tons of coal in 1910 at a profit of a little over $1 per ton. For a more extended discussion of the coal mines of China, reference should be made to the original paper. In conclusion it may be said that the coalfields of China are of great extent, the coal is generally of good quality, and the fields are widely scattered, so that no parts of the Empire are far distant from the sources of supply. In extent and quality the coal resources of the Empire compare favorably with those of the United States. As a rough comparison it may be said that Chinese coals are slightly younger than those of North America, most of the fields being upper Carbonic or Permian. In the north Jurassic and Tertiary coals occur, but except for the Fushun field are of little importance as yet. There is a good deal of controversy over the exact age of these coals, but it is of little interest to mining engineers. Bituminous coking coal is very common; coke made by native methods can be obtained almost anywhere in the Empire. When made from washed coal the resulting coke is of excellent quality and will afford an abundant supply for the smelting industries which are likely to develop. The anthracite is of excellent quality, but the bituminous is often friable, yielding an excessive proportion of fine coal. When worked on a large scale this can, in many cases, be washed and converted into coke. The Chinese custom is to make the dust into briquettes with clay as a binder, which are dried and burned. In recent years the number of mines equipped with modern machinery has become comparatively great and the present supply amply meets the demand. The mines of the Fushun company and the Chinese Engineering & Mining Co. now chiefly supply the railway and shipping trade of North China, because of the superior transportation facilities which they enjoy. These two companies also send coal to the cities along the southeast coast, competing with Japanese coal. Coal production throughout China exhibits a healthy and vigorous growth. The annual production of the Empire, as shown in the tables, is estimated at over 13,000,000 tons, but this amount is only approximate. The amounts given for Yunnan and Ssu-chuan, for example, should be designated as guesses rather than estimates, and the figures occasionally seen in statistical tables giving the production of the Empire to the nearest thousand tons present a misleading appearance of accuracy inconsistent with the data upon which they are based.

IRON

Iron is the second in importance of all the mineral resources of China, and the security of the future of the Empire as a mineral-producing nation is easily appreciated, since it is founded upon an abundant supply of coal and iron, the two bases of industrial development. In the case of other minerals it may be inferred, without falling into serious error, that practically every occurrence of importance has been worked, to a slight extent at least, by native methods. But this is not true of iron deposits. The great importance of the lack of transportation facilities upon the development of mineral wealth has already been mentioned, and it is in the case of iron that its influence has been most marked. In the native method of iron-smelting such large quantities of coal are used that it is necessary to have both coal and iron ore in close

Note.—Analyses by Cheng-Fu Wang.

proximity in order to permit the development of a smelting industry. This condition obtains in several provinces, but most notably in Shansi, where it has been described by von Richthofen and Shockley. But while these deposits are adapted to the native methods of working, they are not at all suited to modern methods, where a large supply of ore of uniform quality and high iron content is necessary. It is reasonably certain that such deposits exist in numerous places, but, except in the case of the Ta Yeh mine, they have not yet been developed, because the necessary supply of coal does not exist nearby. I will first describe the P'ing-t'ing-chou district in Shansi, the principal one in which iron is produced by native methods. The accounts of this by von Richthofen have already been mentioned; what is here given, however, is based upon notes made during the winter of 1910. The analyses given of the raw materials and products have been made by Messrs. C. F. and C. H. Wang and F. N. Lu, three of my former students.

The iron ores of Shansi are limonite and hematite, occurring in shales and sandstones of Carboniferous age; the varieties of method of occurrence are so numerous that to attempt their description would require too much space. Usually they are in masses of no great size, commonly in or near a disturbed zone in the strata, or else in beds or flat veins, from a few inches to not over three feet thick, of limited extent. It follows, therefore, that no sufficient supply of uniform enough quality can be obtained from the Shansi deposits, so far as yet explored, to form the basis of blast-furnace work on a large scale. More recently it has been reported that on the southern border of this district, in Honan province, a suitable deposit has been found, and it has been proposed to erect there another government iron-works, similar to the one described later.

The ore, mined through shallow round or rectangular shafts (see illustration), is broken into small pieces and hand-sorted into several grades, which are sold to the smelting plants. Here it is mixed with 50% of its volume of coal and packed into cylindrical crucibles (see illustration) 5 in. inner diameter and usually 15 in. high. From 250 to 275 of these are set upright in a rectangular furnace, about 12 by 6 by 4 ft. Air space is secured at the bottom of this by a layer of broken crucibles over which is placed a layer of coal, then the crucibles are set in place, with coal between them; the front side is closed, the whole is covered over, ignited, and allowed to burn by natural draft for three days. The crucibles are then removed and the contents taken out. This operation usually involves breaking the bottom part of the crucible, which now contains an irregular 'bloom' of iron of very variable composition (see table of analyses), irregular fragments of iron, earthy residues, and a certain amount of coke. The bloom is sold to the makers of wrought iron, the small pieces of iron are sold to the makers of cast iron, and the coke is used in the manufacture of crucibles. It should be noted that the product of this method of smelting is not pig iron, in the ordinary sense of the word, as it contains very little carbon and is malleable. The bloom is worked into wrought iron by heating in a wood fire and hammering until it is worked down into a rectangular ingot, which is then sold, and either manufactured locally into various objects and utensils, or shipped in the ingot form to all parts of the Empire. The small pieces of iron are mixed with coal and placed in crucibles, about 7 by 14 in., and 50 to 80 of these are placed in a smaller furnace (see illustration) blown by hand. When the iron is melted the covering of the furnace is removed, the crucibles taken out, the contents of several crucibles are poured into one, and this is then poured into molds, which have previously been prepared with extraordinary skill. In this way various cooking utensils, especially *kuo*, are cast, often remarkably thin, as the castings contain as much as 5 to 7%

SHAFT FOR EXTRACTION OF IRON ORE.

of phosphorus which has been taken up from the coal during the reduction and re-melting. Note the high percentage of phosphorus in the cast-iron bar, analysis 12. It is the high phosphorus content of the Shansi coals (see analyses given) which has been the chief factor in the great development of the industry, as it has afforded an easy means of securing the high-phosphorus iron necessary in making thin castings. Formerly the iron products of this locality found their way through the channels of trade to nearly all parts of the Empire. Now the trade in native iron flourishes chiefly in the interior, as foreign scrap iron and steel, especially old horseshoes, are imported in large quantities into all the treaty ports, and because of their superior quality and low price tend to drive out the native product. The native industry, therefore, is steadily dwindling, though it will continue to exist until foreign cooking utensils displace the high-phosphorus cast-iron *kuo* and teapots. Shockley has called attention to the amount of decrease between the time of Richthofen's visit and his own. The annual production of the chief districts of Shansi, as estimated by Shockley, in 1901 was 51,248 tons.

The only modern steel works existing in China at present is the blast-furnace and steel plant of the Han-Yeh-P'ing Iron & Coal Co., situated at Hanyang, just across the Han river from Hankow, in central China. Its iron ores are mined at Ta-Yeh, about 50 miles southwest, and its coke is obtained from its colliery of P'ing-hsiang in Kiang-si province, more than 300 miles distant.

The iron ores at Ta-Yeh occur about 15 miles west of the Yangtze river, and lie along the contact between a marble and a large intrusive body of a dark gray syenitic rock. The ore is a good quality of hematite of about the following range of composition, furnished by the Han-Yeh-P'ing Iron & Coal Company:

	Iron ore, Ta-Yeh. Per cent.
Fe	60.00 to 62.00
P	0.05 " 0.25
S	0.05 " 0.12
SiO_2	3.00 " 5.00
Al_2O_3	1.00 " 2.00
Mn	0.20 " 0.40
Cu	0.05 " 0.25

At one place it is slightly magnetic, apparently having been partly reduced to the magnetic oxide by the action of reducing solutions which have deposited small amounts of copper and iron sulphides along the foot-wall. During the Ming dynasty efforts were made to work this deposit as a copper mine, but could scarcely have been very successful. The iron ore is developed over a length of more than two miles, but apparently is not continuous over that extent. The contact runs nearly east and west, and for considerable distances to each side of the present workings the ores can be traced. Where it is worked the orebody is about 200 ft. thick and is nearly vertical, dipping slightly to the north.

At the steel plant two blast-furnaces, each of 100 tons daily capacity, are in operation, and a third unit of 250 tons capacity has just been completed. Three Siemens-Martin open-hearth furnaces are in operation, two are under construction, and five more are projected. The rolling-mill has a capacity of 800 tons per day; the larger part of it is devoted to rolling railway material, as the greatest demand in China is for material of this nature. During 1909 there was produced 307,500 tons of iron ore, of which a large part was exported to Japan and America and the remainder smelted at Hanyang. Of the resulting pig iron, 44,300 tons was sold as such, and the remainder converted into 28,500 tons of steel, chiefly steel rails. Thirty-six hundred tons of manganese ore of good quality was produced in 1908 at P'ing-hsiang in the province of Kiangsi. In several other places the company owns deposits of manganiferous limonite which contains about 20% manganese, which can also be utilized, if necessary. The company has a contract with the Japanese Government iron works at Wakamatsu to supply them with ore of bessemer grade, and has recently made a contract with the Western Steel Corporation to furnish it yearly with 36,000 tons of ore and 36,000 tons of basic pig iron at its works at Seattle, Washington.

In Kiang-su province iron ores are widely distributed, occurring chiefly in the region about Nanking in association with the limestone previously mentioned. Richthofen seems to regard these of little promise because of the absence of coal of suitable quality in the neighborhood. But if the distance to which iron ores are transported in the United States is considered, and the fact that the ores in question are conveniently adjacent to the Yangtze river, it seems much more probable that these ores will be the next to be developed on a modern scale. The ore is probably of similar character to that at Ta-Yeh, previously described.

The cost of production of iron ore in the open-cut workings at Ta-Yeh is approximately as follows:

	Pesos per ton.
Stripping	0.08
Mining	0.18
Tramming	0.03
Powder, steel, etc.	0.015
Superintendence	0.06
Loading cars, freight to Yangtze, etc.	0.30

This would make the probable cost of the ore delivered at the blast-furnace a little over ₱1 per ton. The cost of limestone is about two-thirds of this; the cost of coke is ₱15 and coal about ₱8. These low costs are largely due to the low cost of labor. Ordinary unskilled labor receives from 200 to 300 cash per day or 8 to 12c. Skilled labor receives from ₱10 to ₱50 per month, and the efficiency of this labor is remarkably high. As a result pig iron and steel can be produced at a low cost, and the company at Hanyang has been correspondingly successful.

In the province of An-hwei the geological conditions are similar to those in Kiang-su and Hu-pei. When the concession of the London & China Syndicate, in this province, was about to be abrogated in 1909, it was claimed by the concessionaires that they had proved the existence of iron ore worth over four million dollars, but I have been unable to secure any further exact data regarding this area. For a description of all the areas in China in which iron ores are known to occur, reference should be made to the original paper; those mentioned here are the districts which seem to offer the greatest promise of development by modern methods.

In conclusion, it may be said that, while our knowledge of the iron resources of the Chinese Empire is still inadequate, yet the general features appear to be these: Iron ores are widely distributed throughout the Empire, from north to south. In many places these have been the source of a more or less considerable native industry, which is steadily waning, because of the unsatisfactory quality of the product. Owing to the peculiar features of the native methods it is not to be supposed that modern industries will necessarily develop in the same localities; on the contrary, the one modern plant is utilizing ores not previously worked by natives, and this will not improbably be the policy of its successors. In this development of the iron and steel industry it is most probable that the Yangtze valley will have a leading place, as there seems good reason to believe that iron ores of satisfactory quality and in sufficient quantity occur along a considerable portion of its length, and it also possesses the great commercial advantage of easy and cheap transportation, and a situation in the commercial centre of the Empire. The extremely low cost of labor permits a low cost of production, making tariff for the protection of the industry entirely unnecessary. The low price of silver in recent years has operated to benefit China in a two-fold manner, both by stimulating export trade, and by discouraging imports. The resultant increase of wealth will give increased ability to meet the initial large expenditures necessary to develop modern plants. A large and increasing market is assured by the Imperial regulation that all materials required in the construction of railroads and other public works shall be purchased from the Chinese plants, so far as these are able to furnish them. As a result it is to be expected that the iron and steel industry in China will have a large and healthy growth.

Copper Deposits of the Burro Mountains

By Sidney Paige

*The Burro mountains lie near and southwest of Silver City, Grant county, New Mexico. Silver City is reached by a spur of the A. T. & S. F. railway, which connects with the main line at Deming, New Mexico, a town about 46 miles to the south. The Southern Pacific railroad likewise passes through Deming.

The Burro mountains consist of two distinct mountain masses, Big Burro and Little Burro, rising near the border of a semidesert region. The Big Burro mountain mass is subconical in form, and its flanks slope from a central peak, at an elevation of 8054 ft., at first steeply and then gently, to meet and finally merge with the desert deposits at its base. The chalcocite deposits of the Burro mountains lie at the foot and on the northeast side of the Big Burro mountains. Four companies were developing the field at the time of my visit—the Burro Mountain Copper Co., the Chemung Copper Co., the Savannah Copper Co., and the Mangas Development Company.

The first and salient fact connected with the occurrence of the chalcocite orebodies near Leopold and Tyrone is the intrusion of a mass of quartz monzonite of subcircular outcrop into a pre-Cambrian granitic complex, for the important chalcocite orebodies are connected with this intrusive rock. The pre-Cambrian complex comprises various types of coarse to medium grained granites and associated porphyry and pegmatitic dikes, with still later rhyolitic dike and stock-like intrusions. The quartz monzonite is a medium to coarse grained granular rock of rather light appearance when fresh. Both even granular and porphyritic phases are present, and dikes of nearly the same composition as the main mass are locally abundant. These dikes are later than the main mass and are characterized by very large phenocrysts of feldspar, some an inch or more in length. The quartz monzonite when coarsely granular is composed of quartz, oligoclase and orthoclase feldspar, and a subordinate amount of biotite and hornblende. The oligoclase crystals are fairly well formed, and many of them are partly inclosed in crystals of orthoclase and quartz. Sphene, apatite, magnetite, and a little chlorite are present. The porphyritic phases contain phenocrysts of oligoclase, with perhaps a little andesine and albite, and of biotite embedded in a fine mosaic of quartz and orthoclase with a little twinned feldspar. Quartz makes up about half of the groundmass. Apatite, sphene, and magnetite are accessory minerals. In both the even-grained and porphyritic phases of the quartz monzonite the biotite mica is noticeable in hand specimens, its lustrous black color contrasting strongly with the otherwise light appearance of the rock. In the ore-bearing zone, however, the monzonite takes on a quite different apearance; it is iron stained, fractured, and silicified; the biotite has generally disappeared: kaolinization of the feldspars is prominent, and hills in this zone have a characteristic rough, jagged, gossan-like appearance.

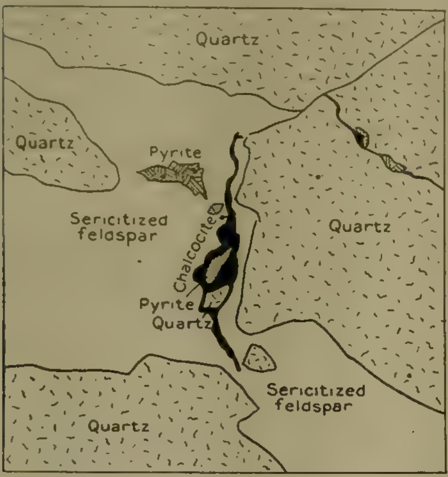

Fig. 1. VEINLET SHOWING NODULE OF PYRITE SURROUNDED BY CHALCOCITE.

The second important condition affecting the locus of the ore deposits is the intensity and distribution of the fracturing of the quartz monzonite. Where solid and unaltered this rock does not carry ore. Where intensely fractured it carries ore. There is a distinct and traceable gradation from the zone of intense fracture to the areas of essential solidity, and the surface exposure of the fractured mass has a comparatively definite form. It may be represented as a triangle pointing southwest, its point approximately 1½ miles southwest of Leopold and its base formed by a line passing from Tyrone to Oak Grove. The line of greatest fracture lies between Leopold and Tyrone and forms roughly the north side of the triangle. This north edge follows for a portion of the distance the contact between the quartz monzonite and the pre-Cambrian granites to the north, and present data seem to indicate that mineralization of this type is not extensive north of this contact. Southward from this zone of greatest fracture the rock gradually becomes more solid and less altered. A study of the mines shows clearly that the depth to which oxidation has penetrated the rocks increases in a northeasterly direction, from Leopold to Tyrone—and, further, that toward the south the dip and strike of the fractures shift. In the region about Tyrone the strongest fractures observed in the mines strike northeasterly and dip at different angles to the south. On the southern border of the fractured zone the dominant fractures strike east, with a northward dip, though here also many other fractures are found. Considering a number of these fissures as fault planes, it may readily be seen that a pyramid-shaped block is involved in the ore-bearing

---

*Abstract from 'Contributions to Economic Geology, 1910,' U. S. Geol. Surv., Bull. 470-C.

zone and that while the limiting fractures of this block (those near the northern and southern edges) will meet at the surface near the point of the pyramid, they will meet at increasing depths as distance from the point is gained. It would be expected that percolating water under the influence of such a system of breaks would tend to migrate down the planes of the breaks and would move toward the zone of most intense fracture.

The present conditions of the orebodies, so far as mineralization is concerned, may be attributed to three processes—primary mineralization, enrichment, and leaching.

Primary mineralization consisted in the deposition of cupriferous iron pyrite (probably finely intergrown chalcopyrite with pyrite) and locally quartz. The introduction of the pyrite followed the fracturing of the quartz monzonite. The solutions which carried the sulphides not only deposited their burden in the innumerable fractures but likewise soaked into the body of the rock. Deposition was greatest along lines of easiest passage, that is, in well defined fissures. At the close of the period of deposition of the primary ore the mass of the rock consisted of a network of veins and veinlets of iron pyrite, with locally quartz and a little chalcopyrite. The feldspar of the rock was much altered to sericite and the ferromagnesian minerals were chloritized.

The formation of orebodies from this stockwork of pyrite veins was clearly a result of secondary enrichment. An opportunity for such enrichment was afforded before and during the Quaternary cycle of erosion, in which were laid down those widespread deposits of gravels and sands which now fill the Mangas valley and the country east and south. The process of enrichment is well known, and consists first in the oxidation of the unaltered pyrite near the surface by surficial waters, and second, in the deposition of chalcocite at lower levels by downward-percolating water, which in the main carried copper in a sulphate solution. The junction of several fissure systems and the local damming of percolating waters against relatively impervious dikes have tended to produce enrichment. A microscopic examination of a number of thin sections cut from sulphide-bearing rocks in the mine of the Chemung Copper Co. shows rather plainly certain of the stages in the formation of the chalcocite. Fig. 1 shows a veinlet cutting feldspar in which a nodule of pyrite is surrounded by chalcocite; a little quartz is present. Near this veinlet may be seen grains of unaltered sulphides. In other specimens the rock is speckled with grains of unaltered pyrite, near which are chalcocite grains, some without any signs of the original pyrite and some showing replacement.

It is a characteristic of this district that much of the ore-bearing territory has been thoroughly leached. Portions of strong veins of chalcocite are locally leached, nothing remaining of the original mineralization except a network of limonite veins. The disseminated stockworks also are locally so impoverished as to preclude their extraction at the present price of copper. This process of late leaching is well shown in some places where vertical fractures cut across eastward-dipping veins.

The thickness of the blanket of barren ground overlying the orebodies is extremely variable. In the country southeast of Leopold it varies from a few feet to 500 feet. Near Leopold there is reason to believe that the topography of the surface affects the upper limit of the ore. For example, an orebody at a certain level will pass horizontally into leached ground, as a gulch on the surface is approached—that is, locally leaching is at lower levels directly beneath stream channels. Near strong veins and faults, too, leaching is deeper than in the adjacent ground. The thickness of the chalcocite zone also is variable. Southeast of Leopold unaltered sulphides are found locally at a depth of 380 ft., above which is 180 ft. of secondarily enriched ground. The leached ground therefore is 200 ft. deep. Again, a drill found unaltered sulphides at 250 ft., and at another locality unaltered sulphides appear at 300 ft. The ground carrying chalcocite is locally 200 to 300 ft. thick. In the Tyrone country leaching is locally very deep, 700 ft. or more.

Permanent water-level also is variable, standing 300 to 500 ft. beneath the surface. It may vary as much as 200 ft. in half a mile. The amount of water increases rapidly as the foot-wall fault near Tyrone is approached, indicating increased flowage near such breaks and accounting for the deeper leaching adjacent to them.

Broadly considered, the orebodies that have been best developed fall into two classes—those which are directly connected with veins and those which are not. Of the former several have been worked extensively in the territory southeast of Leopold, and much rich ore was extracted. In the mines near Leopold and Tyrone, also, much rich ore has been extracted from veins. The second class includes cigar-shaped masses of chalcocite ore and irregularly shaped blocks of ground grading off at the edges into rock too poor to be commercial. This grading off into lean material is in some places due to a change to unaltered sulphides, in others to a change to leached material. A number of these orebodies are several hundred feet in length, breadth, and thickness.

The material considered ore in these mines varies in copper content from 2.5 to 3%. As a rule the costs of mining and price of copper will determine when an orebody will cease to be profitable to work. At the time of my visit development by the Savannah Copper Co. was confined to drilling. A number of mines now closed, but worked in the past, are controlled by this company, but it was not practicable to study the underground workings. The more important shafts are shown in Fig. 2. The Mangas Development Co. also confined its operations to drilling. Active development by driving and shaft-sinking was under way only on the property of the Burro Mountain Copper Co. and the Chemung Copper Company.

Cupferron

Under the name 'Cupferron,' Oskar Baudisch has introduced the ammonium salt of nitrosophenyl-hydroxylamine, $C_6H_5(NO)ONH_4$, into quantitative analysis as a precipitant for cupric and ferric ions. By means of cupferron, iron and copper may be separated very rapidly and exactly, not only from one another, but also from almost all the other metals. The new method exceeds in elegance, simplicity, and rapidity of operation all the methods previously known for the separation of iron and copper, and has already met with great favor in technical chemical analysis in factories and mining and metallurgical plants. The advantages of precipitating with cupferron, as given in a recent number of *The Journal of Industrial and Engineering Chemistry*, are: (1) Iron and copper are precipitated from solutions strongly acid either with mineral or acetic acids. The precipitated iron and copper salts may be easily and thoroughly washed free from the chlorides, nitrates, and sulphates of any other metals which may be in solution. (2) The precipitate settles rapidly and may be filtered off without loss of time. (3) The separation of the iron from the copper is accomplished simply by washing the precipitate on the filter with dilute ammonium hydroxide solution. The ferric salt is completely insoluble and remains on the filter. (4) The iron salt is readily soluble in ether, chloroform, and acetone, and may be dissolved, on the filter, away from any other metallic salts such as Pb, Ag, Hg, Sn salts, which may have been simultaneously precipitated. The particular value of the new method lies in the fact that by its means iron may be rapidly separated from aluminum, manganese, chromium, nickel, and cobalt. The 'cupferron' method has been thoroughly tested from many sides. Cupferron will undoubtedly find extensive application in the quantitative analysis of widely different materials, for it has also been discovered that titanium, cerium, and zirconium may be quantitatively precipitated from acid solutions by it.

THE Santa Maria oilfield furnishes the greatest amount of natural gas in California. There are no dry wells, and gas is separated from the oil in gas traps. About 70% of the total production is used for industrial purposes.

Arizona Metal Production in 1910

The total value of the mine output of gold, silver, copper, lead, and zinc in Arizona in 1910, according to V. C. Heikes, of the United States Geological Survey, was $42,731,519, against $44,053,023 in 1909. The decrease in value in Arizona, as in California, was due mainly to the decrease in the production of copper.

The total production of gold in Arizona in 1910 was 152,350.58 oz., valued at $3,149,366, an increase in value of $411,866. Of this output, 1257.27 oz. came from placers, 95,395.07 oz. from silicious ore, and 52,707.40 oz. from copper ore. From bullion in gold and silver mills were recovered 84,173.85 oz., concentrate produced 9955.76 oz., and crude ore sent to smelters contained 56,443.59 oz. The largest production of gold was from Mohave county $1,145,022 in 1910, against $356,363 in 1909.

Arizona's silver production in 1910 was 2,566,528 oz., valued at $1,385,925, against 2,601,161 oz., valued at $1,352,604, in 1909. Of this output 1,934,363 oz. came from copper ore, 440,126 oz. from silicious ore, and 119,034 oz. from lead ore. Bullion at gold and silver mills produced 59,812 oz. of silver in 1910, concentrate produced 96,894 oz., and crude ore sent to smelters contained 2,402,229 oz. Cochise county produced 1,208,274 oz. of silver in 1910, against 1,454,390 oz. in 1909, and Yavapai county, 699,702 oz. in 1910, against 578,580 oz. in 1909.

Copper production decreased in Arizona from 303,899,461 lb., valued at $39,506,930, in 1909, to 297,491,151 lb., valued at $37,781,376, in 1910, but Arizona still ranked first among the copper-producing States in the country in 1910. Concentrate produced 59,425,058 lb. of the output and crude ore sent to smelters produced 237,774,349 lb. Cochise county, which includes the great Warren or Bisbee district, produced 145,310,623 lb. of copper, against 140,810,472 lb. in 1909. Greenlee county, embracing the former eastern portion of Graham county and including the famous Clifton-Morenci copper region of Copper mountain and Greenlee districts, produced 72,878,094 lb. of copper, against 71,825,750 lb. in 1909. Yavapai county, incluring the Verde district, produced 40,824,556 lb. of copper, against 37,125,964 lb. in 1909, and Gila county, including the Globe district, produced 31,330,222 lb. of copper in 1910, against 39,451,896 lb. in 1909.

The production of lead in Arizona in 1910 was 2,696,998 lb., valued at $118,668, against 3,098,083 lb., valued at $133,218, in 1909. Cochise county, in which are the Tombstone mines, produced 1,176,416 lb., followed by Mohave county, with 740,091 lb. Increased output in 1910 was made from Mohave and Santa Cruz counties. Concentrate produced 300,268 lb. of lead in Arizona in 1910 and 2,393,610 lb. was contained in crude ore sent to smelters.

The zinc production of Arizona was 5,484,899 lb., valued at $296,184, in 1910, against 5,977,237 lb., valued at $322,771, in 1909. Mohave county, mainly from Union Pass camp, produced 5,474,046 lb. of zinc in 1910, against 5,264,121 lb. in 1909. Cochise county, which produced 713,116 lb. of zinc in 1909 from the Tombstone district, produced none in 1909.

There were 373 mines producing gold, silver, copper, lead, or zinc in Arizona in 1910, against 268 in 1909.

The total quantity of ore sold or treated in Arizona in 1910 was 3,914,969 short tons, a decrease of 111,986 tons.

Mine Production of Gold, Silver, Copper, Lead, and Zinc in Arizona in 1910 by Counties.

[By Victor C. Heikes, U. S. Geological Survey.]

Counties.	Ore treated, Tons.	Gold.*	Silver,* Fine ounces.	Copper, Pounds.	Lead, Pounds.	Zinc, Pounds.	Total value.
Cochise	1,294,282	$587,476	1,208,274	145,310,623	1,176,416	....	$19,746,155

*Includes placer production.

Galvanizing Steel in Zinc Dust

By Alfred Sang

*The instantaneous galvanizing of steel in zinc dust above 420 C. is readily explained by completing the theory which I developed as far back as 1907. I will now state it in its complete form. Zinc dust is produced by the sudden cooling of the vapor of zinc, and the transition from the gaseous to the solid state is so rapid that, for all practical purposes, the liquid state is skipped. The setting of the zinc, brought about by sudden chilling, prevents regular arrangement of the molecules along determined stereochemical lines; it forbids the formation of crystals, for which time is required. The heat of solution of matter in an amorphous state is always higher than when in a crystalline state; the same is true of a strained condition, which likewise presents an amorphous appearance. At the time of formation, considerable heat is retained which would have been radiated by slow cooling. The condition is one of physical instability resulting in readier and, oftentimes, explosive decomposition.

The physical instability of zinc dust may be explained thus: in the prolongs of zinc furnaces the uncondensed vapor is suddenly chilled and collects in minute drops which are instantly congealed at the surface and oxidized, forming a rigid spherical skin or crust. Within this crust the liquid zinc cools and contracts more slowly, but the rigidity of the crust does not permit the drawing in of the surface to form the facets of a crystal and compensate this internal contraction. Thus, voids must exist within the crust and we may presume a structure which might be described as 'piped radially' or as negatively crystalline. Below the melting point of zinc this condition persists, but affinities and thermal inducements find a readier response from zinc dust than from any other form of zinc, both by reason of the enormous amounts of free surface and because of this unstable condition. At about 415°, which is the melting point of zinc, the strain within the zinc dust particles is totally or almost totally relieved, as indicated by the loss of heat, although some of the latent heat must be retained for fusion.

At high temperatures zinc dust is pasty, because formed of innumerable little bags of melted zinc, but these will not coalesce on account of their small size and closely packed condition, unless considerable pressure is used. These minute bladders might be compared to soft-shell turtle's eggs; they form a plastic and cellular mass. If, however, a reducing agent, say a drop of coal tar, is introduced, reduction of the skin takes place and we get a small mass of more or less spongy metallic zinc. If a metal which is electro-negative to zinc, such as iron, is put into contact with these bags of zinc, reduction and an exchange of metals take place, the bag is punctured at the point of contact, and the zinc spreads itself on the iron. Hence it is that steel can be galvanized in this manner by means of a plant closely resembling a hot galvanizing plant, for the process is, in fact, one of hot galvanizing.

---

*Excerpt from a paper presented before the American Electrochemical Society, Toronto, September 21 to 23.

Sluices

At the LaGrange mine, near Weaverville in Trinity county, California, the sluice-boxes have a grade of 8 inches in 12 ft. and sand and gravel travel in them at the rate of 27 ft. per second; boulders weighing from 300 to 600 lb. each, 20 ft. per second; boulders weighing 600 to 2000 lb., 16 to 17 ft. per second; boulders weighing 2000 to 5000 lb., 13 ft. per second; boulders weighing 5000 lb. upward, 6 ft. per second. The ratio of water to solids by volume is 9 to 1, or, in other words, water will carry 10% of solid matter. On ordinary sand and gravel a velocity of not less than 10 ft. per second of water is required to move solid material, and it may be seen from the actual data given above that a much higher velocity is required where the gravel carries large boulders. Without knowing the dimensions of the LaGrange flume, the velocity of the water in the specific case mentioned above cannot be calculated, but the formula as ordinarily used for this purpose is as follows:

P = Length of wetted perimeter in feet.

T = Top width in feet of surface of water.

B = Bottom width in feet of ditch.

D = Depth in feet from surface of water to bottom.

C = Constant which varies from 30 to 100.

H = Height in feet of difference of level of the section under consideration.

A = Cross-section area of waterway in square feet.

V = Mean velocity of flow in feet per second.

Q = Flow in cubic feet per minute.

L = Horizontal length in feet of section of ditch under consideration.

$$V = C\sqrt{\frac{A}{P} \cdot \frac{H}{L}}$$

$$Q = VA \times 60$$

The constant, C, is ordinarily taken as 32 for trapezoidal earth ditches, 100 for trapezoidal flumes built of planed wood or sheet steel, and 90 for rectangular flumes of unplaned plank. For ditches in clay, etc., with good smooth sides an approximate estimate should be made in which the constant would lie somewhere between that for trapezoidal earth ditches and for planed wood flumes.

Where the topography is such that any gradient desired can be secured, the grade adopted will depend upon the character of the gravel to be moved; with 2 inches in 12 ft. as a minimum, and 12 inches in 12 ft. as a maximum. Where the gravel is coarse, or cemented, or there is much clay, steeper gradients are necessary. But even when light gravel is being washed it is better to use a grade of at least 6 inches in 12 ft., as more material can be washed and the labor of handling large rocks is much decreased. In washing heavy gravel the water should be deep enough to cover the largest boulders sent down, while for light gravel the water only needs to have enough force to carry the rocks through the sluice without allowing the packing of black sand. The packing of the black sand is worse when too much water is used, and the best results are obtained with shallow streams on as light a grade as is consonant with a reasonable rate of working and a not excessive amount of labor for removing rocks from the sluice.

Placer Gold in Northwestern Montana

Many glacial moraines contain particles of gold, yet the metal is rarely so abundant as to make their treatment profitable. This is due to the fact that running water has not had opportunity to concentrate the precious metal scoured by the glacier from the decomposed surface of the mountains. In a short report, however, just issued by the United States Geological Survey, F. C. Schrader gives an interesting account of gold-bearing ground moraines at Kennedy creek and Libby creek, Montana. The Kennedy creek deposit, says Mr. Schrader, is commonly known to mining men who have examined it as ancient lake gravel, but it seems plainly to be a subglacial or ice-laid deposit of till—a ground moraine. The material is evidently derived from the upland mountains on the northeast, whence it was scoured off the surface by the ice-sheet, shoved and dragged down the slopes, crushed, ground, and finally compressed beneath the ponderous ice mass. The ice sheet probably covered the basin with a thickness of a thousand or more feet for a period of centuries.

A most unusual feature is the fact that this glacial deposit does not seem to have been concentrated by later streams nor to have derived its gold from pre-existing placers. If this view is correct there must occur in the mountains or uplands to the northeast, in the path of the ice that deposited the moraine, some rich gold-bearing vein or bedrock area as yet undiscovered.

Tests made of the deposit in six different shafts fairly well distributed over about half a square mile in the southern part of the basin show the gold content of the deposits to range from 20c. per cubic yard near the surface to about $5 per cubic yard in the bottom foot of gravel next to bedrock, from which it is readily apparent that the deposits contain considerable gold. By some mining men the amount of gold present in the basin has been estimated at $18,000,000. From the data obtained in the present tests, after reasonable allowance is made for boulders, which in the lower part of the section constitute about 10% of the material, the deposit in the southern part of the basin seems to contain on the average about 80c. per cubic yard, including everything from the surface down to bedrock, or about $4 per bedrock yard. This would amount to about $17,360 per acre, or more than $5,500,000 for the Kennedy placer portion of the area examined. The estimate does not include the neck of the deposit in the downstream outlet, which in places attains a thickness of 80 ft. or more and is known to carry considerable gold. In the basin as a whole, if gravel of this grade is present throughout, there is probably more than $11,000,000 worth of gold.

The entire district of which Kennedy creek is a portion is roughly estimated by Mr. Schrader to contain about $100,000,000 worth of gold, much of which, he states, to judge from the attention the district is receiving, will probably be won in the near future. A copy of Mr. Schrader's report, which is contained in Bulletin 470-B, may be obtained on application to the Director, United States Geological Survey, Washington, District of Columbia.

Increased Use of Oil on Railroads

An interesting feature shown in the report on petroleum for 1910, by the United States Geological Survey, now in preparation, is the statement of the extent to which oil enters into railroad transportation. The total length of railroad line operated by the use of fuel oil in 1910 was 21,075 miles, a trackage equivalent to that of practically five transcontinental lines stretching across the United States from ocean to ocean. Some of the lines that use oil, however, also use coal. The number of barrels of fuel oil (of 42 gal. each) consumed by the railroads of the country in 1910 is stated to have been 24,526,883. This includes 768,762 bbl. used by the railroads as fuel otherwise than in locomotives. The total number of miles run by oil-burning engines in 1910 was 88,318,947.

Discussion

Readers of the Mining and Scientific Press are invited to use this department for the discussion of technical and other matters pertaining to mining and metallurgy. The Editor welcomes the expression of views contrary to his own, believing that careful criticism is more valuable than casual compliment. Insertion of any contribution is determined by its probable interest to the readers of this journal.

Cyaniding Base Silver Ores

The Editor:

Sir—In reading over articles on fine grinding as they appear in the various mining journals, as well as enthusiastic metallurgical reports by firms supplying mining machinery, one may in time become convinced that all-sliming must, in some mysterious way, prove a solution of the treatment problem, even for the most basic and refractory ores. One feature, however, that is not always given the prominence which its importance demands, is that the finer the pulp is ground the more readily will it give up its undesirable base minerals as well as the precious metals.

A very base partly oxidized silver ore with which I recently had to deal, in Mexico, gave rise to some interesting results when I came to examine the working solutions after a month's run. The ore contained traces of copper and manganese, some zinc and antimony, considerable amounts of arsenic as mispickel, calcium and magnesium as carbonates, and alumina and silica; also large quantities of iron, both as sulphide and oxide, with occasional small amounts of ferrous iron as ferrous sulphate.

In assaying the solutions by the addition of lead acetate and throwing down the silver in a lead sponge by means of zinc shavings, I found it necessary to filter and scorify before cupelling. A heavy white precipitate which formed on introducing a solution of lead acetate precipitated a portion of the silver from solution, and the white precipitate could not be satisfactorily collected with the lead sponge. 4 A.T. of working solution containing 18.3 mg. of silver to which were added 10 c.c. of a 10% lead acetate solution, yielded 3 gm. of white precipitate containing 0.3 mg. of silver. Hence, 1.60% of the silver was thrown out of solution by the white precipitate under the above conditions. I later found this white precipitate to be soluble in ammonium acetate, which would indicate a lead salt, so that it was possible to shorten the work somewhat by collecting the sponge and cupelling direct, though not advisable. Other results obtained were: total sulphur, 0.11%; sulphocyanides and nitrites, 0.18%; soluble sulphides, trace; copper, 0.09%. The remedy usually recommended for copper is the use of a zinc-lead couple in the zinc-boxes.

Tests with mercuric chloride gave unusual results. The addition of sufficient $HgCl_2$ to destroy all free cyanide in 4 A.T. of the working solution, containing 18.3 mg. of silver, yielded a precipitate weighing 4.5 gm. and containing 18.2 mg. of silver, thus indicating that the precipitation of the silver had been practically complete. In a second test a precipitate weighing 0.5 gm. contained silver amounting to 2.03 mg., which would indicate that the silver thrown out of solution was approximately proportional to the amount of the yellow precipitate found. Examination of this yellow precipitate showed that it was composed mainly of silky white mercurous chloride, occluded and masked by a yellow precipitate containing copper. The HgCl was reduced from the $HgCl_2$, due to the strong reducing action of the working solution. As HgCl is soluble in a KCN solution, why it should be formed and remain in suspension in this particular case is another interesting problem. Remedies which suggest themselves for this condition, are to remove the copper and to try to decrease the reducing power of the solution.

A test for reducing power of the working solution as compared with that of a newly made up solution was made by oxidizing each with a standard N/10 $KMnO_4$ solution. Ten cubic centimetres of the new solution (KCN 0.235%) required 0.1 c.c. of the standard $KMnO_4$ solution, while 10 c.c. of the working solution (free KCN 0.235%) required 11.6 c.c. of the standard $KMnO_4$ solution, which means a reducing power of 116 times that of the new solution. Inasmuch as it is now thoroughly established that gold and silver require oxygen for solution, and this high reducing power can hardly be taken otherwise than indicating an absence of oxygen and oxidizing agents, it would seem to be no discredit to the cyanide process that an extraction of 70 to 85% could be maintained under such conditions, even though a higher extraction had been hoped for from the results of the preliminary examination.

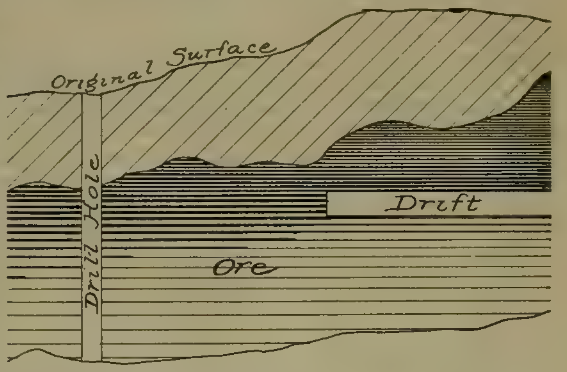
J. E. Clark.

Los Angeles, September 21.

Recent Problems In Copper Production

The Editor:

Sir—A few further points concerning some practical features may be of interest in supplementing your very interesting article on recent problems of copper production. In regard to exploration by churn-drills, which I believe more accurate and far less expensive than the use of drifts and raises, it should be noted that the holes are cased and the casing follows down, thus eliminating the possibility of salting, and giving a larger and more accurate sample than can be taken by cutting a vertical sample in a raise. As the ore is generally richest immediately under the capping, decreasing in grade as depth is attained, there will be less liability of error when all the samples representing a block of ore are taken from vertical sections. For example, assume the average condition as in the accompanying sketch, in which the heaviest shading represents the richest ore. It will be seen how important it is to take only vertical sections and not drift samples, which, running horizontally, only represent the grade at the elevation of the drift itself.



The fact that a steam-shovel is only engaged in useful work for 40% of the time may appear low, but it must be remembered that shovels often go out of commission, and the best plan is to give them sufficient motive power and cars to secure minimum costs. For this reason a shovel can be oversupplied as well as undersupplied with cars. That 1.75 to 1 is the most desirable slope for economical operation at the Nevada Consolidated is true while retaining the track benches for further stripping, but when the ore limits have been reached, the benches can be cut away and the final slope brought to about 42 to 45 degrees.

At the Steptoe Valley smelter the average throat draught of the reverberatory-furnaces with coal firing was 1.4 in water and at the stack 1.8 in. With oil the throat draught averages only 0.5 in., and stack about 1.6 in. The best boiler to employ for the recovery of heat from the furnace gases is the vertical tubular type. This allows some self-cleaning of tubes from flue-dust by gravity. In the management of converters it is found that basic linings cannot stand excessively high temperatures so well as acid linings, neither can they stand the same range of temperatures without serious deterioration. This is a very important point in the successful use of basic lining.

C. B. Lakenan.

Ely, Nevada, September 30.

NEW YORK

Spasmodic Condition of Market.—Dull Copper Outlook. — Development at Chino. — Calumet-Hecla Merger.—International Combination.—Kerr Lake Annual Report.—La Rose Surplus.

Not since the days of 1907 has there been such market history made as that recorded on the tape during the past ten days. It is a patent example of the irony of market action that the Standard Oil Co., long held up to view as the most iniquitous of monopolized combinations, could be dissolved by decree of the United States Supreme Court without suffering unduly in market price, while the United States Steel Corporation, the greatest of J. P. Morgan's achievements, the chief monument of his constructive genius, pointed to as a beneficent example of the modern-day triumph of coöperation over the old principle of competition, should lead in a market smash of terrific proportions when the rumor of impending prosecution began to look as if there were some measure of truth behind it. For two weeks Steel has been under heavy pressure. The press has demanded some expression as to intended prosecution from the Attorney General of the United States, as to dissolution or rumored reorganization from the various heads of the steel corporation, but such fragmentary utterances as have been forthcoming have by no means cleared the atmosphere. Early in the current week, J. P. Morgan made his first public move since his recent return from Europe, when in conjunction with E. H. Gary, he issued a statement to the effect that the Steel trust has always been careful to keep within the limits of the Sherman Anti-Trust Act and that there was no intention of dissolution or reorganization. A sharp rally, the first for several long strenuous days, followed, only to be swept aside by a renewed flood tide of liquidation. The volume of trading has on some of the recent days been larger than any time since 1907. New York as a market centre is feeling the strain of the situation both at home and abroad. Germany and France on the verge of a conflict that is now said to have been much more narrowly averted than was shown by general report, England's universal sympathetic strike development, riots in Vienna, and war between Italy and Turkey indicate that in some form, unrest is everywhere.

The mining industry is more affected by the influences controlling the copper metal market than in any other way. The European markets have been consuming copper in record-breaking quantities. Now the most optimistic are forced to anticipate a lessened demand from abroad. Quick improvement at home is out of the question, and as there are some mines that must 'willy nilly' produce at capacity, the higher cost coppers are facing a most unenviable situation. The recent changes in the United Metals Selling Co. left that concern where it is no longer maintaining prices as it once did. It can only be said therefore that although technically the position of copper is all that could be asked, accumulated stocks on this side equaling only thirty days output and the world's visible supply as estimated, equivalent to but three months production (certainly not more than a safe margin under normal conditions), yet there is nothing to be seen in the future, at least for some months, but lower prices and an increasing surplus. There are some copper mines that can view the outlook with equanimity. Utah Copper's recent breaking of all records for one month's output, Nevada Consolidated's preparation for winter work by stripping as far ahead as possible, the rushing of work on the newer properties, Ray, Chino, Miami, Braden, Inspiration, Mason Valley, and others, can mean but one thing. There is at hand a period when those mines that cannot produce copper for less than 10c. will be forced to suspend until increased constructive activity so augments the demand as to push prices up and as such demand rises and falls so will production from the higher-cost properties be regulated. In this class are such mines as the Granby, the Imperial, the Shattuck-Arizona, the Ballaklava, many Michigan mines, and others less important.

The Guggenheim string is growing in importance. Chino is to be a steam-shovel mine; its potential production is figured at 55,000,000 lb. per annum, with a cost of not above 8c. The concentrator of which the first 1000-ton unit goes into commission this month, is to be of 5000 ton daily capacity. The concentrate presumably will go to the American Smelting & Refining plant at Hayden, Arizona, which was originally planned and erection begun as the independent smelter of the Ray Consolidated Copper Co. The latter mine is now looked upon as second in importance to Utah Copper only, being capable of producing 100,000,000 lb. of copper per annum at a cost of 8½c. per pound. The estimated expenditure is $8,000,000. The market situation of each of these two immense enterprises is strikingly and consistently inconsistent. Months ago, each sold at nearly twice present market prices. The future of each was then undemonstrated. In the interim, money has been poured into each in vast quantity. The life of each has been made certain for a long time with long extensions more than possible. Yet, today both are regarded without great enthusiasm even by that part of the public which invests in mining issues and proclaims itself as looking for bargains. The attitude of the public is past understanding.

The Boston copper share market is suffering from the snarl occasioned by the Calumet-Hecla merger. It seems impossible to learn the real attitude of the sponsors for the consolidation. Stories to the effect that the whole matter would be dropped if it could be done without loss of dignity or prestige, are followed by defiances and announcements of determination to fight all the various suits through every possible tribunal until disposed of. Under prevailing conditions, it would seem that any talk of a copper merger could hardly be received seriously. Yet, the tour of W. E. Corey, John D. Ryan, L. D. Ricketts, and W. D. Thornton, of the Greene-Cananea, R. L. Agassiz, vice-president of the Calumet & Hecla, and some other associates, is said to mean a coming coalition of the important producers. To avoid a clash with Federal authorities, it is said the parent organization will be formed in England and headed by Baron Rothschild. While such a solution of the copper situation seems at first somewhat improbable, yet it must be admitted that the formation of a merger within the jurisdiction of the United States is out of the question, while the need of an organization to correct conditions is as universally recognized. If the legal minds, which have been unable so far to plan a copper merger that would not be born an outlaw, have at length devised some way of seeking cover abroad while retaining control of property in this country, England may prepare headquarters, not only for the yet unborn copper trust, but for numberless other hard-pressed corporations that are ready to seek sanctuary and that would welcome an opportunity to elude the Attorney General.

The Kerr Lake annual report was given out this week, showing a production of 2,388,420 oz., as compared with 3,046,295 oz. for the year preceding. The cost of production was 14.69c. per oz., as compared with 13.27c. per oz. for the year 1910. The report shows that Kerr Lake owns some 150,000 shares of Wettlaufer. Perhaps the item in which shareholders are most vitally interested is that of the ore reserves and the future life of the mine. On this point the mine manager says, "on account of the great irregularity in the ore deposits, your manager does not feel warranted in making an estimate, either of the total ore in sight in the mine, or of the value of the probable ore," which is, to say the least, somewhat indefinite. It is greatly to be deplored that the Cobalt deposits lend themselves so little to adequate measurement. The camp has produced so much from so small an outlay that its record will stand a long time, as a poor man's camp, but the public has shied at the element of uncertain length of life; and dividends and share prices have for months held no proper proportions. The La Rose directors are expected to meet within two or three weeks and to take some action in distributing the $1,400,000 surplus which has accumulated since the dividend rate was cut down to 8% per annum.

GOLDFIELD, NEVADA

Deep Prospecting at Goldfield.—Development of Diamondfield Black Butte.—Work on the Vernal.—Reorganization of Silver Pick.—Notes of District.

At the annual stockholders' meeting of the Goldfield Merger Mines Co., held at Seattle last week, J. Ross Clark, brother of William A. Clark, C. O. Whittemore, vice-president and general counsel for the Clark railroads, C. E. Redman, an officer of the roads, John Erikson, and George A. Kernick were elected directors, and the purchase of all property and assets of the Goldfield St. Ives Mining Co., one of the components of the Merger company, for $530,000, or on a basis of practically 35c. per share, was authorized. The directors will meet in Goldfield on October 5, when officers will be chosen for the ensuing year and announcement will be made of plans for the development of the Merger Mines ground, including the sinking of a 2000-ft. 4-compartment shaft at once, according to official statements. It is now regarded as probable that the directors will decide to enlarge and deepen the old company shaft on the Moonshine claim, already over 600 ft. deep.

Details of a deal that will involve the extensive development of the Diamondfield Black Butte mine will be announced soon. Three leases are producing ore of good grade from shallow workings about the butte and another lessee will operate on the 300-ft. level from the main shaft. It is said that the impending deal will mean either the merging of the Black Butte with the adjoining Goldfield Belmont, and possibly another property, or the passing of control of the Black Butte to the men who head the Goldfield Belmont and who are large stockholders in Tonopah-Belmont. The Black Butte has produced over $600,000 in ore of shipping grade, all from above the 300-ft. level, and has a large tonnage of milling ore exposed; enough to justify the erection of a mill of considerable capacity. A new ore-shoot, yielding $300 ore from 18 in. to 2 ft. wide, has lately been exposed in driving from one of the old adits.

Work is now in progress on the Vernal, adjoining the Belmont on the north and having the same vein from which the latter is extracting shipping ore on its 300-ft. level. Control of the Vernal has been acquired by J. A. Steinmetz, J. A. Vincent, and J. A. Janney, of Philadelphia. The work has been started from an old shaft on the Belmont, near the boundary, and driving is in progress at a depth of 112 ft., where seams of good ore are still exposed in the old drifts. A working shaft will be sunk as soon as the dip of the ore is determined.

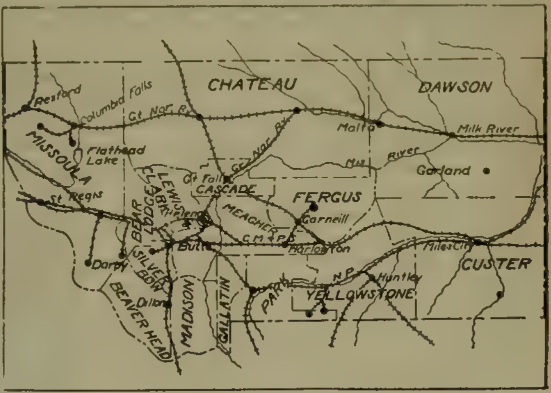
Another deep shaft and extended exploration will be started soon on the Silver Pick. This company has been reorganized on the assessable stock basis, with Herman Zadig, of San Francisco, at its head. The claims adjoin the Mohawk and Combination mines of the Consolidated. Seams of high-grade ore have been exposed recently by lessees working in the old company shaft of the Daisy. Other lessees, working on the west end of the Daisy and east end of the Great Bend, are shipping good ore to the Nevada Goldfield mill. It is said that work will be started on a good scale before long on the property of the Goldfield Five-to-One Mines Co., which owns 13 claims near the Yellow Tiger, which has a main vein from 60 to 80 ft. wide and a large cross-vein intersecting the north vein. Work will also be resumed during the fall on the Nancy Donaldson group, which has produced small quantities of extremely rich ore. Reports of damage caused by the caving of a stope in the Florence mine are said to be unfounded, as many of the old stopes on upper levels have been backfilled and abandoned and their caving can cause no damage. The Florence mill continues to treat 170 tons per day, with excellent extraction and economy of operation. The Jumbo Extension is driving south on the 1030-ft. level and has some fairly good milling ore in workings on the 800 and 850-ft. levels, some of which was recently shipped to the sampler as a test. The Polverde claim of this company can now be regarded as permanently immune from the possibility of apex trouble with the Consolidated or any other adjoining properties.

BUTTE, MONTANA

Zinc Smelter at Butte.—Fire in the Neversweat.—Lowered Costs at Anaconda.—Soft Ground in the Ophir.—East Butte Production.—Good Ore in Little Annie.

It is reported that W. S. Clark will erect a large zinc smelter somewhere near Butte early next spring. The zinc mine Mr. Clark is now working in Butte is proving a profitable investment, and last year for the 12 months ended May 1, 1911, produced some 90,000 tons of high-grade ore which was treated at the concentrator of the Butte Reduction Works, leased from the Anaconda Copper Mining Company.

The Anaconda Copper Mining Co. is experiencing some difficulty with the fire which has been burning for years in the Neversweat and Anaconda mines. Only a short time ago some men were overcome by escaping gases through slight holes or leaks in the bulkheads of the Neversweat, and now the company is making preparations to effectually wall in the fire zone and forever prevent any further danger from escaping gas. Plans are being prepared and work will soon be started to build immense cement walls from the 1800 to the 1300-ft. level and thus completely close in the fire. It is estimated that the work will require six months, and this means the practical closing down of the mine for that time, but the shut-down will not mean that any less men will be employed or less ore hoisted, as the miners will be distributed among the other properties and the output increased accordingly.



MONTANA.

The closing up of several shafts, except for ventilation purposes, and the extensive use of electricity is bringing the costs of production to a point where the Anaconda company can easily earn its dividends and add something to the treasury surplus besides. Just now the company is undoubtedly putting copper down in New York at around 9c. per lb., and should reach 8c. per lb. by the end of the year.

At the Ophir mine of the Butte Central Copper Co. there is difficulty in finding solid ground for a station at the 1000-ft. level. The company is continuing its shipments of about 50 tons per week. All the ore is being taken from the 300-ft. level, where the rich find was made some months ago. The East Butte company will produce about 1,000,000 lb. of copper per month from now until the first of the year, and after the first of January, if conditions warrant, the production will be increased to about 1,225,000 lb., as the smelter can easily handle that amount. The only custom ores being received at the smelter come from the Butte & Ballaklava, the Butte-Alex Scott, and the Keating, the last gold ore. The Little Annie of the Butte-Alex Scott is developing into a valuable silver property. Although only down 200 ft., some ore is being taken out which averages 25 oz. in silver and about $1.50 in gold. The 200-ft. level is proving so rich that it has been decided to abandon for the time being the sinking of the shaft another 100 ft. and devote all energy to further developing the property on that level.

JOPLIN, MISSOURI

Prices and Production.—Bureau of Mines Investigation.—Importance of Proper Ventilation.—Steady Production from New Kansas District.—Zinc and Lead Notes.

Continued high prices for blende and calamine have resulted in the heavy surplus that had accumulated during the first part of the year being well cleaned up. In the bins of the district less than 4000 tons is available at present prices, that is, $42 to $45, basis of 60% for zincblende, and $23 to $25, basis of 40% for calamine. About 3000 tons, being held for $50 basis, is not considered a drug on the market. At the mines of the American Zinc, Lead & Smelting Co., at Prosperity, Mo., the blende reserves are in excess of 1200 tons, due to the inability of the American company to smelt its ore, strikes at the Kansas smelters having troubled that company for the past few months.

Among the new soft-ground mines that are figuring conspicuously in the weekly turn-ins is the Tilho, on the Scotia Mining Co.'s land, west of Joplin. The mine is within 1000 ft. of the famous old Scotia property, from which $300,000 worth of ore was produced, all treatment being on hand-jigs. Although the ore is found at shallow depths, 75 ft. being the extent of present development, and although the big pockets now being worked reach to within a few hundred feet of the outlying drifts of the old Scotia mine, operators who gouged the tract with drill-holes years ago, following the abandonment of the Scotia, failed to find the continuation of the run. Recent prospectors found the orebody by drilling, and the mine is now turning out about 120,000 tons of high-grade blende concentrate weekly.

Through inefficient milling methods, according to the belief of C. A. Wright, of the U. S. Bureau of Mines, who is now in the Joplin district, thousands of dollars worth of zincblende is lost annually. Mr. Wright has been detailed to spend eight or nine months investigating local conditions. That operators are appreciative of the efforts of the Bureau of Mines to improve local mining and milling conditions, if possible, is evidenced by the warm welcome received by Mr. Wright. The rehandling of tailing has become a factor of great importance throughout the district. Frequently the mill recovery from tailing is in excess of 2%. The Government is working on the theory that the saving of this ore in the first milling would eliminate the big expense of the rehandling. Mr. Wright lays great stress on the proper treatment of the finer ores. After thoroughly investigating conditions, he intends to make a detailed report on his findings.

Safety of its employees will be the first consideration of a new company that has taken over the Symmes mines on the Riseling estate west of Joplin. Development, in the past, has been along lines looking more toward a heavy production of concentrate than to proper handling of the ground. Ventilation in the ground has always been bad. J. B. Morsman and L. C. Sly, the new owners, intend to connect the north and south workings of the property as an initial step. Small side drifts are to be cut toward several drill-holes, through which pure air can flow into the workings. The company has remodeled the mill, and for the time being will handle ore from the upper level at a depth of 70 ft. The company has five shafts in ore, all connected by tramways with the mill. The capacity of the remodeled mill will be 300 tons per shift.

The pumping capacity has been doubled at the mines of the Eastern Lead & Zinc Co. at Lawton, Kan. The company, although working only shallow deposits at 40 to 70 ft., has since the floods been making several carloads of concentrate per week. The richer runs at 110 to 160 ft. are just being drained. This field was opened less than a year ago. A number of other companies are sinking shafts and conducting prospecting operations. Zincblende, lost to early-day operators, is being milled at the plant of the Harmon Mining Co. on the Prudential land, at Galena, Kan. The recovery is 4%. Pioneer miners cleaned their dirt on hand-jigs. Coarse boulders were discarded, as crushing devices at that time were inadequate to handle them. Thousands of tons of these old rock-heaps are to be re-worked. Development was carried down to the 100-ft. level, below which it was impossible to operate because of the heavy water. Pumping operations have now resulted in the water being lowered and a big stope is to be taken up. The water, heavily impregnated with sulphuric acid, has deleterious effects upon any metal; hence a wooden 2-stage centrifugal pump is employed. Gougers can find big profits in ground abandoned by larger companies. Several years ago the Lincoln Mining Co. constructed one of the largest plants in the sheet-ground district of Duenweg. It was operated for only a short time. Individual prospectors have now taken small leases on the tract, have gone into the old workings and from the small but rich seams of ore in roofs, walls, and ceilings, are producing weekly turn-ins which, to them, represent incomes far better than wages. Interest centres in new developments in the suburbs of Pierce City, Mo. This field has never been a producer of zinc. To the east mines have been opened at Aurora and Wentworth, and to the west are the Joplin and other well known camps. Henry Mulrein and associates are developing property owned by Fred Smith. Blende has been found in several prospect holes, and in the shaft, at the extremely shallow depth of 20 ft. Free ore is being sold in the rough for $8 and $10 per ton.

JOHANNESBURG, TRANSVAAL

Slump in East Rand Proprietary.—Over-sanguine Expectations.—Failure of Giesecke Mill.—Unfounded Claims.—Tin and Talk in Rhodesia.—Rhodesian Gold Mines.

A sensation has been created on the Rand through the shares of the East Rand Proprietary Mines, for some time the largest gold producer on the Rand, falling 25% during the last few months. It seems that it has been decided to reduce the dividend declaration for the year owing to, as stated in an official circular, the inability of the metallurgical plant to recover the usual percentage of gold sent to the mill. Dividends of 40% have been paid for some time, and according to R. R. Mabson, author of the 'Mines of South Africa,' there was every likelihood of the dividend being increased to 50%. This prognostication has, however, proved unjustified. As a matter of fact, the gold recovery of the East Rand Proprietary Mines has been causing some uneasiness for some time past, but the metallurgical difficulties indicated in the official circular issued to shareholders seem to be doubted as being the true cause in some quarters. The metallurgical talent in this department of the East Rand Proprietary is certainly quite as up to date as any other on the Rand, and it is feared that, after all, any falling off in the yield may be due to deeper causes than those given in the official explanation. It has been the practice on the East Rand Proprietary Mines to send to the mill a selected output such as would fairly represent the full average yield of the whole property and could be maintained as far as could be seen. Recently, however, certain sections of this huge property have not come up to expectations, and it may be that the strain thus thrown on the richer sections with the object of maintaining the average yield has been more than they could bear. That the deeper stopes have been entering poorer ground is also well known, as also the fact that a fairly large area of low-grade country is known to exist to the dip. As likewise there has been a modified change in the control of these mines, the new control may have deemed it necessary, or at all events advisable, under the circumstances, to reduce the dividend so as to prevent further disappointments. How long this reduced dividend may be paid is of course difficult to judge, but it shows how, even on extensive Rand properties with profits divided up to the hilt, unforeseen difficulties may arise and disturb what for years has been regarded as a fixed profit from what has hitherto been considered as almost a gilt edged security.

The Giesecke tube mill, as indicated in an earlier letter, has failed to come out of the Chamber of Mines trials with credit, and the Committee, in the face of the guarantees, have had no other alternative but to reject the machine after an expensive four months' trial at the Geldenhuis mine. It cannot be said that the Giesecke mill, despite the loud trumpeting with which its appearance on the Rand was announced, has done even as well as an ordinary ball mill, and its failure has been a keen disappointment to those who looked for a $\frac{2}{3}$ reduction in the capital costs of future Rand milling equipments. The truth appears to be that in its design and application the lessons taught by ordinary ball and tube milling equipment have been totally disregarded, with the results that the wear and tear, low efficiency, and high costs have proved stumbling blocks to its success. For some time to come the Californian stamp-mill will still hold the field on the Rand, and the recent mills employing stamps aided by tube-mills seem far more reliable and cheaper to work on the Rand than any of the substitutes yet introduced.

MANILA, P. I.

HEADWATERS MILL. — PROGRESS IN BENGUET DISTRICT. — START OF COLORADO MILL. — DREDGING THE GUMAUS RIVER.—COAL INDUSTRY DULL.—IRON DEPOSITS, AMBOS CAMARINES.

Actual mining operations in the Philippines have been at a low ebb during the past year. While there has been very little production, there has been considerable activity along the line of genuine exploration and development. All those who are interested in the mining industry in the Philippines have come to the conclusion that haste had better be made slowly. Of all the early ventures very little in the way of results can be shown. The chief events of the past year have been the beginning of operations of the Headwaters 10-stamp mill on the Antamok river in Benguet. This mill was erected by C. T. Durell of San Francisco. After the first successful clean-up Mr. Durell resigned, and is now about to leave for the United States, having turned over the mill to F. L. Cole, a Stanford man, who has had much experience in the Far East. The other properties in this district are fairly quiet. The Major Mining Co.'s mill is in operation. The stamps are dropping on the Benguet Consolidated, turning out a 100-oz. bar of bullion quite regularly. It will be recalled that in 1909 the cyanide plant in connection with this mill was destroyed in a typhoon. It is reported that this mill will very soon be rehabilitated.

PARACALE DREDGING GROUND, UPPER RIVER.

On the last boat going north a party of mining engineers from the Division of Mines went to Benguet to make an examination of about six properties at the request of some Hongkong capitalists. If this examination proves satisfactory these properties will be consolidated and a large mill erected on the Antamok or the Batwaan river. The recent injury to the Benguet road will probably cause some inconvenience for a time in the matter of getting in supplies and machinery to the mines. It is not yet known whether this road will be rebuilt, but at present the old Naguilin trail from San Fernando to Baguio is being put in shape. During the recent storm in the Beguet region the Weather Bureau reported a rainfall of 38 inches in 24 hours, which is probably the world's record. The mines in the district were uninjured by this storm. The proper location and construction of mills in this district, it will be readily seen, is a very serious matter and the exercise of foresight is necessary to prevent disasters.

In the Masbate district the 20-stamp mill on the Colorado properties will begin crushing about September 1. This mill is in charge of C. M. Eye, a graduate of the Colorado School of Mines, formerly of the Benguet Consolidated. There is very little else going on in the district, with the exception of more or less development work on various properties. A bar of gold was sent up a few days ago from the Mount Cogran mill in this district. In the Paracale Mambulao district practically all operations on the quartz properties have ceased for the time being, but in the adjacent property of Nalasvetan Mr. Boag has completed the installation of a Huntington mill, and a bar of gold has reached Manila from that property. The chief items of interest from this district are the successful floating of a company to place a Bucyrus dredge on the Gumaus river, a stream adjacent to the Paracale river. During the past three or four months some Australian capitalists have had engineers on the Paracale and Malaguit rivers, testing various properties, with a view to a consolidation. Among these is that on which the Paracale dredge has been so successful. The report of the Australian engineers is awaited with interest.

The coal industry of late has not prospered. The East Batan Coal Co. went into the hands of a receiver in May of this year, and William T. Nolting, special agent for the Governor-General, who has had marked success in handling various business enterprises in the Philippines, was appointed to act as manager and receiver for this company. He has the aid of E. Randolph Hix, an engineer from West Virginia, and it is believed that a severe setback to the coal industry will be averted by the timely stepping in of the Government. The United States Army mine has been indefinitely shut down.

The Mitsui Bussan Kaisha has recently had a Japanese mining engineer looking over an iron deposit on a small island in Mambulao bay, Ambos Camarines. A preliminary report on this property was also made by the Division of Mines some time ago. It is the opinion of all who have seen the deposit that there is a considerable amount of ore there and that it can be worked successfully. However, one bad feature is the export tax of $1 gold per ton on all ore shipped from the Philippine Islands. A petition has been presented to the Insular Collector of Customs of the Philippine Islands to have this tax removed, and he will make a recommendation in regard to this to the American Congress, but no immediate relief can be expected.

During the past year the Division of Mines Bureau of Science has had a party in the field about six months examining localities which might afford raw materials for cement manufacture, and a very promising area has been discovered on the island of Cebu. It is practically assured that one of the large New York firms having a branch office in Manila will consider the matter of erecting a plant there. Recently a prospector brought in some gem stones; garnets, ruby spinel, and emeralds, claiming to have discovered them on the island of Mindanao. They were examined by the Division of Mines and found to be very promising specimens. However, nothing definite is known about the locality.

General Mining News

ALASKA

Alaska Peninsula

L. L. Bales, a Seattle guide, is reported to have found extensive deposits of almost pure sulphur 200 miles from Unimak pass and about 45 miles from Sand Point. The deposit is 15 miles from the steamship route, but a good harbor has been found near by. Copper, iron, gold, coal, and oil discoveries have been reported on the peninsula in the past, but this is the first discovery of sulphur. A company is being organized in Seattle to develop the property.

Prince William Sound

A big rush has been started to Port Wells by a remarkably rich discovery made by Toolson & Stanton.

The Skyscraper group of claims adjoining the Valdez Bonanza M. Co.'s property, between Mineral creek and the glacier, has been bonded by C. G. Hubbard and B. Silverman.

With almost everything in place but the shafting, the new stamp-mill at Valdez will be ready to start this month, according to late reports.

Bornite has been discovered on Valdez creek by J. E. Smith, who recently returned to Valdez with about $3000 worth of gold dust.

Seward Peninsula

The *Northwestern*, the last steamer to leave Nome in October, will bring $1,000,000 in gold dust, according to advices from Seattle. It is estimated that 2000 persons will remain at Nome during the winter, as against 2600 last year.

The Tanana

A large placer deposit panning from $40 to $50 has been discovered on Hammond river, a tributary of the upper Koyukuk, according to despatches from Fairbanks. It is 116 ft. to bedrock there.

ARIZONA

Gila County

At a special meeting of the Superior & Boston Copper Co.'s stockholders, in the mine office at Globe, September 30, a vote was passed in favor of extending an offer of consolidation to the Arizona Commercial Copper Co. The vote was unanimous for the 157,512 shares represented. The McGaw 3-compartment shaft is down 1140 ft., or 170 ft. below the tenth level. A station will be cut when a point 30 ft. deeper has been reached. The shaft is in diabase.

(Special Correspondence.)—J. Parke Channing, who is at the Miami mine, said in an interview this week: "The compressed-air hoists at shaft No. 4 are surpassing my expectations in their smoothness of running. I think this is the coming way of hoisting when long transmission of power is an imposed condition. The early difficulties encountered in the power-plant have been overcome, and we are getting good figures on evaporation and steam consumption. One generator easily carries the whole load of 1000 to 1200 kw., including the pumps at Burch. The fourth section of the mill has just started at full capacity, the Burch rolls in this section being followed with two 8-ft. Hardinge pebble-mills instead of Chilean mills. One Hardinge mill has been in operation in this section for the past month and the results have been satisfactory. We will now give the two mills a good test and compare the cost of the silica lining and pebbles of the Hardinge with the cost of steel and screens of the Chilean. While the capacity of the mill was originally figured at 2000 tons per day, I have no doubt that the ultimate capacity, with all six sections running, will be 3000 tons. The mill extraction for August was 76%, and I think this will be increased to my original estimate of 80%. A duplicate 400-hp. motor is being installed in the pumping plant at Burch. In one section of the mine near the periphery of the orebody, we are cutting out under the capping and placing light square-sets. The capping is caving of its own weight, and the timbers are being crushed, forming a mat between the ore and the capping. In another section we are working three shrinkage stopes and getting two more started. The main cross-cut on the 570-ft. level has been started. We had ore in No. 2 shaft from the 270-ft. level all the way down to the 720-ft. level. While I have always figured on a cost of 9c. per pound, I think we can attain a lower figure."

Miami, September 29.

Pima County

The Arivaca Gold Mines Co., which is being financed in New York, has bought the Union group of seven claims, state late newspaper articles. Development work is to be started this month.

The Copper Queen Con. M. Co. has made payments aggregating $4250 on options on property in the Old Hat district near Tucson. An amended agreement with F. Geeseman has been filed on the Eagle, Copper Peak, York, Eagle No. 2, and Golden Peak No. 2. The balance due on these claims, $59,750, is to be paid on August 15, 1912.

Pinal County

Four units of the Ray Con. Copper Co. have been in operation for over a week, and 3200 tons of ore per day has been treated. The fifth unit will be placed in operation probably late in October. It is believed that this month's production will exceed 2,500,000 lb. of copper. The main source of production has been No. 1 shaft, which is down 270 ft. No. 2 shaft, in the near future, should be a regular producer. Two-thirds of the company's proved supply of about 80,000,000 tons of ore is above the 270-ft. level.

The Ray Central Copper M. Co. is planning to build a 1500-ton mill in the near future and set up other equipment. Frank R. Probert is engineer for the company, which has its mine office at Ray.

CALIFORNIA

Eldorado County

By order of the Superior Court of Los Angeles, the Lucky Baldwin quartz mine, near Nashville, has been sold to M. Effinger for $40,000. Effinger is to pay $20,000 cash and the remainder within two years. H. A. Unruh, executor of the Baldwin estate, is authorized to collect 20% of the gold produced until full payment has been made.

Inyo County

The Skidoo Mines Co. in August produced bullion to the value of $15,381, and, with the cyanide receipts had a total income of $19,212. During the month $627 was spent on development and $9924 on operation, leaving a net profit of $9660.

Nevada County

L. B. Doe, of the Union Hill M. Co., has purchased a diamond-drill to prospect below the 600-ft. level. This method is an innovation in the district, and it is believed that the results will be of value to the whole district. The shaft is to be sunk to a depth of 2000 feet.

Sierra County

(Special Correspondence.)—The Sierra Buttes Mines Co. is developing and blocking out ore in the No. 6 adit along the Serpentine-Porphyry contact vein and dropping 15 of the 20 stamps in the upper mill. The tailing is sluiced to a cyanide leaching plant at the No. 9 mill and treated for a period of four to seven days. The flume is six miles in length, bringing an unlimited supply of water for power from the Sardine, Salmon, and Summit series of lakes, that at a minimum flow can furnish 20,000 electrical horse-power, available from a 1700-ft. fall. The construction of two hydro-electric plants is being considered by the company. The mines and water-power are owned by E. A. and J. O. Hayes of San Jose. J. C. Folsom is superintendent.

The Sovereign M. Co. is completing the installation of two Beer roller mills and is to begin milling some time in October. F. O. Richardson is superintendent.

The Grey Eagle M. Co. is repairing its 10-stamp mill at Gold Point, about five miles below Sierra City, and expects to be operating at full capacity during the latter part of October. W. F. Arbuckle is superintendent.

Sierra City, September 30.

Trinity County

The Union Hill M. Co. has sold the Union Hill mine, near Douglas City, to New York capitalists represented by W. A. Boland. The last payment has been made. The property is a hydraulic placer mine, and five years ago was sold for $180,000, according to newspaper reports. Since then about $250,000 has been spent in building a 20-mile canal and pipe-line. The price paid this time is believed to be close to $500,000.

Later despatches affirm that Mr. Boland is believed to be representing the Guggenheims, and quote him as saying that he has completed all arrangements for acquiring all placer properties in the Weaverville basin, extending along the Trinity river for 5 miles, close to Douglas City. Over 20 groups are included in the deal, and the total price is believed to be between $10,000,000 and $15,000,000, exclusive of the La Grange. Among the leading properties are the Union Hill, Douglas City, Testy, Fields, and other hydraulic mines.

Tuolumne County

(Special Correspondence.)—Ore rich in free gold has been uncovered in the Gem mine, near Confidence. The property is owned and operated by J. M. Wulzen.

A new hoist has been installed at the Wheal Ruff, situated near Soulsbyville, and sinking was resumed a few days ago. In the new shaft, which is 20 ft. deep, the vein is only a few inches in width, but has rich free-milling ore. According to the conditions of the bond, sinking must be continued for 200 ft. and drifts then driven at both the first and second levels, the one to the east at the bottom to be extended into the Frank Burns claim, which adjoins the Wheal Ruff. The property was bonded a few months ago to W. C. Austin, of Nevada City, for $16,000. George W. Richards is superintendent.

It is understood that general mining operations will begin at the Starr King not later than November 1. Nearly all the machinery to be put in is on the ground, and the 5-stamp mill will be completed about October 20. Four electric motors with an aggregate capacity of 100 hp. will be used in the operation of the plant.

Three quartz claims adjoining the Shawmut mine and owned by the Gold Ridge M. Co. have been bonded to Clarence Woods, of Tuolumne, who represents Eastern investors in the transaction. A hoist and a compressor will be installed at once and the work called for in the bond commenced as soon as possible.

Tuolumne, September 30.

Work will soon be resumed at the Keltz mine, state reports from Sonora. A. L. Huston of Chicago is in charge of the preliminary work for reopening the mine.

Concrete mortar blocks are being placed for the additional 20 stamps of the mill of the Dutch mine, and the stamps will be dropping within 60 days. An electric hoist and compressor are planned, and the mine will be unwatered for deeper exploration. The shaft is now down to the 900-ft. level. G. Metz has bought the Longfellow mine at Big Oak Flat.

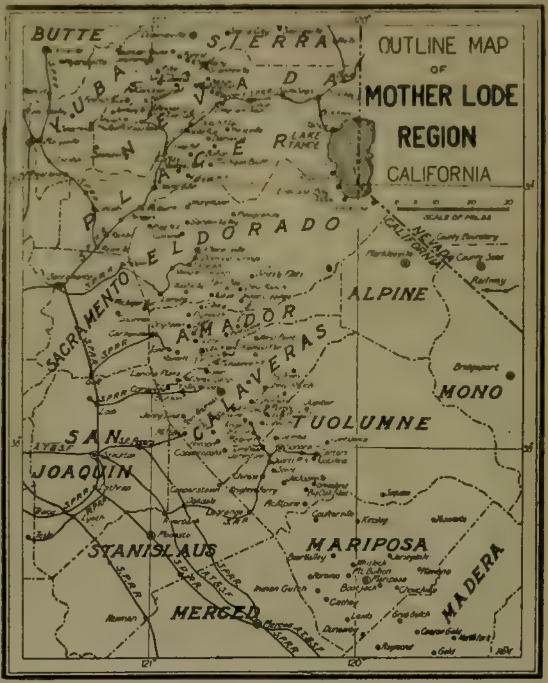
Yuba County

Remarkably rich gold ore has been discovered on the ranch of Joseph Rose, in the Dobbins district, state reports from Marysville. Ore shipped to the Selby smelter is reported to have yielded $15,000 per ton. The mine is near the Red Ravine property.

(Special Correspondence.)—The Indian River Drift M. Co., situated about seven miles from Camptonville in the Orient district, is building housing for the miners and accommodations, and constructing tanks, sluice-boxes, and the necessary piping for active drift gravel mining. An adit about 2500 ft. long has been run to the rim of an old channel, and after going through 200 ft. of the rim-rock gravel on bedrock, it was decided that a complete washing plant should be erected. The entire channel will be worked by the pillar and caving system, thereby doing away with handling the large boulders. The company will have 30 men at work in a few weeks handling full capacity. W. L. Breese of Four Oaks is manager for the company.

J. P. Lyon, of Vacaville, has arrived to open the Rube St. Clair mine, seven miles east of this town. The property has been bonded to Mr. Lyon for six months, and as all indications from sampling have been excellent, a force of men will be put to work on development.

The Two Grit Drift M. Co., 9 miles east of Camptonville, is opening up a property which paid rich returns 25 years ago and has every prospect of duplicating its past record. R. H. Deal is foreman of development. W. B. Meek is owner and manager.



Camptonville, September 26.

COLORADO

Clear Creek County

(Special Correspondence.)—The capacity of the Leebrick mill is to be doubled. Ore from the mines being operated through the Central adit is being treated. A. W. Doud & Co. are installing the Johnson electro-chemical process in the McCormick mill situated on Chicago creek. Ore from the P. T. mine will be treated. A. Anderson, lessee on the Papoose mine on Seaton mountain, has made arrangements with the Blue Bell M. Co. to treat a heavy tonnage of ore in the company mill. The machinery is being placed in position in the Combination mill on Water street, and ore treatment will probably be started inside of 30 days. Work is progressing in the removal of the machinery at the Idaho Reduction Works preparatory to equipping the plant with the Motter process. O. W. Lowell is manager. A body of ore 14 ft. wide has been found in the breast of the Lucania adit that shows assay values varying from $4 to $52 per ton in gold.

Idaho Springs, September 26.

(Special Correspondence.)—The Burleigh mill is again running after a shut-down of two weeks. George Tarkington is operating under lease. The Mineral Chief mine and mill have been taken under lease by A. L. and P. T. Stephens and John W. Old. Operations were put under way Monday. Report is current that work is to be resumed on the Kelly adit, the portal of which is situated on Democrat mountain. H. O. Marcy of Boston is owner. Work has been resumed on the Big Blue property, situated on

Saxton mountain. A. Santo is owner. An 8-in. streak of gray copper has been uncovered in the west drift of the Kirtley vein that is worth 227 oz. silver per ton. E. S. Weaver is owner. A streak of smelting ore 12 in. wide is showing in the drift on the Riley vein that is worth 80 oz. silver per ton.

Georgetown, September 27.

The Linn M. Co.'s property has been leased for five years to A. L. and P. T. Stephens and J. W. Old. Repairing the mill will be started immediately, and a short tramway will be built from the Boston dump to the workings above, according to reports from Georgetown.

Teller County

The Pride of Cripple Creek, on Ironclad hill, will be started up in the near future, after being closed down for several months. The Pride M. & L. Co. is the lessee. Fred Johnson is superintendent of the property. It is believed shipments will be started in a short time.

New machinery for finer grinding will be placed in the Homestake mill on Globe hill, according to Joseph Cooper, president of the Cripple Creek Cyanide Co., which is operating the mill under a lease from the Rex M. & M. Co., state recent reports from Cripple Creek. The mill is undergoing repairs incident to the breaking down of a set of rolls.

IDAHO

Idaho County

Fifty thousand dollars in bonds has been voted by the stockholders of the Mizpah M. & M. Co. to purchase machinery and equipment for the mine. The property consists of 18 claims in the Hoodoo district. A gasoline truck will be used to carry the ore to the railroad, over a natural road of 18 miles. J. C. Northrup, general manager, is directing the installation of an air-compressor and drills on the property. The company has offices at Spokane, Washington.

Lemhi County

The Wilber M. Co., near Gilmore, is about to start construction on a 100-ton mill, and the machinery is said to practically have been contracted for. M. M. Johnson is consulting engineer for the company.

Shoshone County

(Special Correspondence.)—On Wednesday, October 4, the Bunker Hill & Sullivan M. & C. Co. paid dividend No. 169, of $65,400. This makes the total amount of dividends paid $13,028,850.

Kellogg, October 5.

William T. Tracy, of Galesburg, Ill., has purchased the Amazon-Manhattan group. The price is reported to have been $300,000. The property consists of eight patented claims on Carbon creek, on the west slope of Sunset peak. For the last 12 years the claims were owned by the estate of B. N. Hillard, H. M. Davenport, Ben S. Revett of Colorado, and C. M. Asp.

A 14-ft. vein of rich silver-lead ore has been found in the 2000-ft. adit now being driven on the Nabob M. Co.'s property, state reports from Wallace. The discovery is said to be the richest yet made in the Pine Creek district.

The report of the Snowstorm M. Co. for the year ended June 30 shows that in that period dividends amounting to $44,985 were paid. During the year 34,463 tons of ore assaying 7.98 oz. silver and 3.93 oz. copper per ton was mined. The gross receipts were $171,384, and the net earnings for the year were $26,691. The small tonnage of ore is reported due to unfavorable market conditions. Leo Greenough has been elected president to fill the vacancy caused by the death of his father.

The Snowshoe M. Co., operating a property of the same name near Mullan, says in its statement that the development of the mine, driving adit, getting in wood, building roads and pipe-line, and clearing ground to avoid possible loss from forest fires, has cost $11,072.93, making a total expenditure of $14,858.70 for the year. The company now has everything in good shape to push the development work ahead. Seven hundred feet of adit remains to be driven to reach the point where the vein should be cut. This, it is announced, will place the property on a paying basis.

C. W. Clark, son of W. A. Clark, stated in an interview in Spokane that his father would begin systematic development at the Sunset mine in the Coeur d'Alene in the spring. A 5-drill compressor has been erected at the Nellie mine of the Wallace Development Co., near Osburn, and a hoist and 75-hp. motor are on the ground ready to be erected. Later on a small mill for concentrating will be constructed.

MONTANA

Lincoln County

(Special Correspondence.)—The Snowshoe mine now has a force of men at work on Cherry creek, on the opposite side of the mountain from the mine workings, who have started to run an adit to cross-cut the vein. This adit will cut the vein about 1000 ft. below the present workings. The adit will be 5½ by 7 ft. in the clear. The company is shipping in 60 head of horses to be used in transporting ore and supplies. A motor truck was experimented with for this work, but the one that was tried lacked power to do the heavy hauling and the company has now decided to use horses.

Libby, October 2.

Silverbow County

(Special Correspondence.)—T. F. Murray of St. Paul, and A. B. Wolvin of Duluth, president of the Butte & Superior Co., with several local capitalists, have organized the Black Diamond Gold Mining Co. with a capital of $700,000, divided into shares at $1 each, the principal place of business to be at Butte. The property secured by the company is in the Radersburg district, and is said to be surrounded by some properties which are now producing.

Butte, September 30.

Excavation has been started for the Butte & Superior concentrator, state Butte despatches. The machinery will be taken from the Basin reduction works.

Denial from a high source has been made in regard to the rumor that the Tuolumne Copper M. Co. will pass the next dividend. Extraordinary demands on the treasury will be made in the near future.

NEVADA

Clark County

After inactivity covering a year and a half, work has been resumed in the Fraction shaft of the Duplex property, owned by G. F. Colton, according to despatches from Searchlight. R. H. McCreary, of Hanford, California, has taken over six lead-zinc claims in the Yellow Pine district. The claims were the property of Richard Feaster.

Esmeralda County

(Special Correspondence.)—At Lida, one of the earliest producing camps of southern Nevada, the New York Smelting & Mines Co., headed by A. A. Redmond, and in which San Francisco investors are interested, has acquired two of the early producers and is developing on a good scale. The old Centennial mine is being developed and cross-cuts from the main shaft on the 192-ft. level have proceeded for over 200 ft. in ore with only the hanging wall in sight as yet.

Goldfield, October 2.

(Telegraphic Correspondence.)—Estimated September production of the Goldfield Con. M. Co., 26,766 tons; gross value recovered, $650,000; operating expenses, $225,000; net profit for month, $425,000. Mines are looking well. These figures are from a recent report prepared by A. H. Howe of the company.

Goldfield, October 3.

The State bullion tax collector has reported an increase of 12% in the production of this county for the last quarter.

Control of the Silver Pick M. & M. Co. has been acquired by a group of men headed by Herman Zadig, according to recent newspaper despatches, and the company has been reorganized on an assessable stock basis under the name of the Silver Pick Con. Mines Co., capitalized at $1,500,000. Mr Zadig is president, and E. S. Van Dyck is treasurer and manager. The main office will be in the offices of the Florence Goldfield company in Goldfield. The properties owned are the Silver Pick, Silver Pick Fraction, Northend, Deserted, and Pipe Dream claims, adjoining the Combination and January claims of the Goldfield Con. M. Co., and the Webfoot claim in the Hornsilver district. Development is to be started on the Silver Pick property at an early date. The monthly report of J. F. Thorn, general superintendent for the Goldfield Con. M. Co., shows that in August a new tonnage record for the company was made, 30,580 tons of ore, valued at $910,477, or an average of $29.77 per ton. A new record was made at the mill, which during the month treated 30,508 tons, or an average of nearly 1000 tons per day. The net profit for the month was $634,658. The total operating cost was $7.53 per ton. During the month 3744 ft. of development work was done.

HUMBOLDT COUNTY

The Indian Con. M. Co., capitalized at $5,000,000, has taken over the Limerick, Plainview, and other groups of claims in the Limerick canyon district, and is planning extensive development work. M. C. Scully is the organizer of the company, which was formed under the South Dakota laws.

GOLDFIELD CON. MILL.

LANDER COUNTY

A 100-ton concentrating and milling plant is being erected at the Jersey Valley mine, which is owned by George W. Abel.

MINERAL COUNTY

(Special Correspondence.)—At Douglass, a camp that produced some $600,000 in bullion during the early nineties, G. C. Webb, who some time ago purchased the Tennessee group, has shipped several cars of high-grade ore to the sampler of the Western Ore Purchasing Co. at Hazen and has exposed ore of shipping grade at four or five points on his claims. At one point average assays across 3 ft. yielded around $200 per ton, and farther up the mountain samples taken across 15 ft. gave an average of $50 per ton. The ore is free milling throughout and the veins are between well defined walls wherever they have been opened.

Goldfield, September 25.

NYE COUNTY

(Special Correspondence.)—The Steen-Poak-Cicala lease has opened on the 400-ft. level of Big Four what appears to be an entirely new orebody. It was intersected by the cross-cut which is being driven to tap the main Big Four vein. Driving now under way continues and it is expected will intersect the main vein within a few days. A heavy flow of water has developed on the 400 ft. level, and another pump has been erected. No further trouble from this source is anticipated. The winze from the 285-ft. level is reported going down on ore averaging $54 per ton. It is understood that sinking will be resumed from the 400-ft. point shortly. The Big Four is now the deepest mine in Manhattan, with the orebody showing satisfactorily. The War Eagle mill is operating on ore from Union No. 9 claim, on Manhattan Dexter estate. About 40 tons per day is treated, the ore coming from above the 235-ft. point. The ore is reported to assay from $35 to $40 per ton. The Putman-Kendall lease on the Jumping Jack has been incorporated under title of the Manhattan-Jumping Jack Leasing & Mining Co. Reports are current of important developments on Mineral hill, but the management has not confirmed stories of a recent rich discovery. It is understood, however, that good ore is being opened.

Manhattan, September 29.

STOREY COUNTY

The Crown Point G. & S. M. Co. made a profit of over $5000 during August, according to officers of the company. A mill-run of 1690 tons showed an average return of about $9 per ton. The mill run was made in addition to regular development work. Pumping arrangements will be made in a few months so as to work below the 1400-ft. level.

The discovery of 3 ft. of quartz of low assay value in the bottom of the Union & Sierra Nevada winze has raised hopes of finding valuable ore. A point 562 ft. below the 2000-ft. station, where it was planned to stop, has been reached, and sinking will be continued for the present.

The south drift from the west cross-cut on the 2400-ft. level of the Ophir is in a strong vein.

WASHOE COUNTY

Ore assaying $591 per ton was discovered recently on the property of the Nevada United Mines Co., by Edwin Arkell, according to press reports. The cross-cut in which the ore was found is at a depth of 131 ft. The ore was found about 40 ft. from the shaft.

WHITE PINE COUNTY

The Ohana M. Co. at Sacramento pass is about to erect a 60-hp. gasoline hoist and a 4-drill compressor, which have been shipped to the mine. Four Chicago 2¼-in. air-drills also have been ordered. The main shaft, now 100 ft. deep, will be sunk 200 ft. deeper, if water is not found at the lower levels.

NEW MEXICO

SOCORRO COUNTY

(Special Correspondence.)—The two clean-ups of the

Ernestine M. Co. for the first and second 10-day periods of September resulted in 10,376 oz. of gold and silver bullion, with 7½ tons of high-grade concentrate. The ore treated the past two weeks amounted to 1160 tons. The new power-house is nearing completion and the equipment for the same will arrive in Silver City in about two weeks.

Work will be started on the new buildings of the Oaks Co. at the main drainage and transportation tunnel within a few days. The adit is being steadily advanced.

Further development will be started on the Trilby group claims about October 1.

Work in the new shaft of the Maud Mining Co. and drifts therefrom has been temporarily suspended. Good ore has been found, and it is said full operations will be in force within a few days.

Mogollon, September 29.

UTAH

SALT LAKE COUNTY

The Utah Copper Co. this year will produce more than 100,000,000 lb. of copper, state advices from Boston. The 9,000,000-lb. output of August will be exceeded in the last four months of the year. The company has never carried surplus stocks of unsold copper. It is believed that an 8c. cost can be maintained. With the prospect of an annual production of 140,000,000 lb. of copper, made possible by the Magna and Arthur mills, and the completion of the Bingham & Garfield railroad, it is believed that $3 dividends can be continued with copper at 11½c. per pound. This estimate was made aside from the equation of ownership in the Nevada Consolidated.

The Ohio Copper Co. has ordered 20 Wall rolls from the Salt Lake Engineering Works for the Ohio mill. Four rolls are now in operation, a fifth is under way, and the other fifteen will be in operation, it is believed, within three months, giving the mill a capacity of 3000 tons per day.

SAN JUAN COUNTY

The town of Mexican Hat, in the Goodrich basin, is getting illuminating and cooking gas from new wells being sunk by the Producers Oil Co., a Kansas City corporation. Some oil also is coming from the well, which is down 660 ft., state newspaper reports. The town is the first in Utah to be lighted by natural gas. Work is being resumed at many of the oil properties in the San Juan field.

SUMMIT COUNTY

The Daly West M. Co. has declared a dividend of 30c. per share, payable October 20. The dividend will mean a disbursement of $54,000. The total in dividends paid by the company will then be $6,255,000, of which $162,000 will have been paid since the first of the year.

CANADA

ONTARIO

The Kerr Lake M. Co., in the year ended August 31, produced 2,388,420 oz. of silver, against 3,046,295 oz. a year ago, at a cost of 14.69c. against a cost of 13.27c. per ounce for the previous year. The development work of the year resulted in the discovery of six new veins in the No. 7 shaft workings. The recent extra dividend was cut from 25c. to 15c. The company paid during the year $1,200,000, while its net profit for the year was $937,379. The dividends paid last year amounted to $990.000.

The net production of the Temiskaming & Hudson's Bay M. Co. for the year ended August 31 was slightly larger than for the previous year, although dividends were slightly less, owing to the purchase of the Gowganda properties, the erection of a mill, and other heavy expenditures. The gross revenue from ore, rents, ore adjustment, and $957 from the Gowganda ore, was $403,412. Total expenditures were $173,362. Dividends paid amounted to $181,501. A balance of $111,188 remains in the treasury after a stock discount of $40,000. Since January 1 the company has maintained a force about double that of previous years. The cost of producing silver was about 14.9c. per ounce for the total production of 804,624 oz. of silver for the year. The total output cost in production $120,055, leaving a profit of $288,973. During the year a concentrator has been erected, and a new shaft-house, pump-house, and transformer house have been built. George Taylor was elected president of the company. The meeting was held in New Liskeard, September 25.

A new vein was found during exploration work on the McKinley-Darragh property near Cobalt. About ten cars of high-grade ore per month are sent to the smelters.

It is reported that Mackenzie & Mann have purchased the Goselin property, in Shining Tree district, for $30,000 cash. The deal is reported from Sudbury.

PRINCE WILLIAM SOUND

The Mayfield group of claims has been acquired by M. M. Reese, president of the Ibex company, and associates, state Valdez reports, and a $1,000,000 corporation known as the Mayfield Gold Mining Co. has been formed to develop the claims.

YUKON

The Dominion Government's report on the Yukon, recently issued shows that since the discovery of the rich placer mines in 1897 the Yukon has produced $136,500,000 worth of gold. The production increased from $300,000 in 1896 to $22,275,000 in 1900, from which it decreased, owing to the exhaustion of the richer gravels, to $3,150,000 in 1907. The production for 1910 was $4,550,000. Large companies are carrying on extensive operations for working over the old tailings and the large deposits of low-grade gravel.

Five tons of native copper from the Solomon mine in the heart of the White River district recently was taken to Dawson. The copper, which is the finest seen in the Yukon, according to Dawson despatches, was brought in by Solomon Albert, Joseph Slaggard, and James Kingston.

A rich vein has been found on the Conrad property near Carcross. The tunnel is in about 1750-ft. and has penetrated several highly mineralized orebodies, state newspaper reports. A 250-hp. electric plant is being set up at the mouth of McDonald creek, on the railroad, five miles south of Carcross.

Rich gold discoveries have recently been made in Dublin gulch. The gold can easily be washed with a pan, state press reports, and several men are working on the vein. Efforts are under way to have a quartz mill constructed there, according to B. C. Sprague, in an interview at Dawson.

MEXICO

CHIHUAHUA

(Special Correspondence.)—The San Toy in August shipped 33 cars of ore, of which the gross value was ₱207,546.

Chihuahua, September 30.

SONORA

Rich ore has been found in the Klondike district, 65 miles southeast of Magdalena, according to newspaper reports. The vein was traced from the Patsy claim to free ground by Jesus Villalva, who, with associates, denounced 10 *pertenencias*. Another denouncement, covering 21 *pertenencias*, and named the Juan Cabral, was made by Holt brothers.

The Mexican Metals Co. will resume operations in the Arizpe mines as soon as the necessary help can be secured, according to an announcement by August Fritsche, president and manager. The property was formerly owned by the Arizpe M. Co. Work probably will be started in the Alacran and Palo Seco shafts.

The Mexican company owning the La Junta mine is reported to be negotiating the purchase of the custom mill at Sobia, where its milling ore is treated. The company in the past has treated rich ore in Mexican furnaces, or *rascos*. The Piedras Verdes mine has been acquired under option from José M. Quirez by Boston investors. The property lies in a low-grade copper district about ten miles from Alamos.

Zinc sheet, No. 9—18 by 84, drum, 100 lb.	9.75	10.75

Current Prices for Ores and Minerals

(Corrected monthly by Atkins, Kroll & Co.)

The prices are approximate, subject to fluctuation, and to variation according to quantity, quality, and delivery required. They are quoted, except as noted, f.o.b. San Francisco. Buying prices marked*.

	Min.	Max.
Antimony ore, 50%, per ton	*$20.00	$25.00
Arsenic, white, refined, per lb.	0.01¾	0.02¼
Arsenic, red, refined, per lb.	0.06¾	0.07¼
Asbestos, according to length and quality of fibre, per ton	100.00	350.00
Asbestos, lower grades, per ton	10.00	100.00
Asphaltum, refined, per ton	15.00	20.00
Barium carbonate, precipitated, per ton	42.50	45.00

Barium chloride, commercial, per ton	37.50	42.50
Barium sulphate (barytes), prepared, ton	20.00	30.00
Bismuth ore, 10%, upward, per ton	*75.00	upward
Chrome ore, according to quality, per ton	10.00	12.50
China clay, levigated, per ton	15.00	20.00
Cobalt metal, refined, f.o.b. London, per lb.	2.50	
Coke, foundry, per 2240 lb.	15.00	17.50
Diamonds:		
Borts, according to size and quality, per carat	2.00	15.00
Carbons, according to size and quality, per carat	75.00	100.00
Feldspar, per ton	5.00	25.00
Firebrick:		
Bauxite, per M	175.00	
Magnesite, per M	190.00	275.00
Silica, per M	42.50	47.50
Flint pebbles for tube-mills, per 2240 lb.	15.00	25.00
Fluorspar, per ton	10.00	15.00
Fullers earth, according to quality, per ton.	20.00	30.00
Gilsonite, per ton	35.00	40.00
Graphite:		
Amorphous, per lb.	0.01½	0.02½
Crystalline, per lb.	0.04	0.13
Gypsum, per ton	7.50	10.00
Infusorial earth, per ton	10.00	15.00
Magnesite, crude, per ton	7.50	10.00
Magnesite, dead calcined, per ton	22.50	27.50
Magnesite, brick (see firebrick).		
Manganese ore, oxide, crude, per ton	10.00	25.00
Manganese, prepared, according to quality, per ton	30.00	70.00
Mica, according to size and quality, per lb.	0.05	0.30
Molybdenite, 95% MoS_2, per ton	400.00	500.00
Monazite sand (5% thoria), per ton	150.00	200.00
Nickel metal, refined, per lb.	0.45	0.60
Ochre, extra strength, levigated, per 100 lb.	2.25	3.25
Platinum, native, crude, per oz.	30.00	40.00
Scheelite (see tungsten ore).		
Sulphur, crude, per ton	15.00	25.00
Sulphur, powdered, per ton	40.00	45.00
Talc, prepared, according to quality, per ton.	20.00	50.00
Tin ore, 60%, per ton	450.00	475.00
Vanadium ore, 15%, per ton	150.00	180.00
Vanadium ore, 15%, per ton	200.00	250.00
Wolframite (see tungsten ore).		
Zinc ore, 50% up, per ton	*15.00	20.00

Obituary

JOSEPH H. FRAZER, of Newark, Delaware, a young contractor and engineer, died of pneumonia at La Paz, Bolivia, after seven days illness. Mr. Frazer was a son of Eben B. Frazer, and was born in Maryland about 28 years ago. He was graduated from Delaware College in 1903, spent two years in the engineering department of the B. & O. railroad in Pennsylvania, Maryland, and West Virginia. In 1905 he was employed as engineer with the Commission for the Study of Railways of the Bolivian Government. From 1905 to 1907 he was chief engineer of the Andes Tin Co., which position he resigned to form with William R. Rumbold, of Tunbridge Wells, England, the firm of Rumbold & Frazer, mining engineers, Oruro, Bolivia. In 1909 he sold his interest in the above mentioned firm to A. Basil Reece in order to form with Adam W. Yount the contracting and engineering firm of Yount & Frazer, Bolivia. The firm took and completed successfully contracts for the construction of important railways in Bolivia, among them being large parts of the lines from Rio Mulato to Potosi and from Oruro to Cochabamba. Mr. Frazer was one of the few Americans who ably managed important contracts with the native labor, and although a young man, by hard work and careful judgment, was able to amass a considerable fortune in a few years. Mr. Frazer was a man of high ideals and lovable character and leaves a record of clean, honest work, and was one of the most popular foreigners in Bolivia. He was a member of the American Society of Civil Engineers.

The Royal Society of Arts, London, has awarded a gold medal under the Fothergile Trust to the self-contained breathing apparatus manufactured by SIEBE, GORMAN & Co. LTD., under the Fleuss and Davis patents. The award was based on tests made at Birmingham University.

The Anaconda Copper Co., Butte, Montana, has placed an order with the GENERAL ELECTRIC Co. for 13 locomotives.

Personal

Professional men are invited to send news of their engagements and travels. Such news is interesting to friends.

ALBERT BURCH has returned to San Francisco.

M. L. REQUA will be in New York next week.

E. A. PECKEY, of Goldfield, is in San Francisco.

ALEXANDER P. ROGERS will return to New York soon.

GEORGE H. GARREY has gone to Plumas county, California.

ELLARD W. CARSON, of Los Angeles, is at Goldroad, Arizona.

COURTENAY DE KALB has gone to Shasta county, California.

J. W. MALCOLMSON has returned from a summer in Europe.

ROSS B. HOFFMANN returned to San Francisco this week from London.

VERNE A. HART is examining the mines of the Arizona Copper Co. at Metcalf, Arizona.

J. MALCOLM MACLAREN has completed his work at Porcupine and is at Cobalt, Ontario.

L. R. BUDROW and L. H. FORBES will be among the visitors to San Francisco next week.

CHARLES G. S. GORDON has left the Bote Mining Co. of Zacatecas, and is now at Mexico City.

F. G. COTTRELL has returned from Montana and will be in San Francisco for the next few weeks.

R. B. MCGINNIS has returned to Berkeley, California, from a seven months trip to Brazil and Bolivia.

CLIVE S. NEWCOMB has removed his offices from No. 32 Avenida Cinco de Mayo to Edificio La Mutau 414, Mexico City.

E. M. HAMILTON has returned from England and expects to spend the month of October at the El Rayo mine, at Santa Barbara, Chihuahua, Mexico.

CHARLES KIRCHHOFF, who is this year president of the American Institute of Mining Engineers, is unable to attend the meeting at San Francisco, owing to sickness in his family.

R. R. FOSTER has resigned as superintendent of the mill and cyanide plant of the La Tula Mining Co. at La Luz, Guanajuato, and is taking over the engineering business of Lineberger & Rone.

DOUGLAS D. STAVELEY has given up the position as manager of the Sintoeroe mine, Sambas, Dutch West Borneo, where he has been for four and a half years, and is on his way back to London.

The Western members of the *Mining and Metallurgical Society of America* will dine October 16 at the Fairmont Hotel. The subject for discussion will be 'The Revision of the Alaska Land Laws.'

CHARLES H. FULTON has resigned the presidency of the South Dakota School of Mines to accept the chair of Metallurgy and acting head of the Mining Department of the Case School of Applied Science, at Cleveland, Ohio.

Among those who will attend the meetings of the American Institute of Mining Engineers at San Francisco next week are: W. H. ALDRIDGE, W. S. AYRES, W. B. CLARK, H. C. FARNUM, CHARLES W. GOODALE, ROBERT W. HUNT, WILLIAM R. MCILVAIN, E. B. MATHEWS, F. H. MORLEY, R. W. RAYMOND, W. L. SAUNDERS, JOSEPH STRUTHERS, EDWIN THOMAS, and BENJAMIN W. VALLAT.

THE 15-ft. dredges described on another page are two of five designed and built by the YUBA CONSTRUCTION Co. of Marysville, California, during the past year. A sixth, embodying certain improvements, including a steel hull and designed by the same company, is now under construction.

EDITORIAL

SAN FRANCISCO will entertain the President today, and he, being a believer in reciprocity, will entertain San Francisco.

TELEGRAPHIC despatches record that Mr. J. D. Rockefeller has said that young men should take lots of exercise if they wish to keep healthy. Brokers please note this important information.

GOLD bars valued at $1,500,000 were delivered by the Government assay office at New York last week for shipment abroad and the use of gold bullion instead of coin for foreign exchange is likely to prove popular.

TONOPAH, properly enough, is congratulating itself on a probable dividend record for this year of $3,120,000, of which the larger part is derived from the Tonopah Mining Company and the Tonopah Belmont Development Company.

CHICAGO will entertain the American Mining Congress October 24 to 28, and a handsome booklet recently sent out by the central committee gives brief reviews of the many important topics which will come up for discussion. With the President of the United States, the Secretary of the Interior, the Director of the Bureau of Mines, and other notable men in attendance, the meeting assumes a semi-official air and results of permanent value should be attained.

SETTLEMENT of the labor dispute at the Veteran mine at Ely is officially announced. The miners have agreed to forego recognition of the Western Federation and the company has made concessions as to leases and the wage scale for underground work, thus making possible the resumption of working, and it is reported that ore won underground will be used to regulate the production of the Nevada Consolidated during the winter months when climatic conditions hamper the work in the open-cuts.

JAPAN a scant half century ago was a hidden land which, industrially, was organized as was Europe in the Middle Ages. Now it is a great modern nation. Sons of men who served the Shogun today manage enterprises that are extremely modern and some of which rival in size the great American corporations misnamed 'trusts.' Since Nippon first opened her gates to the world the relations between the Island Empire and the United States have naturally been close. Americans and Japanese are cooperating in mining ventures in Korea and elsewhere. Mr. Toranosuke Furukawa, owner and director of the Ashio mine, elsewhere described, is by no means the only Japanese mining engineer trained in America. The American Institute of Mining Engineers has a considerable membership resident in the Islands, and it is appropriate that an occasional meeting should be held there. To the sessions to be held in Tokyo next month a large delegation of American members of the Institute are going. They take with them from the larger number who cannot make the trip, the sincere good wishes for the health and prosperity of their Japanese associates in the profession, and for their country.

“IN mining there is no royal road to success,” pertinently remarks the *West Australian Mining, Building & Engineering Journal*. “The best men come to the top through ability, diligence, and honesty, and if these attributes be backed up by a good mine and liberal capitalists at head of the stockowners, then something like success may be claimed by the mining engineer. The average director in Australian companies, however, pays too small a salary to command the services of good men. Mines, as a consequence, suffer for want of scientific men to control them.” To this we would add that the problem is by no means confined to Australia.

RESIGNATION of Mr. C. W. Hayes, chief geologist of the United States Geological Survey, takes from the public service another of those engineers who have given distinction to the technical work of the Government. It is understood that Mr. Hayes is to devote his time hereafter to professional work in connection with the Mexican oil industry. For this he is especially qualified, having in fact served for two years as consulting geologist for the companies controlled by Lord Cowdray. His work as a geologist and explorer is well known and he is an executive of proved ability. While in charge of diamond-drilling for the Nicaraguan Canal Commission, as well as in numerous missions for the Government, he has had much engineering experience and is sure to do well in his new work.

NO APOLOGY is necessary for devoting so much space this week to the meeting of the American Institute of Mining Engineers. The sessions and the excursions both at Los Angeles and San Francisco have been of much technical interest and have served greatly to reinforce that solidarity of interests so important among professional associates. We print abstracts of a number of the papers presented, and others will follow in later issues. One of our Editors will accompany the party of engineers going to Japan, and we can promise a full account of the trip, which is sure to prove of much professional and personal interest. In the meantime, as the engineers scatter by steamer and train, to the mine, the mill, and the office, we give them the word which so fitly expresses the Western spirit of welcome—Mizpah.

DEFINITE STEPS have been taken to raise a fund for a memorial commemorating the life and work of S. F. Emmons as suggested in our issue of April 22. A committee consisting of Dr. James Douglas, chairman, J. Parke Channing, J. F. Kemp, F. W. Bradley, H. L. Smyth, Benjamin B. Lawrence, Seeley W. Mudd, David D. Brunton, T. A. Rickard, George Otis Smith, J. A. Holmes, and H. Foster Bain, has been formed to take charge of the matter. It has been determined to endow a research fellowship in economic geology at Columbia University, the first school of mines in the United States, an institution of which Emmons was an honorary alumnus, and one with which he had many close ties. We can conceive no more appropriate tribute to the geologist who did so much to bring geology to the aid of mining. The successive holders of the fellowship will keep alive the Emmons spirit of patient, accurate, scientific work as a prerequisite to economical exploitation of orebodies. We are sure the committee could not have chosen a memorial that would have better pleased Emmons himself. To carry out the plans formulated it will be necessary to raise approximately $25,000. Of this sum a tenth was subscribed at the first meeting of the committee, held in New York this week. The full amount should be secured quickly and engineers and geologists are requested to send their subscriptions promptly to Mr. Benjamin B. Lawrence, treasurer, No. 60 Wall Street, New York City. The committee is especially desirous that there be a large number of small subscriptions so that the matter may be a really popular tribute to one who was the personal friend of mining engineers and geologists around the world, and the benefactor of his profession for all time.

WASTE of experience is the problem which should call for the greatest efforts of conservationists and 'efficiency engineers.' Numberless cases could be cited where companies have wasted much time and more money in experiments that had previously been carefully performed in some unrelated line of work. Less striking, but amounting to a greater loss in the aggregate sum, is the daily waste of effort in a large company in securing information that is actually readily available. One man may spend some time in a hunt for data that another could produce on the instant if he were aware of the need for it. Some companies have solved this problem by establishing a clearing house for information in the form of a library, the librarian in charge being a technically trained man, and at a recent meeting of the Special Libraries Association, Mr. F. N. Morton described in some detail this work as carried on at the library of the United Gas Improvement Company. Recent lines of growth in the mining industry have tended toward the formation of the larger aggregations of capital that permit the carrying out of such refinements of practice, and the example set will repay consideration.

NEW YORK CITY has many notable features, and not the least of them are the engineering problems that arise in the corporate life of so large a municipality. The securing of an adequate water-supply gives rise to many, and, for example, the geologic engineering work performed by Mr. James F. Kemp and his associates to secure a safe crossing of the Hudson river by the new aqueduct is already well known. At a recent meeting of the Society of Municipal Engineers Mr. F. S. Cook described the heaving and fracturing of large areas of solid gneiss at Croton Falls when stripped and exposed to the sun's rays, ascribing the phenomenon to the expansion due to the rise in temperature. Mining engineers are familiar with the swelling and splitting of shales when exposed to the air in underground excavations, and quarrymen are equally familiar with a similar phenomenon, after the superincumbent layers have been removed, in deep quarries where the rocks are under enormous lateral pressure. The splitting of rocks at night, due to temperature changes, is a familiar phenomenon to every miner who has 'slept out' in the mountains, but a civil engineer may well be surprised when the solid rock at the botton of an excavation bulges up over a quarter acre of the exposed surface.

THERE is a well known story of a prisoner who, upon relating to his attorney the circumstances of his incarceration, was told: “They can't put you in jail for that,” and who replied, “Maybe they can't, but they did.” The question whether the United States Government can successfully run a coal mine is interesting, but academic. Maybe it can't, but it does. In fact, it already runs two coal mines, aside from those opened in the Philippine Islands by the United States Army. Near Pittsburg, Pennsylvania, the Bureau of Mines now operates a mine. This was primarily opened in order that the Bureau might make large-scale tests of safety explosives, of ventilation systems, electrical equipment, and conduct other technological investigations. Incidentally, however, the Government mines coal on a royalty basis and sells it through one of the large Pittsburg coal companies. Even more to the point is the mine at Williston, North Dakota, opened by the Reclamation Service. In this case, no questions of testing or studying mining conditions enter into the matter. Like the portland cement plant built by the same service in Arizona, it is purely a business project. The Reclamation engineers needed fuel at a pumping station, and, lignite outcropping abundantly nearby, they did just what a private concern would have done—opened a mine. It has now been in operation some years, to the entire satisfaction of every one concerned. An ounce of fact is worth more than a pound of theory.

AT Seattle there glimmers an *ignis fatuus* entitled 'The Modern Aladdin's Lamp Called 'Mining',' published fortnightly by Prentice & Co. It bears the motto 'We are nettled by the simplicity of truth,' and after reading the issue of September 18 we are convinced that though the editor may be only nettled, the reader will assuredly be stung. Since it is announced that no advertising is accepted, the description of a method of preventing the advance of old age by the use of certain books and medicines, as well as a 'write-up' of the Mt. Baker Gold, Copper & Tin Company, which, like an afterthought, is slipped in at the bottom of the last page, are doubtless inserted merely from an altruistic regard for the needs of humanity, and the better to serve these needs a subscription blank for the shares of the Mt. Baker company is enclosed with each issue. To quote further:

> "*The activity* of our minds is accelerated—rapidly WHEN *a bucket of cold water is dashed suddenly in our faces. We are also moved to higher animation through observation of the vigor, virility and vitality that springs suddenly and full-grown from the copulation of connected but fertile facts, which roughly rouses and wakens us up like a clap of midnight thunder; or, gently works us up to a point of acute attention, like children that see a prestidigitator produce through ledgerdemain and seemingly from nowhere, a glass bowl filled with water in which swim, live fish—which is the reason for writing this stuff, since—*
>
> Truth and facts *are often more strange than fiction.*"

The kind that emanate from Prentice & Co. undoubtedly are.

Technical Journalism and ——?

Our excitable contemporary at Salt Lake City, *Mines and Methods*, discharged a broadside last week at *The Mining Magazine* and the *Mining and Scientific Press*. The editorial in question is principally interesting as illustrating a peculiar point of view as to the functions of a technical paper. *Mines and Methods* seems quite unable to believe that a technical journal can praise technical work without having some ulterior purpose, such as raising or depressing the price of stocks. To our way of thinking, a technical paper should not be concerned with the manipulation of the stock market. As a matter of fact, no member of the staff of the *Mining and Scientific Press* owns a single share of mining stock, nor does any member have any financial interest in the rise or fall of the market. We are interested, as are all mining men, in seeing capital flow abundantly into legitimate mining investments. We do not consider it part of our function either to 'boost' or 'knock' any mining enterprise so long as it is conducted legitimately. We have not hesitated to state the exact facts, when procurable, about illegitimate stock-selling companies where the result of a promotion campaign was certain to be disastrous to the investors and to the mining industry. Our stand for honest mining is so well known that it needs no exposition. We usually have on hand the threat of at least one libel suit and have become so accustomed to it that we should not feel sure we were hitting the sore spots if we did not hear an occasional shriek. Among legitimate enterprises, however, we do not feel that it is the function of a technical journal to discriminate, and we believe that its columns can be put to much better use than in a systematic campaign either to raise or depress the price of a particular security. Evidently *Mines and Methods* thinks differently. No attentive reader of that interesting journal can doubt that one of its main purposes has been from the first to discredit the Utah Copper Company and its affiliated enterprises. That, of course, is its privilege, but when a publication adopts such an attitude it places itself in the category of brokers' circulars rather than of technical journals. This is said with no intention whatever to disparage the literature sent out by the brokers. Much of it is excellent and is prepared by thoroughly competent engineers. Such publications as Thompson, Towle & Company's *News Letter*, Hayden, Stone & Company's weekly letter, and Walker's *Copper Letter* so roundly berated by *Mines and Methods*, contain large amounts of first-class technical information. They are, however, *ex parte*, but this does no harm so long as it is understood by their readers. No matter how much excellent technical material any paper may print, when it engages in a market campaign it is a market letter. That a lawyer should defend his client vigorously is taken for granted, and we think nothing the less of him for so doing. We do not expect a lawyer's brief to be an impartial statement of fact, but that is exactly what is expected of a technical journal.

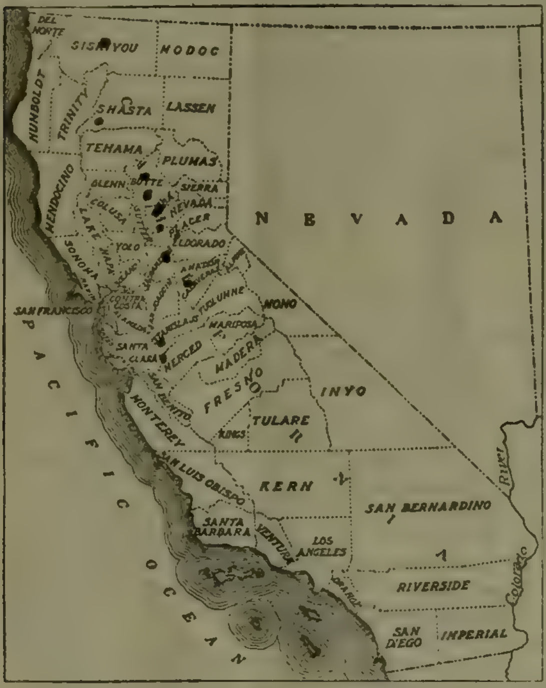
The Mining Magazine, in the paragraphs which so roused the ire of the Salt Lake paper, stated in substance that the otherwise excellent technical articles written for *Mines and Methods* by Mr. Claude T. Rice lost something of their value by evident prejudice against a particular group of properties and operating officials. This we think sound criticism abundantly justified by the facts. Readers of the *Mining Age*, published in New York, cannot fail to have been impressed with the cleverness and ability exhibited by that defender of Mr. George Graham Rice and his schemes. No one, however, looked to it for other than a partial statement. Market letters and market papers serve a useful function. They are of necessity interesting, and we welcome them all, but we vigorously protest against the assumption that a market paper is a technical journal, and we further protest against the imputation that good words for one enterprise or criticism of another in the *Mining and Scientific Press* can be bought. A publisher who has that attitude of mind is suffering from myopia.

In digging up and republishing the history of the Stratton's Independence affair, *Mines and Methods* has been misled as to matters of fact and makes insinuations that are so far from warranted as not to be excusable on the basis of mere misinformation. Such things are the accustomed, if not the legitimate, weapons of offense of a certain type of attorney and broker. The facts in the case were fully published at the time and are thoroughly understood among engineers and mining men. Mr. T. A. Rickard's professional career needs no defense. It was one of distinguished service and won for him the merited esteem of his professional associates. Criticism and innuendo by *Mines and Methods* can not affect his standing. While we do not approve of *Mines and Methods*, any more than that journal approves of us, we consider it the ablest publication of its class and one distinctly worth while. Everyone interested in the price of copper shares should read it, but he should remember while doing so that he is getting but half the story and be on his guard.

Present Day Problems in California Gold Dredging

By Charles Janin

*The first successful bucket-elevator dredge to operate in California was put in commission at Oroville in March 1898. There had been numerous previous attempts at dredging, but none of the earlier boats proved a success. The gold miners in California early conceived the idea of a machine to dig gravel from the beds and bars of auriferous streams that were inaccessible by the methods then employed, and it was only a few months after the discovery of gold in California that such a machine was shipped around Cape Horn from New York to San Francisco. This was, however, but the forerunner of many failures in gold dredging, and was soon at the bottom of the Sacramento river. During succeeding years many other unsuccessful attempts were made, and it was not until 1897 that a dredge of the single-lift bucket-elevator type was floated on the Yuba river. This dredge was built by the Risdon Iron Works for R. H. Postlethwaite, and would probably have been a success if it had been operated on some of the rich Oroville ground instead of in a turbulent stream where the dredge was wrecked during a flood, and was not repaired.



GOLD DREDGING AREAS IN CALIFORNIA.

It is not my intention to narrate in detail the history of the early failures in gold dredging, and the various steps in the development of the modern boat, but merely to touch upon this in a general way, and to call attention to the wide difference in capacity and operating cost between the first successful dredge with an actual capacity of 600 cu. yd. per day—though its rated capacity was in excess of this—and the present modern dredge with 15-cu. ft. buckets, and an average capacity of 250,000 cu. yd. per month. Even this enormous capacity has several times been exceeded on monthly runs. The first successful dredges in California were equipped with open-connected buckets, were operated on headlines, and had short-tray tailing stackers. For a number of years dredges of this type were used with varying success, generally on shallow and easily dug gravel. When attempts were made to work deeper ground and cemented gravel had to be handled it was found that these first boats were too light and it was necessary to install heavier machinery to withstand the increased strain.

The modern California type dredge with close-connected buckets, spuds, and belt-conveyor for stacking tailing was a gradual development through years of experimenting. This dredge embodies the ideas of successful operators and it is generally conceded that dredge construction and operating methods in California are far ahead of those in any other country in the world. The dredges built in California cost from $25,000 to $265,000 each; a standard 8½-cu. ft. boat costing from $150,000 to $175,000 according to conditions to be met in operation. With great improvements made in dredge construction, and corresponding reduction in operating costs, areas that were at first considered too low grade to be equipped with a dredge, are being profitably worked and the gold production from this source according to the United States Geological Survey reports increased from $18,847 in 1898 to $7,550,254 in 1910, being 28.3% of the total gold production of the State from all sources for the last year and 84.9% of the total placer gold for the year. The production for dredging during 1911 is estimated as closely as can be figured at this date at $8,000,000. The following table shows the production by years of gold won from dredging operations in California from 1898 to 1911, being a total of over $40,000,000.

Year.	Amount.	Year.	Amount.
1898	$18,847	1905	$3,276,141
1899	133,812	1906	5,098,354
1900	200,369	1907	5,065,437
1901	471,934	1908	6,536,089
1902	801,295	1909	7,382,950
1903	1,488,556	1910	7,550,254
1904	2,187,038	1911*.........	8,000,000

*Estimated.

California dredges vary in size from 3½ to 15 cu. ft. buckets. In Alaska some dredges are equipped with buckets as small as 1¼ cu. ft. to dig shallow ground, and are reported to be working profitably. A 15-ft. Marion dredge has recently been installed on the Boyle concession in Yukon Territory. The successful operation of this boat will no doubt encourage and be followed by further installations of the larger sized boats where conditions warrant in the Far North. While electricity is the ideal power for operating dredges, steam has been successfully used on a number of installations and experience has proved the merits of the gasoline and distillate engine for this work. There seems little doubt but that the successful development of the gas producer for the generating of electric power will prove an important factor in considering future dredging of gravel areas in districts where electric power or water-power for the installation of hydro-electric plants is not at present available. While it is unnecessary to go into the details of dredge construction in this article, a short description of one of the modern dredges may be profitably given here. A fuller description of a dredge of this character may be seen in the *Mining and Scientific Press* of October 7, and a complete record of dredges constructed in California in Bulletin No. 57, 'Gold Dredging in California,' issued by the State Mining Bureau and written by W. B. Winston and Charles Janin.

Yuba No. 13, one of the largest gold dredges operating in California, was put in commission at Hammonton, in Yuba River basin, August 10, 1911. This dredge was built by the Yuba Construction Co. and is one of five practically similar dredges built by the same company this year. It required 820,000 ft. of lumber for the hull and housing the hull; its dimensions are 150 by 58.5 by 12.5 ft., with an overhang of 3 ft. on each side, making 68½ ft. total width of housing. The digging ladder is of plate girder construction and designed to dig 65 ft. below water level and is equipped with ninety 15-cu. ft. buckets arranged in a close-connected line. The entire weight of the digging ladder and bucket line is approximately 700,000 lb. The washing screen is of the revolving type, roller-driven, and is 9 ft. diam. by 50½ ft. long and weighs 111,721 lb. Two steel spuds are used, each weighing over 44 tons. The ladder hoist winch has a double drum, and weighs 67,016 lb. The swinging winch consists of 8 drums, and weighs 34,193 lb. The stacker hoist winch weighs 3732 lb. The gold-saving tables are of the double bank type and have an approximate riffle area of 8000 sq. ft. The tailing sluices at the stern can be arranged to discharge the sand from the tables either close to the dredge or at some distance behind. The conveyor stacker belt is 42 in. wide and 275 ft. long, on a stacker ladder of the lattice girder type, 142 ft. long. Nine motors are in use on the dredge, with a total rated capacity of 1072 hp. The total weight of hull and equipment is 4,640,862 pounds.

---

*Presented jointly with Francis J. Dennis at the San Francisco Meeting of the Amer. Inst. of Mining Engineers.

Natoma No. 10 dredge, now under construction, is equipped with 15-cu. ft. buckets, and will have a steel hull, being the first dredge operating on a steel hull in California. The hull will be 150 by 56 by 10½ ft. and will have a total weight of 920,000 lb. This will be about one-half the weight of a wooden hull to carry the same machinery, and the draft of the boat will be considerably lighter. This boat will be in operation in April 1912.

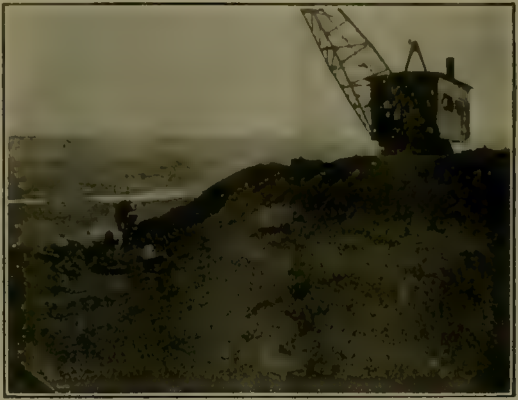
YUBA DREDGE NO. 13.

Owing to the financial success of gold dredging most of the gravel areas of California have been explored. It is hardly to be expected that any new fields as rich as those now being worked will be found, but it is possible that areas considered unprofitable for dredging, even within recent years, will be worked in the future.

The following table gives in a general way the approximate extent of dredging ground in the best known dredging districts in California, the average depth of gravel and the value per cubic yard. Much of this ground has already been dredged, and some areas of lower grade gravels which ultimately may be dredged are not included.

Counties.	Total proved dredging ground, acres.	Av. depth of ground, feet.	Av. value per cu. yd., cents.
Butte	6,600	30	15
Yuba	3,600	65	15
Placer	4,300	38	8
Sacramento	6,000	35	11
Calaveras	850	18	14
Stanislaus	200	22	14
Merced	400	20	13
Shasta	600	22	11
Siskiyou	350	35	14
Trinity	600	25	15

In addition to the lower grade gravel being worked in the future, areas considered too small for the profitable installation of an expensive modern dredge will be equipped with strong, lighter designed, and less expensive boats, and also with rebuilt dredges using machinery from dredges which have worked out the areas for which they were built, or that have been dismantled and replaced by larger boats. The machinery of some of these dismantled, and to be dismantled, dredges is in good condition, fit for many years of working life, and can be refitted on a new hull on nearby property or properties not too difficult of access, and a practically new dredge built in some cases, at less than 50%, of the cost of the original boat. It must be recognized that these rebuilt boats may not always be adapted to handle the gravel with as low operating costs as might otherwise be attained, but the smaller expense of installation will prove a large factor in their selection and use. Dredges that were first constructed in Colorado, but proved unprofitable, were dismantled and their machinery used on hulls in California. The machinery from several California dredges has been moved to other fields, and, in some cases, to Alaska. Recent examples which may be mentioned are the Scott river dredge, formerly at Callahan, Siskiyou county, where it was unprofitable, was dismantled, and the machinery has been moved to Trinity Center, Trinity county. The Butte dredge, having worked out the company's holdings at Oroville, was also dismantled and the machinery is being placed on a new hull near Jenny Lind, Calaveras county. The Scott river dredge was put in commission in August 1908, and was equipped with 7½-cu. ft. buckets. It was not quite two years in operation, being shut down May 30, 1910. It was purchased by the Alta Bert Gold Dredging Co., acting on the advice of H. G. Peake, and was moved to its ground in Trinity county. Estimated cost of building a new hull, installing the machinery on same, including a 28-mile haul, with a freight cost of over 1c. per pound, and building a power transmission line of five miles, is $80,000. The Butte dredge was put in operation during November 1902 and dismantled in July 1910. It was equipped with 3½-cu. ft. buckets. The machinery is being placed on a new hull, and includes a new bucket-line of 4-cu. ft. buckets. The cost of the installation, including the new bucket-line, has been estimated at $30,000. The figures given for moving both of these boats must be considered approximations only, as they are not official.



BUCKET SCRAPER AT WORK.

There also seems to be a field in California and elsewhere for the installation of the bucket scraper on auriferous areas too small or otherwise unsuitable for dredges, but of sufficient gold content to be profitably handled by the scraper. This method of handling gravel is profitably in use in Siberia, in the Kolchan mines at the present time, a plant having been installed by C. W. Purington. In California one has been in successful operation near San Andreas. This machine rests upon rollers by which it is moved on a plank track. It delivers to a set of trommels and gold-saving tables similar to those on a dredge. It has a 60-ft. boom upon which the scraper bucket, weighing 1½ tons and having a capacity of 1½ cu. yd., works. The bucket is raised and lowered by means of a cable working over a sheave at the end of the boom, and is loaded by means of a drag-line traveling between sheaves in front of the floor plate. Dumping is accomplished by means of an equalizing cable attached to the drag-line and on the front of the bucket, which passes over a sheave fastened to the bucket bale. The excavator is turned by a single-drum winding engine, having two cables attached, whereby a complete circle can be made and the scraper bucket operated on all sides. The machine is operated by steam power, wood being used as a fuel. Thus equipped it has excavated gravel to a depth of 35 ft., and, it is claimed, can be worked to a depth of 50 feet.

The material is dumped by the bucket into a hopper 12 by 12 ft., which feeds a trommel screen $4\frac{1}{2}$ by 22 ft., the upper part of which has $\frac{3}{8}$-in. perforations, and the perforations of the lower 18 in. being $\frac{3}{4}$ in. The oversize discharges to a belt-conveyor stacker, the undersize passes over Hungarian riffles, and then to a riffled sluice-box in which quicksilver is deposited, and finally to a 20-ft. sluice-way in which cocoa matting is used. Water is pumped into the hopper to wash the material through the cylinder. The cylinder and stacker are operated by a 15-hp. electric motor, and the whole washing apparatus is mounted on rails. It requires two men on the excavator and one on the washer. Accurate figures of operating costs are not at present available, but are understood to approximate 15c. per cubic yard. At the Kolchan mines it is claimed that exclusive of management charges, which are high, the cost of washing 24,400 cu. yd. for July was 14c. per cubic yard. While these machines cannot be compared with modern dredges in capacity and operating costs, it is claimed by those familiar with the operation, that there is a good field under suitable conditions for their use in places where it is impracticable to install dredges.

The dipper dredge has been successfully operated on small areas at Oroville and elsewhere, but does not meet with approval among dredge operators in general, who contend that the efficiency of these boats, both as to yardage and gold-saving capacity, is not up to that of the standard type. These boats have a low first cost (about $25,000 f.o.b. factory) and are built with buckets from $1\frac{1}{4}$ to $2\frac{1}{2}$ cu. yd. capacity. It is claimed by the dealers and some operators that under the following conditions there is a field for this type of dredge: (1) where the ground is somewhat shallow; (2) where the extent of the ground is not sufficient to warrant the installation of a costly dredge; (3) where the material is of a rough character, boulders, and stumps; (4) where the ground is mixed with more or less clay, as the dipper will clear itself notwithstanding the adhesiveness of the material.

The reported successful operation of a small Risdon dredge on the middle fork of the American river near Loomis, Placer county, under conditions thought by many to be impossible for operation, will undoubtedly encourage other installations in rivers at times torrential. A. A. Tregidgo is now promoting a company for the dredging of gravel some distance below this place. Without attempting to pass on the merits of either of these undertakings, it is interesting to consider them as engineering problems, and their success will draw considerable attention to similar gravel areas in this State and elsewhere. While gold dredging in California has been mainly confined to gravel areas some distance from the main river channels, it is claimed that a small boat, with some modifications in the hull to suit the river conditions, and adapted for work in a swift current with head-line and mooring winches of greatly increased strength, can be profitably operated, even in the winter months, in the California rivers where not in conflict with the present débris laws. In addition to the use of a small dredge, it is proposed by Mr. Tregidgo to operate a hydraulic elevator on the same property, water being available at a head of 1000 ft. This water will first be used at a head of 400 ft. to generate electric power to be transmitted to the dredge. From this point the water will have a head of 600 ft., to be used in the hydraulic elevator. In addition to these enterprises, there are several proposed dredge installations on somewhat similar areas in this State, concerning which definite information is not available at present.

The suction dredge has never been favorably considered in gold dredging, except by the inventors and builders. It is claimed by those interested that one is in successful operation in Shasta county, and another in Siskiyou county, though other information is to the effect that these boats were not a financial success and are no longer operating.

A method closely allied to dredging, which may be termed a hybrid of dredge and hydraulic mining, is attracting much attention in this State. This is the Tarr Mining Co.'s plant at Smartsville, California, which was built to operate the Old Blue Gravel hydraulic mine. This mine was a producer in early days, but was shut down by the Débris Commission. It is believed that the Tarr company will be able to operate in compliance with the present law. From an engineering standpoint, the proposal has some interesting features. Briefly, it consists of hydraulicking the gravel bank to a sump in front of a stationary dredge building of concrete and sheet iron, where a regular steel girder dredge ladder, equipped with fifty-two 7-cu. ft. buckets elevates the gravel to a trommel 45 by 6 ft. with $\frac{1}{2}$-in. holes. From the screen the undersize flows to gold-saving tables with Hungarian riffles having an approximate area of 4000 sq. ft. The oversize passes to a belt-conveyor 570 ft. long, built in two sections, each section being driven by a 50-hp. motor. A 100-hp. motor is used on the digging ladder, and a 30-hp. motor on the revolving screen. At the end of the belt-conveyor stacker two Bleichert tramways are being constructed. These will afford a much larger dumping ground for the tailing.

The fine material, after passing over the gold-saving tables, flows through a bedrock tunnel about $\frac{1}{2}$ mile long and is elevated to a concentrating plant equipped with tables of the Overstrom type. The material first passes through revolving screens, the oversize being carried outside the concentrator, and the undersize to the tables. It is the idea of the management that this plant will save black sand, which is claimed to be valuable, and any gold and platinum that escapes the first tables.

The concentrator stands several hundred feet from the Yuba river, and a concrete dam will be constructed to afford a settling basin for the tailing. This experiment will be watched with interest. Its success will undoubtedly mean that other properties formerly worked as hydraulic mines, which have been shut down by the Anti-Débris Commission, will be operated on somewhat similar lines. The equipment of such a property is no small matter. The operating cost as yet is purely speculative. The management of the Tarr company does not believe that the cost of operating the plant will exceed 8c. per cubic yard.

On Bonanza creek, in the Yukon, a portable bucket elevator arranged to elevate gold-bearing gravel to a system of portable sluices, the position of which can be changed when necessary to obtain a new dump, has been in more or less successful operation by the Yukon Gold Co. for a number of years, but only one attempt, so far as is known, has been made to adjust this method to California gravels. The mode of operation is as follows: A sump of approximately 20 ft. square with a depth of 14 to 16 ft. below bedrock is excavated to receive the lower end of the elevator. A channel or bedrock sluice emptying into the sump with a grade of 5 in. to 12 ft. is excavated in the bedrock and provided with riffles. The gravel bank to be treated is hydraulicked with two 3-in. giants, and a third giant sluices the gravel to the sump from which the buckets elevate it to a riffled sluice about 25 ft. high. The elevator ladder is equipped with buckets of 3-cu. ft. capacity, close-connected and driven by a 50-hp. motor. The water used in the upper sluice is pumped from the sump by one 12-in. centrifugal pump belted to a 100-hp. motor, and one 8-in. pump driven by a 50-hp. motor. A derrick with a long boom is placed in a position convenient for handling any large boulders. Records of operating cost have not been made public by the Yukon Gold Co., and it is understood that the use of these machines will be discontinued or considerable changes made in the method of operating them.

A somewhat similar machine was operated a few months during 1910 at Poker Bar, Trinity county. This was installed by R. E. Whitcomb, at a cost of approximately $15,000. The motive power was steam, wood being used as fuel. The expenses of operation were great, but no accurate data are obtainable at present. It is said that the operation of the machinery thoroughly demonstrated the value of the gravel area, and it is reported that a dredge will be installed this year. The management contemplates moving a Marion dipper dredge, formerly successfully operated at Oroville, and which had turned over the holdings of the original company. It is estimated that this dredge can be put in operation at a cost of $15,000. At the present time there are 62 bucket elevator dredges operating in California, and five under construction. Of the six dredges put in commission in 1911, four have been built by the Yuba Construction Co. and are equipped with 15-cu. ft. buckets, one was built by the Union Iron Works and equipped with $8\frac{1}{2}$-cu. ft. buckets, and one by the Risdon Iron Works with 4-cu. ft. buckets. One of those under construction has buckets of 15-cu. ft. capacity, one $7\frac{1}{2}$-ft. buckets, one 7-ft., one 5-ft., and one 4-cu. ft. buckets.

It is interesting to note that of the 62 dredges which are operated by 28 companies, 30 are operated by three companies controlled by W. P. Hammon and associates, distributed among three counties, as follows: Butte county, 8; Yuba county, 13; Sacramento county, 9. It may here be mentioned that the great progress and improvement is due in a great measure to the enterprise and successful operations of Mr. Hammon and his associates. Couch dredge No. 1, the first successful bucket-elevator dredge put in commission in the State, was financed by Mr. Hammon and the late Thomas Couch, and it seems eminently fitting that Mr. Hammon should be the leading gold dredging operator in California, and in control of the largest dredging companies in America.

What seems to be a record in dredge construction and worthy of mention is the building of the dredge for the Julian Gold Mining & Dredging Co. on Osborn creek, near Nome, Alaska. This dredge was constructed by the Union Construction Co. of San Francisco. The dredge was shipped from San Francisco on June 1, arriving at Nome June 13. On June 17 they commenced hauling material, and on July 22 the dredge was completed and operations started. The dredge hull is 30 by 60 by $6\frac{1}{2}$ ft. It is equipped with 34 open-connected $2\frac{3}{4}$-cu. ft. buckets, and is designed to dig 14 ft. below water-level. Power is furnished by gasoline engines as follows: one 50-hp. for digging ladder, winches, and screen; one 30-hp. for pump; one 7-hp. for lighting apparatus; a total of 87 hp. Distillate costs at Nome 21c. per gallon. Operating expenses at present range from $110 to $125 per day, and the capacity of the dredge is from 1000 to 1300 cu. yd. per day, indicating an operating cost of from 10 to 11c. per cu. yd., exclusive of repairs. The cost of the dredge complete and in operation was $45,000. The Union Construction Co. also built a similar dredge for dredging tin, near Cape York, this latter being the first tin-dredging operation to be carried on in America. Its future will be watched with interest and may be followed by further installations.

With the development of the gold dredge to its present efficiency, the question is often raised as to when the limit in size for economic dredge installation will be reached. Much depends upon the conditions met in operation. There is no question as to the mechanical possibility of larger buckets. In Boston harbor a bucket-elevator dredge equipped with buckets of 2-cu. yd. capacity has been successfully operating for some years on harbor work, and on the Danube river in Germany a bucket-elevator dredge having $2\frac{1}{2}$-cu. yd. buckets is now in operation. While the mechanical possibilities have thus been proved, to apply such radical changes in size to the gold dredge of today would necessitate an entirely different arrangement of the gold-saving tables and would probably result in a general modification of the whole gravel-washing apparatus now in use. Even the most optimistic advocates for increasing the size of the dredge buckets would hesitate at recommending a 2-cu. yd. bucket, which is nearly four times the present size of the buckets on the largest gold dredges in operation, but there are a number of engineers who believe that the bucket-elevator dredge with buckets having a capacity of 1 cu. yd. will be constructed before long. While a dredge of this character would necessarily be equipped with heavier machinery and a larger hull than those on the present 15-cu. ft. boats, it is, as before stated, quite possible that, with modifications of the washing apparatus, the hull of the 1-cu. yd. dredge may not be proportionately larger. The present 15-cu. ft. boats have a hull 60 by 150 by $12\frac{1}{2}$ ft., with a deck overhang of 5 ft. on either side, making a total width of 70 ft. The gold-saving tables are double-bank type and have an approximate area of 7000 to 8000 sq. ft. Without some change in the washing apparatus, it can readily be seen that 14,000 sq. ft. of table area would either necessitate a hull of greatly increased size, or additional tiers of tables for which an increased length of bucket ladder would be required to elevate the gravel to the additional height, or a general change in the design of the boat.

TARR GOLD-WASHING PLANT.

There may be a field for dredges of this size, for instance, in the Oroville and Folsom fields, to re-dredge the tailing piles left from the first dredging operations. After many of the cobbles have been removed for the rock-crushing plants, the ground, if dredged, will, in many cases, yield a fair return. Especially would this be the case in the areas where the early dredges worked, as the gold-saving apparatus of the first successful dredges was not as efficient as those in present use.

In addition to the gold recovered from the gravel, the reclaiming of the land for agricultural purposes might be a considerable factor in estimating the total profit to be won from the installation of a mammoth dredge for this class of work. The first dredges, in turning over the ground, necessarily deposit the top soil on the bottom, and the gravel and boulders from the tailing-stacker on top of this. After much of the coarser gravel is removed for rock-crushing operations, with some such arrangement as that which is being tried out in New Zealand in resoiling experiments, this soil now below the gravel could, in re-dredging, to a great extent be deposited on the top of the coarser material. In reclaiming the dredged land it is, no doubt, a matter worthy of consideration. Any estimate of the operating cost of a dredge of this character is, of course, pure speculation, but there seems every reason to expect that, under favorable conditions, or in re-dredging some of these previously dredged areas, a very low operating cost would be obtained.

The operating cost of dredging is always a matter of interest, but working costs cannot be fairly used in comparison, unless uniform methods of determining them are employed, and also unless operating conditions are somewhat similar. As in other branches of the mining industry, it may also be said that the apparent operating cost is in a great measure a matter of bookkeeping. As the time available for preparing this article was limited, it has been found impossible to prepare new data on working costs of dredges in California, so I have utilized a table prepared last year by me and published in the *Mining and Scientific Press* of July 30, 1910. Under similar conditions, the operating costs are practically the same. The new boats have not been working long enough to make any figures of operating cost of much value, but it is understood that they will under the same conditions appreciably lower the costs obtained by the 13½-ft. boat.

It is interesting to note the following average operating cost per cubic yard of the large companies working in California during 1910: The Yuba Construction Co., for the year ended February 28, 1911, handled 13,970,728 cu. yd. at a total cost of 5.67c. per cubic yard. The Natomas Consolidated handled, for the year ended December 31, 1910, 15,989,525 cu. yd. at a total cost of 4.52c. per cubic yard, and during the six months ended June 30, 1911, 10,793,891 cu. yd. at a total operating cost of 3.77c. per cubic yard. This company has put in commission during this year three dredges with buckets having a capacity of 15 cu. ft., one being in the Feather river division at Thermalito, and two in the Folsom division on Rebel hill. These two boats are now satisfactorily handling ground that for a long time was considered too difficult for economical dredging. The gravel is deeper and more compact than any other in the district, and dredge No. 8 is handling ground containing much stiff clay. The Oroville Dredging, Ltd., for the year ended July 31, 1910, handled 5,661,612 cu. yd. at a total cost of 5.05c. per cubic yard.

Montana Metal Production, 1910

The value of the mine output of gold, silver, copper, lead, and zinc in Montana in 1910, according to V. C. Heikes, of the U. S. Geological Survey, was $48,358,253, against $51,429,694 in 1909, a decrease of $3,071,440, occasioned almost entirely by the lessened output of copper ores. The value of the gold, silver, and copper combined was $4,326,868 less than in 1909, while the value of the lead and zinc yield was $1,255,427 more than in 1909. The value of the production of Silverbow county, which includes the Butte district, was 91% of the total value of the metals from Montana. The decrease in value in this county was $3,108,861, so that the combined production of the other counties in Montana was slightly greater in 1910 than in 1909.

The production of gold in 1910 was only $61,024 less than in 1909. The greater part of the gold, 115,261.06 oz., or 64% of the total, was from silicious ores; and 31,441.93 oz., or 17%, came from copper ores. The placer gold in 1910 amounted to $575,917, of which $473,385 was obtained by dredging. The gold won from placers was $32,545 greater than in 1909, but that taken from lode mines was $93,569 less.

The production of silver in Montana in 1910 was 12,162,857 oz., against 12,378,714 oz. in 1909. Nevada now takes the leading place in silver output in the United States, which Montana held in the years 1909 and 1908. Of Montana's 1910 output of silver, 9,153,590 oz., or 75%, came from copper ores, and 2,139,465 oz., or 17.6%, from silicious ores. Bullion at gold and silver mills produced only 130,900 oz., while concentrate produced 8,208,644 oz., and crude ore shipped to smelters contained 3,766,375 oz. Silverbow county produced 10,400,840 oz., or 85.5% of the State's production, compared with an output of 10,609,328 oz. in 1909.

The production of copper in Montana decreased from 312,058,011 lb. in 1909 to 284,808,553 lb. in 1910, a loss of 22,278,460 lb. The Summit Valley or Butte district contributed all but 581,648 lb. of the total.

The production of lead in Montana increased from 2,983,430 lb. in 1909 to 4,106,292 lb. in 1910. Nearly all the metal-mining counties in Montana made a small yield of lead, but Jefferson county, with a production of 1,975,492 lb. in 1910, against 1,568,696 lb. in 1909, produced nearly half of the output for the whole State of Montana during both years.

Of Montana's zinc output in 1910, which was 31,638,184 lb. (figured as spelter), against 9,359,724 lb. in 1909, the Summit Valley district, in Silverbow county, produced all but 18,000 lb. Nearly all of the zinc ore was sent to concentrating plants, and the concentrate produced contained 31,334,204 lb. of zinc; the crude ore sent to smelters yielded only 303,980 pounds. It will be seen that Montana is rapidly becoming an important zinc producer.

The number of deep mines producing metals in Montana in 1910 was 423, against 448 in 1909, and the number of producing placer mines was 157, against 170. The average total recoverable value per ton of ore produced increased from $9.39 in 1909 to $9.41 in 1910.

MINE PRODUCTION OF GOLD, SILVER, COPPER, LEAD, AND ZINC IN MONTANA IN 1910, BY COUNTIES.

Counties.	Ore treated, Tons.	Gold.*	Silver,* Fine ounces.	Copper, Pounds.	Lead, Pounds.	Zinc, Pounds.	Total value.

*Includes placer production.

Examination of Dredging Properties

By Francis J. Dennis

*Many factors govern the value of dredging ground, and much capital can be wasted by the mistaken policy of contracting for the purchase of property and the installation of machinery before a thorough examination has been made. To the uninitiated investor the presence of gold is generally the criterion, and very superficial evidence is necessary to satisfy him as to this point. He considers the comprehensive report of a competent engineer as a wasteful extravagance and cannot understand why the engineer requires so much time and money to ascertain the information on which to base his conclusions when the promoter can furnish him such pleasing and satisfactory data with but little expenditure of time and money. The uninitiated investor will often optimistically risk capital for purchase and equipment, and not until the venture comes to grief does he learn that the conditions are wholly unsuited for dredging. In many instances, a short preliminary examination by a competent engineer would have disclosed these facts. The mere presence of gold is by no means sufficient; some of the other factors necessary to be ascertained in determining the value of placer ground for dredging purposes are: (1) character and distribution of gold, and how much can economically be recovered; (2) character of bedding underlying the gravel, its contour, and whether its gold can be recovered by ordinary dredging operations; (3) area and depths of gravel, surface contour, overburden, water-level, proportion of fine and boulders, and the presence of any material which might interfere with dredging operations and recovery of the gold; (4) water supply, power available, labor, transportation, and supplies, and cost of these; (5) climatic conditions; (6) title to property, cost and royalties, and legal obstacles to carrying on dredging operations.

A brief reconnaissance may be sufficient to determine that some of the essential conditions for successful dredging are lacking and no further expense need be incurred. Exposures in the gullies, pits, and shafts often afford considerable evidence of the extent and characteristics of the gravel and contour and character of the bedding, and this may be readily supplemented by sinking a few additional shafts or drilling a few holes. The preliminary report proving satisfactory, arrangements should be made for thoroughly testing the ground. The area should be surveyed and the shafts or drill holes placed according to the sampling scheme adopted. Information obtained during the preliminary examination should be of use in forming this plan. Where the deposit of gravel and occurrence of gold is fairly regular throughout the area, it is generally laid out into squares of from 200 to 500 ft. Where the occurrence is in channels, this method cannot be pursued, and more judgment and ingenuity is called for in placing the holes and in making estimates from the results obtained. Holes may be placed at short distances across the channels in rows at regular intervals, and it is sometimes the practice to arrange the holes so that those of alternate transverse lines form longitudinal lines. Whether shafts shall be sunk or holes drilled is a question of expediency. Shafts afford the most complete information, and where round shafts can be cheaply sunk, this method is advisable. Where expensively timbered shafts are required and water and other features militate against shaft-sinking, the cost is prohibitive and drilling is resorted to. It is by this latter method that most of the dredging ground in California has been prospected, but it must be borne in mind that the prospectors previously had considerable information as to the characteristics of the gravel and bedding.

No. 3 Keystone drills are usually used in making drilling tests, but as the plant is heavy and somewhat difficult of transportation, the development of the hand-drill in recent years has made it an important factor in the prospecting of gravel areas in foreign countries, or in localities difficult of access where the transportation charges are high. Its low first cost—about one-half of that of a steam drill—the great reduction in weight—about one-tenth of a non-traction or one-fifteenth of a traction drill, exclusive of supplies—and the further fact that the whole hand-drill outfit, weighing a little over 1000 lb., can be made up into packs, with a maximum weight of less than 75 lb. each, is of considerable importance in prospecting. A complete and very interesting article on the Empire hand-drill for prospecting work, written by J. Power Hutchins and Norman Stines appeared in the *Mining and Scientific Press* of January 7 and 28, 1911. In new territory it is advisable, even though expensive, to sink a few shafts in the initial stages of the investigation, and the data thus obtained will enable a closer interpretation of the character of the ground passed through in drilling.

It is not intended that this article shall discuss the details of drilling and sampling operations, types of drills, and methods of determining the gold content of samples. But it should be borne in mind that reliable, experienced men should be employed in this work, and that constant vigilance should be exercised. Field and time books should be conscientiously kept, assay values at various depths noted, characteristics of the bedding and gravel, time consumed, difficulties encountered, and features that might militate against dredging recorded. These data should be recorded in the prospecting log-book, which at the finish should contain a summary of all data obtained during the progress of the drilling. From this the engineer should then allocate the results to the proper area, eliminate unprofitable areas where practicable, and summarize the yardage and value of the area that should be worked. In making this estimate there is no fixed formula for discounting the results indicated by the drilling test, but experience has shown that the amount of gold obtained by dredging is generally only from 75 to 80% of that indicated by prospecting. Having ascertained that the conditions are favorable for dredging, it is then incumbent on the engineer to determine on the type and size of dredges, number to be installed, and general campaign to be followed.

Having a given area, the yardage and contents of which can be estimated with considerable certainty, he is called upon to decide what equipment will yield the best economic results. His information of the physical characteristics of the area, together with his general knowledge of what is being accomplished in other fields, should enable him to closely estimate operating costs with dredges of various capacities and construction. A small yardage will evidently not justify a large and expensively constructed dredge, nor would the extra expense of construction necessary in a dredge for heavy ground be justified in building a dredge to work a similar yardage of lighter ground. Amortization of the cost of equipment should be set off against operating costs, and no extra expenditure be incurred that will not be justified by a corresponding reduction in operating costs. For example, assume an area of 100 acres of gravel, 11 yd. deep, and containing 5,000,000 cu. yd. A 13½-ft. boat would cost about $250,000 and would work out the area in less than two years. Assume the operating cost to be 4c. per yard, the amortization of the equipment would be 5c. per yard, making a total of 9c. per yard. A 5-ft. boat would cost about $85,000 and would work out the area in about five years. Assume the operating cost to be 6c., the amortization of the equipment would be 0.566c., a total of 6.566c. per cu. yd. The installation of the smaller capacity boat would be clearly advisable. Assume the acreage to be 300 and the yardage 15,000,000. The operating cost of the large boat would be 4c. and the amortization 1.666c., a total of 5.666c. per yard. Two

---

*A paper presented jointly with Charles Janin at the San Francisco Meeting of the Amer. Inst. of Mining Engineers.

1-ft. boats at a total cost of $170,000 would be required to handle this yardage. The operating costs would be 6c. and the amortization 1.132c., a total of 7.132c. per yard. Here the installation of the larger boat is clearly advisable. It is not thought necessary to enter into the refinements of interest calculations in the above examples, but where the operating profits are large, this factor is well worthy of consideration.

The value of the plant as an asset after the area has been exhausted should also be taken into consideration. The engineer is, of course, presumed to have taken cognizance of, and provided for the amortization of the initial investment in presenting his report to his principals. Moreover, he may have been sent to report on the area as a dredging undertaking, and, although he finds that it is not suitable for simple dredging alone, some modified form or some method which is an outgrowth of the industry may be profitably undertaken. It is incumbent upon the engineer to use the greatest care in ascertaining information about the property, and the greater his ability and experience the more valuable will his report be to his principals.

Metal Production in Oregon, 1910

In Oregon, according to Charles G. Yale, of the U. S. Geological Survey, the total value of the mine production of gold, silver, and copper in 1910 was $700,676, against $827,001 in 1909, which, however, also includes the value of the lead produced in that year. The ore treated in 1910 was 82,132 short tons, against 59,281 tons in 1909. The production of gold decreased from $781,964 in 1909 to $679,488 in 1910; that of silver increased from 27,827 oz. valued at $14,470, to 35,978 oz. valued at $19,428; that of copper fell off from 235,000 lb. valued at $30,550, to 13,861 lb. valued at $1760; and that of lead declined from 400 lb. in 1909 to nothing in 1910. Baker county led in gold production with an output of $401,002, mostly from deep mines, followed by Josephine with $150,048 from both placers and deep mines. All of the copper production and 29,835 oz. of the silver output also came from Baker county, whose output of gold, silver, and copper was valued at $418,873 in 1910. The combined gold output from southwestern Oregon in 1910 was $209,324, of which $130,103 was placer gold. The placer gold output of this region decreased $55,149 in 1910. The mines of northeastern Oregon produced $470,164 in gold in 1910, of which the placer yield was $40,822 and the deep-mine yield $429,342. The placers of this region showed an increase of $4756 in 1910 and the deep mines a decrease of $42,311.

Metal Output, New Mexico, 1910

The value of the mine production of gold, silver, copper, lead, and zinc in New Mexico in 1910, according to C. W. Henderson, of the U. S. Geological Survey, was $2,691,080, against $2,070,368 in 1909. The amount of ore treated was 191,865 tons, against 164,156 tons in 1909, and the metal production was $482,424 in gold, against $239,491 in 1909; 843,987 oz. of silver, valued at $455,753, against 397,783 oz., valued at $206,847, in 1909; 4,614,386 lb. of copper, valued at $586,027, against 5,393,146 lb., valued at $701,109; 4,320,841 lb. of lead valued at $190,117, against 5,029,767 lb. valued at $216,280; and 18,088,129 lb. of zinc, figured as spelter, valued at $976,759, against 13,085,945 lb. valued at $706,641. There were 85 deep mines producing in 1910, against 111 in 1909. Of the 1910 producers, 39 were in Grant county, 11 in Socorro county, and 9 in Luna county. The total average recoverable value of ore in New Mexico in 1910 was $13.89 per ton, against $12.48 in 1909. Socorro county led in the production of gold, silver, lead, and zinc, and Grant county (including the important Chino copper mines) led in the output of copper. The mining industry was flourishing in New Mexico in 1910, and further increased production may be looked for.

The number of deep mines producing metals in Colorado in 1910 was 856, against 904 in 1909.

Mineral Deposits of Ducktown, Tennessee

By W. H. Emmons and F. B. Laney

[*]The mineral deposits of Ducktown are situated in the southeast corner of Tennessee, near the North Carolina line, and extend southward into Georgia. The deposits were discovered in the late forties and, except during a brief interval in the early sixties and a longer one from 1877 to 1890, mining operations have been carried on continuously since their discovery. They had produced to the end of 1909 over 190,000,000 lb. of copper, about 1,500,000 tons of iron ore, and a relatively small amount of silver and gold. They yield at present, in addition to the metals, about 650 tons of sulphuric acid daily. Two companies are operating in the district, each having its own smelter, railroad, and acid plant. These are the Tennessee Copper Co., with headquarters at Copperhill, and the Ducktown Copper, Sulphur & Iron Co., with headquarters at Isabella, about 3 miles north of Copperhill. The production of copper in 1909 was 19,207,747 pounds.

The district is included in the mountainous area of the southern Appalachians, and the greater portion of it is a small intermontane plateau about 1600 ft. above sea-level, which is nearly surrounded by mountains that rise from 1000 to 2000 ft. higher. The deposits are included in an area 6 miles long and 4 miles wide, and all are on the dissected peneplain which occupies the central portion of the Ducktown basin. The outcrops are composed of iron oxides and quartz, and contrast strongly with the country rock. All the lodes have a general northeast strike. South of the Culchote mine, which is near the centre of the productive area, they strike more nearly north than east; north of the Culchote they strike more nearly east than north. In general, the lodes dip southeast, but some dip northwest. The deepest development underground is about 800 ft. below the surface. The distribution of the lodes is shown in the illustration on the next page.

In the main, the deposits are roughly tabular. Some of them are lens shaped and most of them are at places curved. All are included in metamorphosed sedimentary rocks and, except where faulting or close folding is apparent, the beds are parallel to the contacts of ore and country rock. The primary ore consists of pyrrhotite, pyrite, chalcopyrite, zincblende, bornite, specularite, magnetite, actinolite, calcite, tremolite, quartz, pyroxene, garnet, zoisite, chlorite, micas, graphite, titanite, and feldspars. The minerals are generally intergrown and of contemporaneous age. Essentially the same minerals are found in all the deposits, but they appear in varying proportions at different places in the lodes. Where the content of copper is above 1.5%, or where sulphur is high, the material is ore, but where the proportion of actinolite and other lime silicates is greater and the sulphides less abundant, the material, though containing copper and sulphur, is unworkable. Along the strike and down the dip the ore grades into this lime-silicate rock, and in some places it grades into marmarized limestone. The ore zones may be considered therefore as tabular bodies composed of ore, of lime-silicate rock, and of marble. As thus defined, these zones vary from a few feet to nearly 200 ft. in width and average probably between 50 and 75 ft. The amount of ore is about equal to that of the lime-silicate rock and marble. At some places the ore, the lime-silicate rock, and the limestones have schistosity or banding which is parallel to the boundaries of the ore zone, and wherever bedding planes have been made out in the marble and in the lime-silicate rocks these are likewise parallel to the boundaries of the ore zone and country rock. Some of the layers of sandy schist included in the ore zone are believed to represent beds that were deposited with the limestones.

The ore minerals are not arranged in layers or crusts one upon another, like the minerals deposited from solutions in an open cavity, but are intergrown and are assumed to have formed at the same time. At some places the silicates inclose the sulphides, at others the sulphides inclose the silicates, and at still others the two are intimately intergrown so that neither set of minerals may be said to inclose the other. The oxides, magnetite and specular hematite, are not abundant, but both have been recognized, and where they are developed they are intergrown with the sulphides and with the lime silicates. Where the purer limestones are recrystallized into marble the bedding is not apparent, but in the aluminous phases it is clearly shown.

---

[*] Abstract from 'Contributions to Economic Geology, 1910,' U. S. Geol. Surv. Bull. 470-C.

Veinlets of pyrrhotite and chalcopyrite cut the hornblende and zoisite in some of the ore and fill cracks along the cleavage of the silicates. At many places the sandy schists near the ore zone are heavily impregnated with iron and copper sulphides, but this material is generally not workable. Along fault zones, where drag of ore and schist have been replaced and impregnated, workable ore is locally developed.

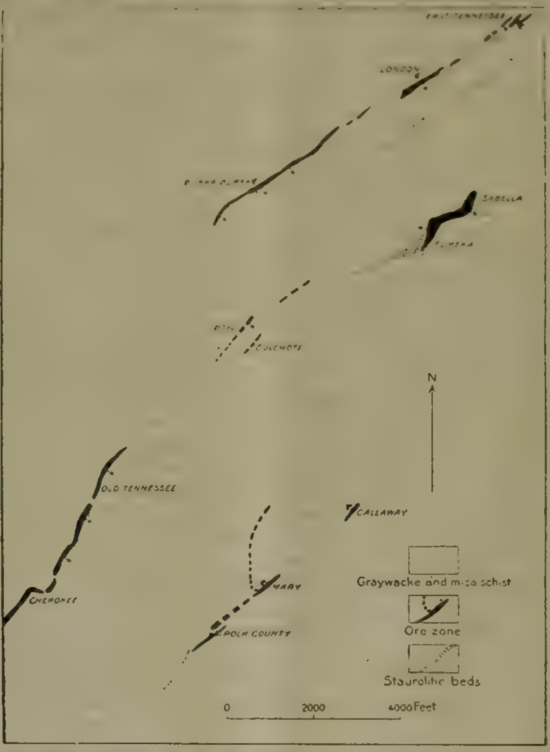
The Ducktown lodes are composed of three kinds of ore. The outcrops consist of hydrous iron oxides with smaller proportions of other minerals, chiefly kaolin and quartz. This ore extends from the surface downward to a maximum depth of about 100 ft. Below the iron ore there is generally a few feet of chalcocite ore, which in most of the deposits lies like a floor below the gossan iron ore. Below the chalcocite zone is the yellow sulphide ore which has already been described. This ore extends downward as far as exploration has gone, and is assumed to be the primary ore from which the chalocite zone and the gossan have been derived. In all the deposits now mined the chalcocite was almost completely exhausted years ago and a large portion of the gossan ores has been shipped to iron furnaces. The opportunities for studying these ores are now meagre. The workings in black ore are accessible in some of the mines, but even where the ores have not been removed, extensive changes have doubtless taken place as a result of leaching after the ground-water level was depressed by mining and pumping in levels below.

The deposits of gossan ore vary in width from a few feet, as shown in the narrow openings along the Cherokee lode, to 250 ft. in the Isabella and Eureka pits. Few of them extend downward from the surface more than 100 ft. The greatest depths are below the hilltops, and where the lodes are crossed by running streams the gossan ores are thin or lacking. The iron ore is porous and earthy. It carries from 40 to 50% of iron, and on account of its low content of phosphorus it is especially desirable for mixing with lower-grade high-phosphorus ores to bring the mixture within the bessemer limit. Silica and alumina together are generally less than 12%, although in some of the ores they are as high as 17%. Copper varies from 0.3 to 0.7 per cent.

Hydrous iron oxides are the most abundant minerals. Silica is present in varying amounts. Some of it is quartz residual from the primary ore, but a red silicious mineral resembling jasper was noted in several of the deposits. Some of this is an intimate mixture of hydrous silica and iron oxide which has formed presumably by the solution and precipitation of silica during weathering of the deposits. A small amount of kaolin is generally present. It is developed by reactions of sulphate water on the aluminous minerals of the ore and wall rock. Cuprite has been noted in the oxidized ores and it is probably the principal copper mineral. Native copper has been reported. A small amount of sulphur, less than 1%, is present. It occurs as native sulphur, in pyrite, and in sulphates.

Below the gossan iron ores is a zone of dark, rich copper ores, consisting of chalcocite and other copper minerals in a gangue of sulphates, quartz, and decomposed silicates. Under the higher portions of the outcrops of the lodes the top of this zone is about 100 ft. below the surface, but the depth decreases down the slopes, and where the lodes are crossed by running streams the secondary copper ores are exposed at the surface. The upper limit of the chalcocite zone follows the level of ground water, which, in turn, follows the contour of the country, but is less accentuated. Occurring below the chalcocite zone is the lower grade primary ore. The rich secondary copper ore is a mixture of the primary minerals and minerals that have been deposited by sulphate waters since the deposits were exposed to weathering.

Weathering and related processes operating on an ore composed of iron and copper sulphides generally result in the enrichment of a certain zone. As a rule, the top of this zone is near the water level, and it extends downward for varying distances below the water level. The waters are sulphate solutions, as shown by analyses, and in the zone above the water level, where air is admitted, acid or ferric sulphates predominate. In such solutions copper is readily dissolved. Below the water table the acid reacts with sulphides that precipitate copper sulphide from sulphate solutions. From the sulphides hydrogen sulphide is formed. The sulphuric acid is used up also by reactions with gangue minerals, some of which result in the production of calcium sulphate, alkali sulphates, and other inert salts. The solutions below the water-level are consequently less acid and probably do not dissolve copper. It is noteworthy that the solution taken 37 ft. below the water-level in the Callaway mine contains less than half the free acid in the analyses of the sample taken at the water-level. The secondary zone in the Ducktown district is less extensive vertically than most chalcocite zones elsewhere. The lodes are comparatively impervious to downward circulation, and it is believed that the reactions were brought near to completion before the descending oxidized solutions had moved downward great distances. It is thought also that the reactions precipitating copper sulphide take place more rapidly with pyrrhotite than with pyrite or chalcopyrite. Experiments planned to show the rate of solution of different minerals in acid-sulphate waters and the rate at which hydrogen sulphide is liberated by these minerals in dilute acid solutions are being made by R. C. Wells, of the Geological Survey. It is hoped that quantitative data may soon be available for the discussion of these reactions.



OUTLINE SKETCH SHOWING POSITION OF PRINCIPAL ORE DEPOSITS IN THE PRODUCING PORTION OF THE DUCKTOWN DISTRICT. THE ARROWS INDICATE THE DIP OF THE LODE.

Estimation of Calcium Oxide in Lime Used in Cyanidation

By LUTHER W. BAHNEY

[*]Lime is the alkali that is almost universally added to the solutions in the cyanide process of gold and silver extraction for maintaining the so-called protective alkalinity. It is produced by the burning of limestone. The value of lime for this purpose depends upon the percentage of calcium oxide contained, which is determined by three factors: (1) purity of the limestone used; (2) degree of the burning temperature and the period of burning; and (3) length of time of storage of burned material and the condition stored, and whether it has been damp or wet during the storage. These three factors render uncertain the quality of lime bought in the open market. In the United States, lime bought from reliable manufacturers, who thoroughly burn a pure limestone and deliver at once to the consumer from the kilns, may be of a fairly high and uniform composition; but in Mexico and Central America, where it is purchased from many small producers, who often start with a poor grade of limestone and burn it in small crude kilns with as little fuel as possible, the quality of the product is quite variable. It is therefore apparent that there is a great need for a rapid technical method for the valuation of the lime to be used in a cyanide plant.

The determination of calcium by the gravimetric method, with the necessity of determining also the proportion of CO_2, SiO_2, and Fe, requires too much time, and is usually out of the question for an isolated plant unprovided with a skilled chemist and the necessary apparatus. The calculation of all the Ca so found to CaO, although sometimes done, is manifestly inaccurate. Several methods of titration by means of a standard acid have been described, and no doubt give results sufficiently accurate for a technical method, but the objections to these methods are that they involve the preparation of a standard solution of some acid, usually decinormal hydrochloric acid, which cannot be weighed out, but must be standardized with some other standard solution. Solutions of the following acids have been used by different operators for standardization: sulphuric, nitric, hydrochloric, and oxalic. Oxalic acid is perhaps the most favorable for this purpose, because a standard solution can be prepared by weighing the solid acid and dissolving in water. The use of the solution employed to determine the alkalinity of the cyanide solutions has also been suggested. While the method of standardization with oxalic acid is open to the objection that the hydration of the acid may vary somewhat, yet it yields a solution sufficiently accurate for technical work, but so far as I am aware its use has not been suggested.

For the purpose of determining the feasibility of using oxalic acid, a solution of oxalic acid was made by dissolving 14.6068 gm. in enough distilled water to make a litre, this strength being recently suggested for determining the protective alkalinity of cyanide solutions. A decinormal solution of pure hydrochloric acid with distilled water was also made, and both were standardized with a solution of chemically-pure sodium carbonate. Pure CaO was prepared by grinding pure white crystals of calcite in an agate mortar and igniting the fine material in a platinum crucible over a strong blast until constant weight was attained. This oxide, cooled in a desiccator, was ground in an agate mortar to pass 200-mesh, and the percentage of CaO determined gravimetrically; the result was 99.98, as compared with the theoretical 100%. The CaO so prepared was used as a standard throughout the succeeding tests. Similar weighed portions were titrated with decinormal hydrochloric acid and oxalic acid, using phenolphthalein as an indicator, requiring 44.2 c.c. of hydrochloric acid or 44.6 c.c. oxalic acid to complete the reaction.

The weight of lime to be taken was calculated so that each cubic centimetre of oxalic acid solution would represent 1% of CaO, as given in the formula:

Lime. Lime. Oxalic. Oxalic.
56.09 : x : : 126.048 : 1.46068, in which $x = 650$.

This weight, 650 mg., was used in all the tests, and the table shows the results, which are sufficiently satisfactory for a technical method. The titrations were made in the cold by introducing 650 mg. of the sample into a 300-c.c. Erlenmeyer flask containing 50 c.c. of distilled water, using phenolphthalein as an indicator.

RESULTS OF TITRATION TESTS FOR CALCIUM OXIDE, USING OXALIC ACID

Calcium carbonate present. %	Calcium oxide present. %	Calcium oxide determined. %
95	5	5.2
90	10	10.3
85	15	15.3
80	15	20.3
75	25	25.0
70	30	30.2
65	35	35.0
60	40	40.0
55	45	45.0
50	50	49.8
45	55	54.5
40	60	59.9
35	65	64.8
30	70	69.6
25	75	74.5
20	80	80.2
15	85	84.8
10	90	90.0
5	95	94.7
0	100	100.0

The results given in the table indicate that calcium oxide in the presence of calcium carbonate can be determined by this method with a fair degree of accuracy. Silica, present in most limes, does not interfere. Magnesia, also present in most limes in greater or lesser amount, is slightly soluble in water, and shows a faint reaction with the indicator; but it is of no value as an alkali in cyanide work and should not be shown in a determination of the available alkali in lime to be used for that purpose. Fortunately, the point where the alkalinity due to calcium oxide stops is readily recognized after a little practice, for the color is a vivid pink, while that of magnesium oxide is faint. Moreover, the color in the titration of magnesium oxide disappears with the addition of only 0.1 or 0.2 c.c. of oxalic acid solution, and returns very slowly and feebly, while that of lime is rapid and sharp. This is illustrated by the fact that a titration of pure calcium oxide requires only 5 min., while the same amount of magnesium oxide requires 3.5 hours. In order to test the oxalic-acid titration in the presence of magnesia, two samples of limestones containing magnesia were ground to 200-mesh, ignited in a platinum crucible to constant weight, and titrated. The results obtained indicate that the magnesia does not interfere. Its presence can be judged by the behavior of the titration, and the approximate amount can be quite accurately estimated by continuing the titration, if one has the time needed.

Iron oxide in considerable amount is sometimes present in impure limes, and it obscures or masks the color of the indicator, but if the precipitate be allowed to subside the titration may be carried out to within 1% of the correct result. The determination of the amount of carbonate present in an imperfectly burned lime may be carried on as follows: Grind the sample to pass 200-mesh, weigh out 650 mg. and make the titration in the usual manner; call this result, available CaO. Ignite 650 mg. of the finely ground sample in a muffle or over a blast-lamp, and make a second determination. Subtract the second result from the first, divide by 1.78, and the result will be the amount of carbonate present.

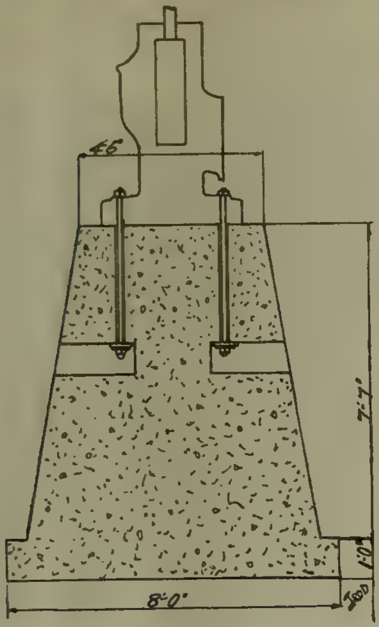
[*] Abstract of a paper presented at the San Francisco Meeting of the American Institute of Mining Engineers.

Battery Foundations

By F. E. Perkins

*The accompanying illustration shows a concrete foundation in connection with a 20-stamp mill in a Mexican mill. In some cases the stamp mortar, instead of being mounted directly upon the concrete block is mounted upon a casting which is called the sub-base. This has the advantage of spreading the mortar and the impact of the stamp over a larger area than is found possible with the standard base cast integral with the stamp mortar.

The accompanying illustration shows the concrete mortar block in connection with stamp mortar mounted directly upon the concrete. It will be noted that the base of mortar is made very heavy and thick; also wider than the base of stamp mortar when used in connection with a wood mortar block. The width of the base of the standard mortar when used in connection with a wood mortar block is usually 2 ft. 4 in., whereas, in the case of the stamp mortar in which the mortar is mounted directly on the concrete mortar block, the width of the base is 3 ft. 4 in. The advantage of the sub-base is in increasing the bearing area on the concrete to a width of 4 ft., and in addition, the added weight of the sub-base makes a heavy mortar with which it becomes possible to greatly increase the crushing capacity due to the greater weight of the anvil. It is customary to place packing rubber about ¼ in. thick between the cast iron base of the mortar and the upper surface of the concrete mortar block, not for the purpose of making a cushion, but rather to correct the irregularities of the surface of the concrete mortar block. The bottom of the mortar, as well as the bottom surface of the sub-base, are both machine-finished, and the top of the concrete mortar block should be made as smooth as possible.



SKETCH SHOWING DETAIL OF HEAVY FOUNDATION.

The proportions of material used in the construction of these concrete mortar blocks is as follows: 1 part by volume portland cement; 3 parts by volume freshly screened sharp sand; 5 parts by volume freshly broken rock, of any suitable character for concrete work, material to pass 3-in. diam. ring. This proportion is continued to a point within 2 ft. of the upper surface of the concrete mortar block, when it will be well to change the proportions of the material as follows: 1 part by volume portland cement; 2 parts by volume freshly screened sharp sand; 4 parts by volume freshly broken rock, passing 1½ in. diam ring. The upper layer of 6 in. from the top surface of the concrete mortar block should be constructed with the following proportions of materials: 1 part by volume portland cement; 1 part by volume freshly screened sharp sand.

The upper surface should be level and finished as smoothly as possible to give a true surface so that the stamp mortar or sub-base may be mounted directly upon this surface, requiring only the ¼-in. rubber packing to make a perfect joint. Grouting should not be used in placing the mortars in position, for such a thin layer of cement would be gradually broken from the impact of the stamps. The foundation rods are shown in the drawing with pockets for removal of the nuts on the lower ends of the rods in case of breakage.

In some cases separate mortar blocks are used for each 10-stamp battery, or in some of the mills a solid concrete block has been built under the entire 100 stamps, or ten batteries of ten stamps each, without any expansion joints whatever, and after several years service the concrete block appears to be in perfect condition.

*Abstract from *Cement Age.*

Electrolytic Oxygen in Cyanide Solutions

By T. H. Aldrich, Jr.

*There are two conditions generally prevailing upon the earth—those within atmospheric influence, tending toward oxidation, and those away from atmospheric influence, tending toward reduction. Practically all mineral substances from mines of any depth are in a reducing condition. Since the cyanide process, in order to dissolve silver or gold, requires that the prevailing conditions under which it operates shall be oxidizing, and the material usually acted upon being of a reducing character, it becomes necessary to supply oxygen to the solution carrying the cyanide. This oxygen is usually supplied through the medium of dissolved air in the solution, or by the use of one of various chemical compounds, which upon combining with the solution or the ore give off a part of their oxygen. In a dissolving race between the oxygen of the air and the reducing agents from the ore, if the reducing agents predominate, cyanide will not dissolve the gold from the ore. In many cases it will dissolve some of the gold, because in a mass of irregular shape some of the gold particles might be exposed upon the outside surface of a particle of rock; but if the solution had to penetrate through cracks, the side-walls of which were lined with reducing-agent-producing material, before the solution carrying oxygen could reach the gold it would have lost its oxidizing power. For this reason in many cases cyanide solutions will produce only an incomplete extraction of the gold or silver present.

It occurred to me that since water is composed of hydrogen and oxygen, if it be decomposed by the electric current, the hydrogen would bubble away and the oxygen would be carried by the solution. This was tried in December 1908 upon an ore carrying amorphous iron sulphides from which all the gold could not be dissolved by cyanide with simple air-agitation, no matter what the cyanide strength or how great the time. The process was tried first in an inverted bottle with the bottom cut out, the air being forced in through a glass tube in the cork to agitate the pulp. Two lead plates were inserted in the agitated pulp at the top. These plates were about 4 in. long and 0.5 in. wide, and $^1/_{16}$ in. thick. Through them was passed the current of an incandescent lamp, which gave about 0.25 ampere of current. The results were excellent. The value of the ore was $4 per ton. It was ground in a tube-mill so that 60% passed a 200-mesh screen. The value of the tailing, after 48 hr. agitation with air alone, was $1.25; but after agitation for 2.5 hr. with air and electrodes as described, the tailing was reduced to 40c. This typical result was verified many times, with uniformly good results.

---

*Abstract of a paper presented at the San Francisco Meeting of the American Institute of Mining Engineers.

In testing the solutions, a 2-lb. solution of cyanide is test 10. The alkali is tested on the basis of ten points over and above the alkali due to the cyanide, test 10 being a 2-lb. solution of caustic soda. The reducing agents were tested with a 1% solution of potassium permanganate, 1 c.c. of which in 10 c.c. of the solution, after acidulating, equals test 10, it being much easier to keep track of these solutions by simple numbers than by keeping the records in pounds per ton.

Numerous tests were made in order to determine a proper electrode. Lead was found to be the best material. Many other substances, such as carbon, worked very well, but with the alternating current, there being no consumption of the lead electrode, lead proved most satisfactory.

The following tests upon the working solution show the effect with iron and lead electrodes. All the tests were made at the same time and with the same solution, using a direct current of 0.25 ampere.

Lead electrode:	KCN.	Alkalinity.	Dbl.	Reduction.
Before	8	+1	5	6
After 4 min.	12	+2	0	4
After 10 min.	12	+3	0	3
Iron electrode:				
Before	8	+1	5	6
After 6 min.	7½	+6½	0	3
After 12 min.	6	+7½	0	2

(Showing destruction of the cyanide.)

There seems to be a regeneration of cyanide, and the process is certainly cheaper than any added oxidizer or even air-agitation of the solution. I found by numerous experiments that an alternating current was as effective as a direct, and had the additional advantage of giving no deposit on the electrodes at lower current-density, and with lead there was no consumption of the electrodes even where the ore-pulp flowed over the electrodes.

As finally used in practice in January 1909, a battery, supplied with alternating current, was placed in the barren sump. This battery consisted of 18 plates in series, each plate 6 by 6 in., with 110 volts between the two. The plates consumed 15 amperes, and produced sufficient oxidizing effect, or whatever other effect it may be, to keep the solution in condition to treat daily 40 tons of this ore. These plates, made of ⅛-in. sheet lead, were built so as to form hollow rectangles in section, the rectangle being 6 in. high, 6 in. long, and 1.25 in. wide inside. The two ends were lapped at the top and holes punched. The plate was bolted to a paraffined plank 1 by 6 in. on the top side; 18 of these plates were connected in series. The distance between any two plates was ⅛ in., and, of course, the current would travel principally across the ⅛-in. gap, instead of around the 1⅜-in. gap, from plate to plate. Lead wires were used from the surface of the solution down to the plates. The ore was ground in the tube-mills so that 60% would pass a 200-mesh sieve. Previous to using the batteries in the sump, the extraction in the tube-mill was 20% during grinding; after the batteries were used, the extraction in the tube-mill was 75%. The effect of the batteries seemed to build up in the solution gradually and to lose from the solution gradually when the operation of the batteries was discontinued.

During two months in the fall of 1910 the mill was working coarsely-ground, partly-oxidized ore carrying considerable sulphides. The water at the hydro-electric plant was low, and the use of the batteries was discontinued because the mill was driven by steam, and no arrangement had been made to supply alternating current from any but the hydro-electric plant. During this time the tailing on $4 ore went up to $1.25 per ton, and immediately after the rains gave sufficient water to drive the hydro-electric plant, the tailing assays diminished until 20c. per ton was reached on identically the same ore with the same head-assay; moreover, the reducing agents dropped from 16 to 4. The time occupied in getting the working solution up to this condition was two weeks. I consider that this process owes its value almost entirely to the presence of oxygen due to electrolysis, putting the solution ahead in the race for the reducing agents and causing the gold and silver to dissolve in spite of the reducing agents. However, it does not stop the reducing agents from dissolving also, and although it produces solution of the gold in spite of the reducing agents, it does not help precipitation, and if the reducing agents are not decomposed by the batteries—and all of them are not—they build up in the solution rapidly to a point where zinc-shavings will not precipitate the gold.

Of course, in practice the cyanide solution contains reducing agents of many kinds. The electrolytic action seems to reduce the influence of some, but not all of them. For example, I experimented on some highly-graphitic ore, and whether the normally-poor extraction was due entirely to the graphite or not, I do not know; but the solution, after electrolyzing, gave a very much better extraction than before electrolyzing. The action seems to decompose the sulphocyanides and the soluble sulphides, but not the alkaline sulphides and all of the many others always present. A test on the electrolyzed solution 18 months after the batteries were installed showed:

	KCN.	Alkalinity.	Dbl.	Reduction.
Before	8	1	0	15
After 10 min. electrolysis	8	1	0	15

showing that the solution remained practically the same, or was electrolyzed as much as was necessary. However, testing some of this same solution further by placing a piece of gold leaf upon its surface and allowing it to float, the gold leaf was dissolved in 71 min. on the working solution and in 50 min. on the re-electrolyzed solution, showing that the additional electrolysis, although it had no apparent effect on the solution, gave an increased dissolving rate. Grease in the ore or on the surface of the barren sump seemed to dissolve very rapidly in the treated solution and slowly in the untreated solution. The tanks were tarred on the inside and coated with black oil outside, and more or less grease was frequently floating upon the surface of the solution where this effect was noticed.

Since the installation of this process it has treated successfully at this plant 25,000 tons of ore of all kinds, oxidized, partly oxidized, and sulphides. Previous to the use of the batteries, in treating sulphide ores, the average cyanide consumption was 1 lb. per ton, in some months running as high as 1.1 lb. After the use of the batteries the average was 0.45 lb., running for some months as low as 0.23 lb. per ton of ore treated. I tried using batteries in the agitated pulp and in the solution, and found the result to be just as good if the plates were inserted in the barren sump as if inserted in the agitated pulp. The original lead plates placed in the barren sump are still there and in operation. They cost about $4 to insert originally, and were inspected after 26 months of practically continuous service, and are today just as good as when they were first put in use. I have applied for no patents on this process and do not expect to, and anyone is free to use it. It should be a cyanide-saver, an accelerator, and a general solution-purifier.

Mine Output in Texas, 1910

The value of the mine production of gold, silver, copper, and lead in Texas in 1910, according to C. W. Henderson, of the U. S. Geological Survey, was $209,061, against $199,446 in 1909. The quantity of ore treated was 21,917 tons, against 21,762 tons in 1909. The production of gold was $423, againt $314 in 1909; that of silver was 380,322 oz. valued at $205,374, against 374,444 oz. valued at $194,711; that of copper was 3157 lb. valued at $401, against 3862 lb. valued at $502; and that of lead was 65,068 lb. valued at $2863, against 91,140 lb. valued at $3919. The metal production of Texas is therefore mainly in silver and lead, and much the greater part of this is from the well known Presidio silver-lead mine, in the Shafter district of Presidio county. The output of gold, silver, copper, and lead in Texas is all from trans-Pecos or far western Texas.

The Ashio Copper Mine

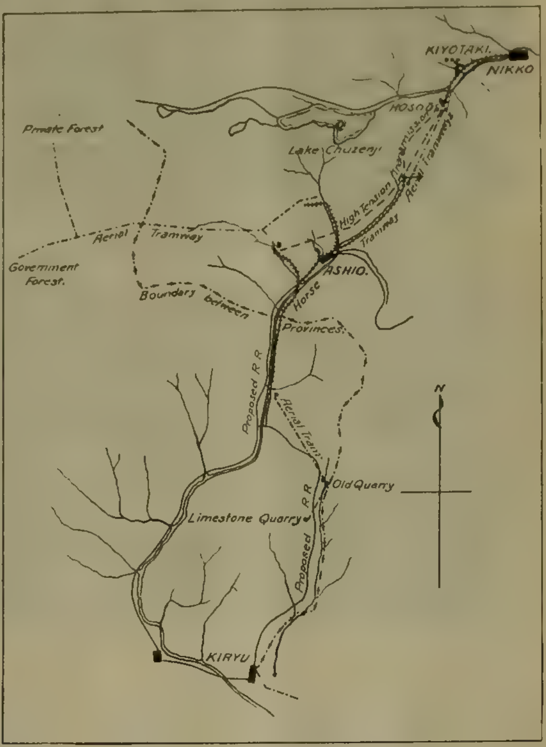
By Thomas T. Read

The Ashio mine, one of the principal objective points of the Japanese excursion of the American Institute of Mining Engineers, is of great interest, because it is the most productive copper mine in Japan, though closely pressed for the leading position by the Besshi mine and the Kosaka mine. The outputs of the three for 1910 are given as 11,843,406, 11,132,371, and 10,500,501 *kin*,[*] respectively. It is the largest of some fifteen copper mines owned by the Furukawa company, the Osarizawa, the Furokura, and the Kune being the most important of the others. The company also owns three silver mines and seven coal mines, and occupies the dominant position in copper mining in Japan, which is the third most important copper producing country of the world. The mine, which is therefore of great relative importance, has further interest in the fact that it is practically privately owned. It was discovered in 1608, but its active development dates from 1877 when Mr. Ichibei Furukawa acquired it and worked it so successfully that he gradually acquired nearly all the more important copper and silver mines in the northeastern part of the main island (Hondo). These later passed into the possession of his son, Jun-Kiche Furukawa. It was my privilege to form the acquaintance of Mr. Toranusuke Furukawa, the present head of the company, some years since, and the following description is based upon a brief visit to the property during the summer of 1910, though I have supplemented my notes by the data given in 'Mining in Japan, Past and Present,' published by the Bureau of Mines of Japan. To those interested in the history of mining in Japan and the primitive methods employed in early times, this volume will prove a veritable mine of interest and information.

MAP OF NIKKO DISTRICT, JAPAN.

The Ashio copper mine is 100 miles north-northwest of Tokio near the headwaters of the Watarose river, in the province of Shimotsuke. The place may be more closely defined by saying that it is fifteen to eighteen miles southwest of Nikko, as that little town, nestling in a deep canyon with majestic cryptomeria trees rising almost to the rim, is known the world over for its beautiful temples and tombs of the Tokugawa shoguns. Thousands of Americans yearly come to see these beautiful examples of ancient art and depart without knowing that, but a few miles beyond, the new Japan is typified by large mines, smelters, and a copper refinery operated with the highest degree of technical skill. The relative position of the mine is shown on the small map, supplemented by the larger ones. A short distance north of the mine is Lake Chuzen-ji, a favorite watering place for the members of the foreign embassies in Tokio, and if a visitor could spend but a day at the Nikko temples, another at the refinery at Kiyotaki and the hydro-electric power house at Hosoö, and two days at the mine, returning by Lake Chuzen-ji and the falls of Kegon-no-taki, this alone, in my opinion, would be well worth the journey to Japan.

The mine can also be reached by the way of Kiryu, but the river is not navigable and at present supplies are brought to Nikko upon the railway, transported to Hosoö in tram-cars drawn by bullocks, and sent across the mountain to a surface tramway which takes them the remaining distance to the mine. The mountain is completely encircled by a tramway since Kotaki and Honzan are connected by a tunnel passing through what are now the upper workings of the mine. Visitors are carried to Ashio in a *kago,* seen in the illustration, a comfortable and convenient method of travel to one of Japanese physique, but not adapted to directors of corporations. The order in which the visitor is likely to see the property is refinery, power-house, tramways, smelter, ore-dressing works, and mine, but it will be more logical to take them up in reverse order.

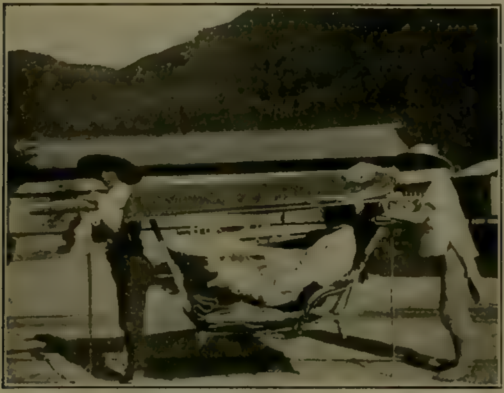


SURFACE MAP, ASHIO MINE.

The mountain which contains the mine is a volcanic plug or neck of liparite, upthrust through Paleozoic sediments, clayslate, sandstone, and quartzite. This is cut by innumerable almost vertical veins belonging to two series, known as the 60° series and the 100° series, their relations being seen in the accompanying sketch. The veins pass out of the liparite into the surrounding sediments, but quickly thin out and disappear, the whole forming as characteristic an example of fissuring during cooling and subsequent vein filling by the waters of dying vulcanism as could be desired. The order of vein filling has been determined as, (a) quartz, (b) chalcopyrite, associated with some pyrite, (c) pyrite, sphalerite, and galena, (d) quartz. The chalcopyrite occurs in crystals and crystalline masses in the gangue and carries silver in small amount, rarely as much as a couple of ounces per ton, as well as traces of gold. Both the galena and sphalerite, which are constantly present in small amount, carry several ounces of silver. Pyrrhotite and arsenopyrite occur in variable small amounts and in the upper portions of the veins a great variety of minerals occur, native copper, cuprite, bornite, melaconite, and other copper minerals, calcite, vivianite, fluorspar, heulandite, and apatite. A striking feature is the great number of the veins and the narrowness of those worked. It naturally follows that working in, and more especially development in closely faulted ground, can easily become very expensive unless carried on with much care and skill in direction of the work and the employing of contract labor, as far as possible. The low costs actually obtained are due both to the skill in direction of the work and the employing of contract labor, as far as possible. The contract miners are paid a variable sum per 10 ft. advance in driving, the amount being fixed by an involved computation, the cost of powder being deducted and the ore paid for at the rate of 5 *sen* per *kwan*, the contract basis being so arranged that the miners will net an average wage of 80 *sen* per day. Trammers receive 50 *sen* per day; the lowest wage is paid to the women and girls, who do only light surface work, receiving 17 *sen* per day. No women are employed underground. The company also has a supply department and sells its workmen rice at a fixed price which is usually below the cost price. This protects the workmen from sudden variations in the cost of food, and the company regards the cost of this service as a form of wages. Three 8-hr. shifts are employed underground, but only two shifts on surface work.

---

[*] 1 *kin* equals 1⅓ lb.; 1 *kwan* equals 8¼ lb.; 1 *yen* equals 49.8c. gold; 1 *sen* equals 1/100 *yen*; 1 *shako* equals 11.93 in.



TRAVELING IN A *kago*.

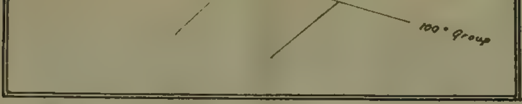


DIAGRAM ILLUSTRATING VEIN STRUCTURE, ASHIO.

Working is carried on through three adits, or more accurately, an adit and a tunnel, as the adits from Honzan and Kotaki connect. The Tsudo adit (see map p. 488) is 450 ft. lower than these; below there are 8 levels, 110 ft. apart. Two winzes connect these with the Tsudo adit-level; one of these has four hoisting compartments, the other being chiefly for pumping and as a man and airway. Workings extend for over 1100 ft. above the Honzan tunnel level, giving a total depth to the mine of about 2500 ft., sinking being still in progress. There are 10 winzes altogether and the total length of the present workings is over 100 miles. The larger part of the work now goes on below the Tsudo level, as the upper workings are gradually becoming exhausted. The total number of veins exposed in the workings is over 300, and on 70 of them some work at least has been done. The veins are very narrow; 5 ft. of ore is considered unusually good, and my impression was that 3 to 5 ft. of vein carrying 9 to 15 in. of ore was the more usual condition. Various types of stoping drills have been experimented with, the final conclusion being that it was cheapest to cut with picks in such narrow stopes, as the cost of labor is low and the vein matter it not hard. In driving the main drifts Leyner drills are used; over 50 of them are employed in the mine and the management reports itself as well pleased with their service, though repairs have been heavy, possibly due to the inexperience of the miners with the drill, as they had not been in use long at the time of my visit.

MOUTH OF ADIT, HONZAN.

The Tsudo adit is double-tracked throughout and equipped with electric haulage, using 15 and 25-ton locomotives, as in the other adits. Wooden cars of one ton capacity are used, as the acid mine-water rapidly destroys iron cars. With so many veins in the moist climate of Japan, it would naturally be expected that the mine would be wet. The water is kept out as much as possible by cementing over the outcrops of the principal veins where they outcrop in gulches on the mountain side. The adits drain the workings above them, some 400 cu. ft. per minute flowing through the Tsudo adit. About 85 cu. ft. per minute of this is pumped from the seventh level below the adit, using Riedel plunger pumps and also an Escher-Wyss turbine pump, both being driven by induction motors, and lifting in three stages. There is also a small Cornish pump to act as a sinking pump in the winze. Altogether some 15 types of pumps have been employed. The main levels are lighted by electricity and equipped with telephones. In order to reduce the cost of piping and line losses, seven electric-driven Leyner air-compressors are distributed throughout the working places.

Ore-dressing plants are near the mouth of each adit, the principal one being at Tsudo, where a branch adit near the mouth connects with a 100-ft. shaft, through which the ore is hoisted to the mill, thus giving the necessary fall. The surface water which percolates through the waste and tailing heap is collected in separate launders in the main adit and run over scrap iron. In this way some 40,000 lb. of copper per month is recovered at a very small cost. Ore-dressing practice is much the same at the three mills, but as the one at Tsudo is the most complete I shall confine my description to that. Some 250 tons per day is handled at this plant, and 350 more at the two mills at Kotaki and Honzan. The mill at Tsudo is a double one, one part for rich ore and the other for the more usual low grade ore. The ore as mined is from 1.5 to 9% copper, averaging about 4%; this is concentrated to about 12% copper. The mine ore is dumped on an 80 mm. grizzly, the oversize being sorted into rich ore, waste, and low-grade ore, which is spalled to pass the grizzly. The undersize goes to bins, whence it is drawn upon a conveyor-belt of Japanese cotton. This does not last long, but is enough cheaper to compensate for the shorter life. This delivers to a belt-conveyor which feeds a set of trommels, 40, 25, 17, 11, 7, 5, and 3 mm., respectively. The 40-mm. stuff is sorted by women into rich ore, poor ore, and waste. The rich ore is sent to the other dressing works, the poor ore is recrushed, first in jaw-crushers and then in rolls. The different sizes of finer material are jigged in 3-sieve jigs, the coarse middling being recrushed. The finest material is classified and treated on Overstrom and Wilfley tables; Cammett tables and Evans slime tables are employed at the other mills. The most notable feature of the milling practice, like the mining, is the low cost at which an involved series of operations, requiring much labor and personal attention, are carried on. The volume previously referred to states that the power used by the three mills is derived from eight motors, yielding a total of 318 hp., and two Pelton water-wheels. As this corresponds to little more than $^6/_{10}$ hp. per ton-day it is remarkable, if true.

It would be interesting to trace the development of the present smelting plant from the *yama-shita* and *mabuki* first employed, especially as the latter presents a curious analogy with the production of blister copper in a converter, but considerations of space forbid. Until recently the fine ore was roasted in McDougall furnaces and many ingenious methods were tried for agglomerating the calcines, the most notable being a device of the superintendent whereby a shell was cast around each bucketful of calcines in an elevator. Blast furnaces have always been used for smelting, and converters for bessemerizing the matte were adopted in 1893, the year after Manhes American patents were issued. Since then all the types of converter except the Stalmann have been tried, and they are now using three 3 ton converters of the Anaconda type and two 5-ton stands of the Bisbee type. Liparite, mixed with clay, is used as a converter lining and as it probably has some such composition as 70 to 75% SiO_2 and 10 to 12% Al_2O_3, it gives a sticky slag. I did not learn whether this was employed because of the lack of pure silicious material, or because the low cost of labor for relining made it advisable to employ what is practically low-grade ore for converter lining. The composition of the matte for the day preceding my visit was:

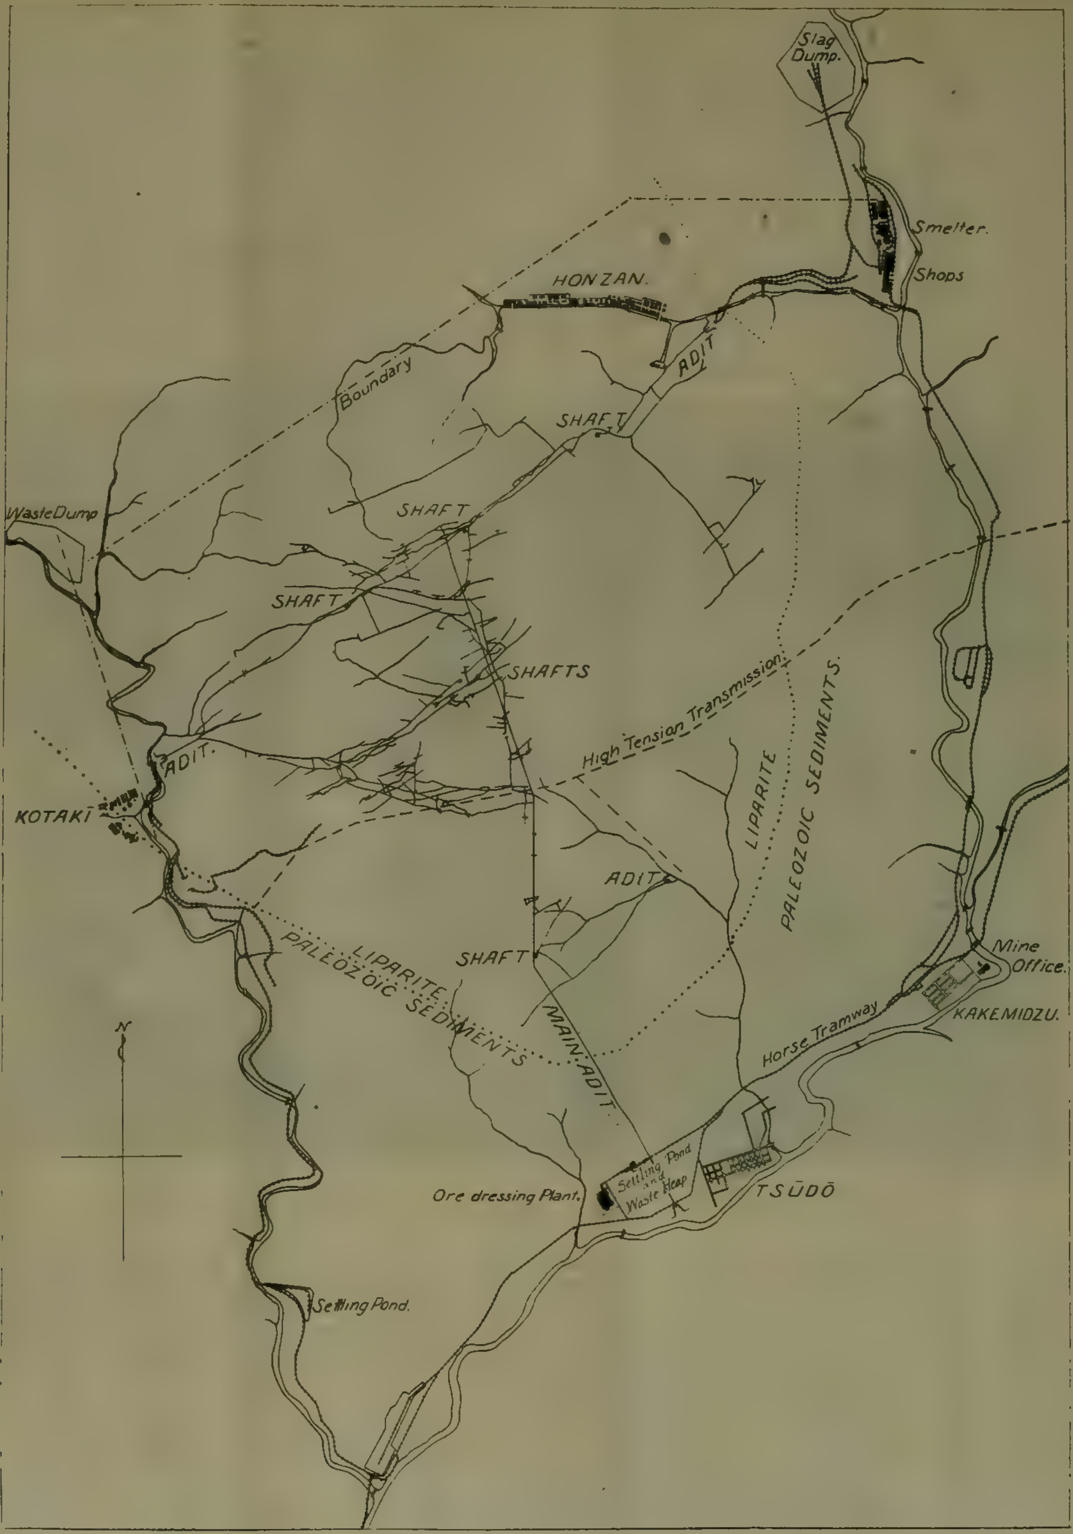
BLAST-FURNACE, ASHIO.
SETTLING-PONDS.

LEYNER DRILLS AT WORK.
ORE-DRESSING PLANT, KOTAKI.

	%
Cu	33.5
S	25.0
Fe	36.6
Pb	1.44
Zn	1.20
As	0.72
Ag	0.03

No effort is made to save the lead and zinc.

The average product to be smelted has approximately this composition: Cu, 12%; Fe, 28%; S, 25%; SiO_2, 32%. The small proportion of lump ore goes directly to the blast-furnace. The fine is pot-roasted, according to a system devised by the resident engineer, in conical pots 8 ft. diam. at the top and 5 ft. at the false bottom, giving a depth of charge of 4½ ft. Nothing is added as a binder, the rate of oxidation being controlled so that the sulphides sinter to just the required degree during the roast. Each pot



GENERAL MAP, ASHIO MINE.

holds 7 tons and burns 12 hr., the combustion being started by the use of a small amount of coal and wood. The blast is furnished by No. 6 Root blowers. The operation of these pots seems to be entirely satisfactory.

Electric elevators lift the charge to the charging-floor. The relative proportions are: ore, 10 parts; limestone, 3 parts; converter slag, 2 parts. Smelting is done in 160 by 42-in. Allis-Chalmers water-jacketed matting-furnaces at the rate of about 2 tons per square foot of hearth per day, only a little over 6% coke being used, and a blast pressure of 22 oz. employed. The slag approximates 40% SiO_2, 30% FeO, 12½% CaO, and 7½% Al_2O_3, and carries 0.21% copper. It is necessary to convey it some distance up the valley where there is space to dump it. I am told that it is now granulated in water as it flows from the forehearth. The blast-furnace gases pass through dust chambers to the main flue, which, as seen in the illustration, contains a series of chambers in which a rain of limewater is kept falling, much in the manner of a scrubber, the resulting sludge being thrown away. In spite of the care taken the escaping gases still do damage, because of the high SO_2 content, the dampness of the climate, and the narrowness of the valleys. Fortunately there is but little nearby agriculture and the damage claims are correspondingly small. The combination of smelter fume and the demand for timber and fuel has resulted in denuding the hills, and the latticework by which erosion is prevented can be seen in the background of the illustration. This, and the necessity for impounding the tailing from the ore dressing, and the neutralizing of the acid waters from the mine before allowing them to escape into the river, are a not inconsiderable addition to the cost of copper production, but a scrupulous performance of these duties is exacted by the Government in order to secure permission to continue working.

SMELTING PLANT, ASHIO.

HEADGATE, HOSOÖ POWER HOUSE.

Over 7000 workmen are employed at the mine, about 3000 being employed underground. The electric power for the mine, mills, and smelter has been obtained from 10 power-stations on the Watarose and Daiya rivers, the turbines having a total of some 5000 hp. The expansion of the work calls for increased power, and the principal station, at Hosoö, has recently been doubled in capacity. The headgate of the penstock for this plant is shown in the illustration. The most improved types of direct-connected generators are employed at this plant, a visit to which is one of the principal features of the trip from Nikko to Ashio. The power is transmitted by high-tension lines to the points desired. As previously mentioned, supplies are brought in from Nikko and the blister copper is sent out by a wire-rope tramway from Hosoö. In addition to this there are several other aerial tramways, one of the most important connecting the mines with the forest reservations from which the supply of timber is derived. The mountain in which the mine is situated is girdled by surface tramway tracks, of which there are many miles. An interesting feature is the numerous types of bridges employed; almost every type of truss is represented, including some original ones. The care with which every detail of the work about the mine and surface plants has been worked out is well worthy of study.

The electrolytic refinery is at Kiyotaki, but a short distance up the Daiya river from Nikko (see map). Here is refined not only the blister copper from Ashio, but from the other mines of the Furukawa company as well. The refinery has its own hydro-electric power-plants with 195 *shako* fall. The ingots from the mines are remelted in a reverberatory furnace, brought to proper pitch, and cast into plates, which are rolled into anode sheets and cut to the proper length. The general features of the plant are seen in the accompanying illustration. Three vats in series, each containing 40 plates, are placed *en cascade*, the electrolyte, after passing out of the lowest vat, is filtered through coke and pumped back to the uppermost tank. The volume previously referred to gives 234 as the total number of vats, but my own notes give double the number. The electrodes are in series, the copper being dissolved from one side and plated on the other. When the operation is finished the electrodes are removed, scrubbed, melted down in a reverberatory furnace, brought to tough pitch, and cast into wire bars, cakes, and ingots. The making of copper wire is an important feature of the work, and is carried on with a high degree of skill. A Bates and Peard annealing furnace is employed. The finished product enjoys a high reputation in Japan, and the Furukawa trademark is widely known. The gold and silver slimes are cupelled in an English cupelling furnace. A great deal of work has been done on the problem of recovering the small amount of lead present in the blister, but I understand that no commercial results have yet been obtained in the experiments.

TANK ROOM, KIYOTAKI REFINERY.

The blister copper has a high tenor, the composition before refining being given as 99.7%. The yearly production of the works is stated at 5000 tons of copper wire, 2000 tons of copper ingots, and 500,000 oz. of refined silver and gold. The latter metals, of course, are chiefly derived from the bullion of other mines owned by the company. In concluding this description a brief reference should be made to the Kune mine in Totomi province, where there are enormous bodies of pyrite associated with chalcopyrite. Unfortunately the mine is distant from transportation facilities, nor will the Government permit the erection of a smelter, so that its development has been hindered.

Metal Production of Colorado in 1910

The total value of the mine output of gold, silver, copper, lead, and zinc in Colorado in 1910, according to Charles W. Henderson, of the U. S. Geological Survey, was $33,673,879, against $33,907,140 in 1909, a decrease in value for 1910 of $233,261.

The production of gold showed a decrease of 71,705.20 oz. and of $1,482,278 in value; the output of silver, a decrease of 393,035 oz. and of $34,186 in value; the production of copper, a decrease of 2,632,511 lb. and of $358,205 in value. The output of lead, however, showed an increase of 3,903,483 lb. and of $243,921 in value; and the production of zinc (figured as spelter), a notable increase of 25,879,388 lb. and of $1,397,487 in value.

Of the gold output, the Cripple Creek district produced $11,002,253 in 1910, or 53.7% of the total gold from all sources in Colorado. This was a decrease of $468,420 from the output for 1909. Most of the Cripple Creek mines were operated with reduced forces, the operators preferring to wait until the mines were fully unwatered rather than maintain a normal output at a heavy cost for pumping. The gold output of Ouray county decreased $848,978 from the heavy output of 1909, which was an increase of $1,016,127 over the yield of 1908. In La Plata county the gold output increased $263,725 in 1910, in San Miguel county there was an increase of $209,742, and in Gunnison county an increase of $125,479. The placer output of gold was $395,465, a decrease of $63,027 from the 1909 production.

In the production of silver in Colorado in 1910, Lake county (Leadville) made 39% of the total State yield. This county showed a decrease in output of 101,627 oz. in 1910, against an increase of over 500,000 oz. in 1909. There was decreased production of silver also in Pitkin, San Miguel, and many other counties. Increased output of silver was credited to Chaffee, La Plata, and Ouray counties in 1910. The chief silver-producing counties in Colorado in 1910 were Lake, San Miguel, San Juan, Mineral, Pitkin, Clear Creek, and Ouray, in the order named; these counties combined furnished nearly 87% of the total State production.

In Colorado lead production in 1910 there were considerable increases in output from San Miguel, San Juan, Summit, Ouray, Chaffee, Eagle, Gunnison, Hinsdale, and Pitkin counties, and decreases in Lake, Clear Creek, Mineral, Boulder, Dolores, and Gilpin counties. Lake county ranked first, and was followed by Pitkin, San Juan, Mineral, and San Miguel in the order named.

Of the Colorado zinc output of 77,089,648 lb., Lake county produced 73%, with an increase in output for the year of 17,730,130 lb. Shipments of the newly discovered zinc carbonates from Leadville were relatively slight in 1910, but the new finds promise larger outputs of both zinc and lead from this famous old district in the future. Increased production of zinc was also made in Eagle, San Juan, San Miguel, Mineral, Clear Creek, and Park counties in 1910. The only material decrease was in Chaffee county. Until 1902 the zinc mining and smelting industries were of slight relative importance in Colorado, but they have been of yearly increasing importance, and in 1910 they surpassed those of lead and of copper.

The amalgamating, cyaniding, and chlorination mills of Colorado produced less bullion in 1910 than in 1909, although a larger tonnage was treated; and despite a considerable increase in tonnage of concentrate from concentrating mills, less silver and copper were produced from concentrates, and there was only a slight increase in gold production, although there was a material increase in the output of lead and zinc. There was a decreased tonnage of ores smelted in Colorado in 1910 and decreased output of metal from smelting ores. The mills treated 79% of the Colorado ores and the remainder was smelted crude in 1910.

MINE PRODUCTION OF GOLD, SILVER, COPPER, LEAD, AND ZINC IN COLORADO IN 1910, BY COUNTIES

Counties	Ore treated. Tons.	Gold.*	Silver.* Fine ounces.	Copper. Pounds.	Lead. Pounds.	Zinc. Pounds.	Total Value.

*Includes placer production.

Goldfields of Coker Creek, Tennessee

By George H. Ashley

*The following account is the result of two days spent in the Coker Creek goldfield during a rapid reconnaissance of Monroe county, the latter part of July. Coker creek flows in a broad, open valley, two miles wide by ten miles long, just at the western foot of the Unaka mountains, which there separate Tennessee from North Carolina. The upper half is in Monroe county and the lower half in Polk county, the two southeast counties of Tennessee. The presence of gold on Coker creek appears to have been known to the Cherokee Indians, living in that region, in the early part of the last century. From them the white people learned of its occurrence, and as early as 1827, it is stated, Jacob F. Peck and Le Grande Henderson entered the field and did some mining. The first gold reported deposited in the mint from Tennessee was in 1831, when $1000 was sent to Philadelphia. The output of gold from Tennessee from 1831 to 1853 is reported to have amounted to $46,023 by J. M. Safford.[1] He states that the largest piece of native gold found of which he had heard, weighed 12 dwt. In contrast with these figures I was informed that the most active work in this field did not begin until 1856 and continued to 1860. Possibly the most profitable clean-up was that by Thomas Cooper, who, as a result of three weeks' work, took out gold to the value of $39,600. In one case $300 was obtained by re-working an old abandoned pit. All told, Mr. Cooper is said to have taken from a tract of hardly more than one-half acre, $80,000. This included many nuggets, two of which weighed 1¼ lb., valued at $360 each. In 1905, according to 'Mineral Resources,' the Lonsdale Gold Mining Co. was prospecting a gravel deposit 6 ft. thick and 120 ft. wide; the Unaka Mining & Development Co. was building a dredge; and the Coker Creek Mining Co. was doing some prospecting. The Lonsdale company appears to have operated in Lot 4, Section 30. It is reported to have driven into a hill on that lot and to have found enough gold to warrant putting up a 10-stamp mill. The Unaka Mining & Development Co. owns some 360 acres in sections 19 and 20. After doing a small amount of hydraulicking, the company decided it would be better to work out the bottom lands before covering them with the tailing from the sluices. Several experiments were tried which failed and involved the company so heavily in debt that the leaders lost interest. The Coker Creek Mining Co. appears to have done no development work, but is still holding some 120 acres for future exploitation. Besides these companies, none of which are doing any development work today, placer mining by hydraulicking has been carried on, on a small scale, in several places.

In addition to these more or less metamorphosed sandstones and shales, numerous veins of quartz occur, and it is in association with the quartz veins that the gold is found. Though time did not permit a detailed study, enough was seen to convince me that these are true fissure veins. In parts of the field the quartz veins appear to be lacking. In others they are abundant, ranging from a fraction of an inch up to a foot or 18 inches. In one area 10 vertical veins were counted in a width of 10 ft., measured normal to the strike. The quartz veins appear to run in narrow belts, separated by wide areas without veins. The most notable of these belts is known as the Whippoorwill vein; and has been traced for at least five miles, and, judging by other known occurrences, may be traceable for several times that distance. In places this belt consists of one or two distinct quartz veins 3 to 18 in. thick (when 20 to 40 ft. apart), but at other places it is composed of a group of veins, averaging, perhaps, 2 to 3 in. thick. The individual veins are variable in thickness, though often even the very thin veins are traceable long distances on the surface, and the belt as a whole is readily traceable by the line of quartz fragments which strew the surface. In general, the body of the quartz is clear and milky, what the miner commonly calls 'hungry' or barren, but scattered through this are cavities of varying size, often cubical, showing that they formerly contained pyrite, though now containing only a brown or yellow coating of iron oxide. But the contact faces of the veins often appear to be almost entirely covered with a pitted surface of rusty color. From the appearance of the veins at the surface, it would seem evident that the gold will be found associated with pyrite as soon as mining reaches below the effect of surface waters.

Gold also occurs in the country rock. Pannings were made of the shale on either side of the Whippoorwill vein, the samples being taken from just outside of the contact for a distance of 10 ft., and these showed good 'color' and in one case a considerable nugget. A third mode of occurrence is in what Becker calls saprolitic material, that is, the weathered surface rock.

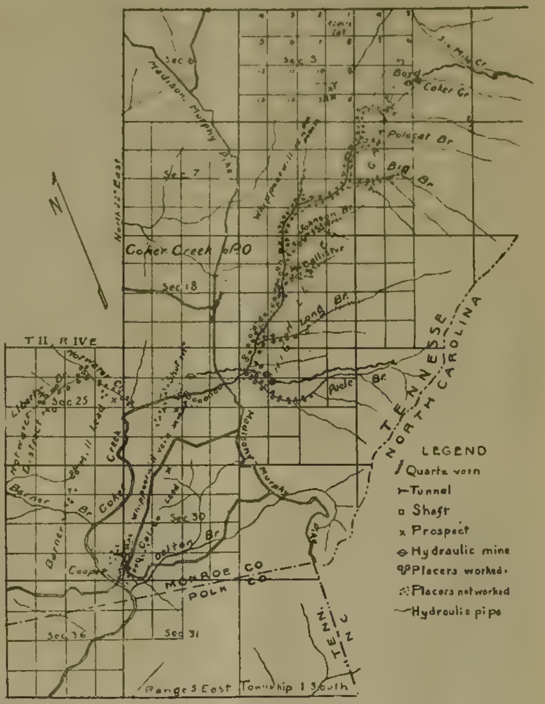

FIG. 1. SKETCH MAP OF PRINCIPAL PART OF COKER CREEK GOLDFIELD

Placer gold is also found in what may be called the high-level gravels. In some cases these correspond to the 'second bottoms'; in others to interstream areas of gentle slope. On the east side of Coker creek the land has an even, gentle slope for some distance to the foot of a sharp ridge of quartzite. The present stream channels are cut from 40 to 70 ft. below the level of this slope, becoming less as Coker creek is approached. A small amount of hydraulicking has been done in these levels, indicating pay-ground. Pannings made from these gravels give abundant 'colors.' The principal source of gold obtained to date is in the gravels of the present stream bottoms. Where the Madisonville-Murphy pike crosses Coker creek the bottoms are about ¼ mile wide, but gradually narrow up-stream. The side tributaries have rather narrow bottoms, ranging from a maximum of 100 to 200 ft. down to a few yards wide, and from a fraction of a mile to a mile long, depending on their size and length. Below the pike mentioned the bottoms on the creek vary according to the rock through which the stream passes. The depth of these stream gravels ranges from 2 to 6

---

*Abstract from *The Resources of Tennessee*, September, Pub. by Geol. Surv. Tennessee.

[1] 'Geol. Tennessee,' p. 490.

ft., or more. Very few of the gravels have been worked where the deposit was more than 6 ft. deep. As usual, the gold has been found mainly at the base of the deposit in contact with the underlying bedrock. In the past, the bottom 6 in. alone has been worked. Just below, where Six Mile creek and the head of Coker creek diverge after passing through the quartzite ridge, there is a relatively high slope, into which one or two test-pits have been dug by hydraulicking. These were made by Mr. Boyd, who carried his water from the upper part of Six Mile creek and dug several small pits 10 to 15 ft. deep. These show red dirt with boulders and masses of arkose quartzite, or fine conglomerate, the boulders being up to 2 ft. in diameter. It is reported that he took out of these small holes between $3000 and $4000. Other work on these high gravels has been carried on just north of Big creek, the gravels there being 15 to 20 ft. above the creek bottom, and reported to be 'on the gold streak.' Between Big creek and Johnson creek and 40 or 50 ft. above the creeks, digging has been done to a depth of six or seven feet on this upland slope. Farther southwest, just north of Peele branch, some recent hydraulic work has been done by the company which preceded the Unaka Mining & Development Co. Water was brought from the head of Peele branch through a 6-in. spiral, steel-riveted pipe. The gravel is composed of quartz, coarse conglomerate, and sandstone, in size up to two feet in diameter. It has a thickness of three or four feet. In addition to these areas which have been partly worked, there is a large territory of similar character practically untouched. Polecat creek has been worked for about a quarter of a mile from its mouth. The main valley at the mouth of Polecat creek has a width of about 150 yd. and has already been worked. Big branch has been worked for some distance, as well as Johnson branch. Considerable work has also been done on Long branch. At its mouth the main valley is from two to three hundred yards wide, nearly all of which has been worked. Considerable work has also been done on Peele branch, but in the broad bottom below the mouth of Peele branch on either side of the Murphy pike, practically only the stream channel has been worked, except a channel run by the dredge of the Unaka company. Mining has also been carried on up Hot Water creek bottoms, and Liberty creek.

In conclusion, the examination demonstrated that: (1) the Tennessee gold belt may prove to be an asset of the State, if its development be undertaken by men who know their business, using modern, up-to-date methods and machinery; (2) thorough, systematic prospecting and surveys will be necessary to demonstrate the feasibility of its profitable exploitation at any point, or in any district.

Finally, if anyone feels the lure of gold-mining in the blood, let him get a pan and pick and shovel, and lease the privilege of digging up some 40-acre tract, but don't invest in any mining stock. In the first case the investment is small, the outdoor exercise good for the health, and he may get enough gold to pay railroad fare and expenses. In the second case, the chances are nine out of ten that he will have ample time to reflect on an old adage about 'a fool and his money.' Gold mining in Tennessee, as in the other Appalachian States, has passed the first 'gold rush' stage. If any money is made from it in the future, it must be made as in the neighboring States, by men with abundant capital, thoroughly familiar with the mining business, knowing, or having in their employ, capable, trained mining engineers and metallurgists, and with ample opportunity to give the work their personal supervision and attention.

Metal Production in the Central States, 1910

The value of the mine output of silver, copper, lead, and zinc in the Central States for the calendar year 1910, according to B. S. Butler and J. P. Dunlop, of the United States Geological Survey, was $62,866,732, compared with $63,997,999 in 1909. The decrease in total value was occasioned by the smaller production of copper in Michigan, which yields practically the entire output of that metal in these States. The production of silver, lead, and zinc increased both in quantity and in value.

The output of copper was 11,358,616 lb. less in quantity and $2,144,954 less in value than in 1909. The increase in silver was 64,073 oz., in lead 3005 short tons, and in zinc 3447 short tons. About 90% of the silver, or 330,500 oz., was derived from the electrolytic refining of copper produced from copper ores mined in Michigan; the rest was obtained from lead ore produced in southeastern Missouri, southern Illinois, and Kentucky. Missouri produced over 94% of the lead and nearly 72% of the zinc. Wisconsin produced 2.5% of the lead and 14.5% of the zinc. The total quantity of ore mined in Michigan was 10,869,561 tons, having an average copper content of 1.025%, compared with 11,429,394 tons, averaging 1.06%, in 1909. The crude ore treated and the lead and zinc concentrate recovered in 1910, in short tons, were as follows:

		Concentrate	
	Crude ore.	Lead.	Zinc.
Arkansas	35,000	80	1,857
Illinois (northern)	111,078	126	9,871
Kansas	704,046	3,034	27,240
Missouri	12,742,420	248,058	256,167
Oklahoma	223,212	3,638	14,256
Wisconsin	1,032,052	5,608	94,502

The table below shows the output of silver, copper, lead, and zinc in the Central States in 1910, by States, and the totals for each mineral and each State in 1909 and 1910. Copies of the report, which is now in press, can be had on application to the Director of the Survey, Washington, District of Columbia.

PRODUCTION OF SILVER, COPPER, LEAD, AND ZINC IN THE CENTRAL STATES IN 1910

State.	Silver. Fine ounces.	Copper. Pounds.	Lead. Short tons.	Zinc. Short tons.	Total value.
Arkansas	....	....	63	994	$112,896
Illinois	2,022	....	373	3,549	417,208
Iowa	....	....	20	96	12,128
Kansas	....	....	2,412	13,229	1,640,988
Kentucky	84	....	41	6	4,301
Michigan	330,500	222,683,461	....	....	28,459,270
Missouri	33,096	94,452	161,016	128,589	28,086,887
Oklahoma	....	....	2,888	6,394	944,696
Wisconsin	....	....	4,413	25,927	3,188,460
Total quantity, 1910	365,702	222,777,913	171,226	178,784	....
Value, 1910	$197,479	$28,292,795	$15,067,888	$19,308,672	$62,866,732
Total quantity, 1909	301,629	234,136,529	168,221	175,337	....
Value, 1909	$156,848	$30,437,749	$14,467,006	$18,936,396	$63,997,999

San Francisco Meeting, American Institute of Mining Engineers

The San Francisco meeting of the American Institute of Mining Engineers was opened Tuesday morning, October 10, with an informal reception to the visiting delegates in the Red room of the St. Francis hotel. The morning hours were spent by the members in meeting their friends who were in San Francisco to attend the sessions of the Institute. One of the chief topics of conversation was the delightful reception extended by the Los Angeles members when the delegates' special stopped at the southern California city on the trip to San Francisco. They were met at the station on October 5 by a committee, who escorted them to the headquarters at the Alexandria hotel in trolley cars specially reserved for the delegates. All preliminary details were cared for by a committee which had boarded the train at San Bernardino several hours before. At the Alexandria the ladies' committee held an informal reception for the ladies of the party in the mezzanine parlors. In the evening the Sierra Madre Club members were hosts at a cleverly appointed dinner in their club-rooms at 313 West Third street. The spirit of the occasion was well borne out by the invitation cards, a reproduction of a placard announcing, in straggling letters,

"NOTICE.

"This is the Camp of The Sierra Madre Club. It is Open to all Mining Men & Prospectors. The Flour and Bacon are cached on the Roof and the Water Hole is just back of the Cabin. Let Those who pass on this Trail help themselves."

Below was inscribed a further greeting and welcome to the members of the Institute by the Sierra Madre Club.

The evening, however, was not wholly devoted to merely lighter matters, and a lecture on the Los Angeles aqueduct by William Mulholland, chief engineer in charge of the project, was both interesting and instructive. The lecture was illustrated with many lantern slides showing different features of the work.

On Friday, October 6, the delegates were guests on an extended trip to points of interest near Los Angeles. The oilfields, the Soldiers' Home, the Redondo power house of the Pacific Light & Power Co., and the pleasure resorts at the famous beaches clustering about the city were some of the places visited. The trip was in charge of B. L. Dowell, traveling passenger agent of the Pacific Electric Railway company. The dinner was served in the unique 'fish restaurant' of Hepburn & Terry at Redondo.

The first business session of the San Francisco meeting was called to order Tuesday afternoon, October 10. W. C. Ralston, as chairman of the local committee, in a few well chosen words welcomed the visitors, for whom Robert W. Hunt, vice-president of the Institute, responded happily in a short speech. The first official act of the delegates was the despatch of a telegram to President Kirchhoff expressing their regret at his absense, and their sympathy in his trouble, with their hopes for the prompt recovery of his mother, whose illness prevented Mr. Kirchhoff from attending the meeting.

The first paper read at the meeting, presented by E. B. Durham, was a well-prepared description of the electrolytic refining methods used in the United States Mint at San Francisco. This was followed by a paper by Bernard McDonald, who in his account of the 'Parral Tank System of Agitation,' gave a particularly interesting description of the improvements in practice he had worked out in the Mexican mills recently erected under his direction.

The geology, equipment, and method of working at Newport iron mine, Ironwood, Michigan, was described by B. W. Vallat. At this mine the sub-slicing system of mining is employed and in 307 working days in 1910 a total of 1,074,800 tons was hoisted through one shaft, an average of 3500 tons per day. The highest record was 6652 tons in one day, the average hoisting distance being 2150 ft., the maximum hoisting speed being 2200 ft. per minute, and the production was secured from four different levels. In discussion of this paper Gardner F. Williams called attention to the similarity of the mining system to that adopted at the Kimberley mine in South Africa in 1887, though at the latter no timber is used to form the top mat. The upper slice is caved as at the Newport mine, but the waste follows the ore directly. At Kimberley the hoisting is all done from one level, the material being dropped through winzes as much as 500 ft. to reach that level. There are two 10-ton skips for hoisting, these being run in balance. In separate compartments are cages for handling the 1000 natives employed. On August 4, 8514 tons was hoisted in 12 hours from the 100 ft. level, and August 11, 9098 tons. The highest previous record was 8433. In six days 48,000 tons has been hoisted. Material is brought to the loading station in one-ton cars hauled by an electric locomotive. The cars are dumped by the natives and trains of 32 cars have been handled without stopping the train which moves slowly over the bin.

In his treatise on the 'Electro Deposition of Gold and Silver from Cyanide Solution,' S. B. Christy gave a scholarly review of the work of the last dozen years on this highly technical subject. The paper contained much interesting material, but too complex to be summarized in the space available in this issue.

The technical session on Wednesday morning was opened by an intensely interesting paper on 'California Oil,' by Mark L. Requa, to which the secretary emeritus, Dr. Raymond, added pertinent and interesting discussion in which several other members joined. A representative of the Panama-Pacific Exposition welcomed the members of the Institute to San Francisco and requested their aid in making the forthcoming exposition a success. The papers on dredging by Messrs. Charles Janin and Francis J. Dennis were read by Mr. Dennis in the absence of Mr. Janin, and a brief discussion of dredging problems followed. This was followed by an interesting paper on the gold production of California, by Charles G. Yale, who has been so closely identified with the development of the mineral industry of California, and many of the members joined in the discussion which followed.

The secretary read a telegram announcing that a research scholarship would be established at Columbia University as a memorial to Samuel Franklin Emmons, as noted in the editorial pages of this issue. E. H. Benjamin announced that A. D. Foote, whom it was hoped would be present at the meeting, was undergoing a serious operation, and a resolution expressing the hopes of the members present for his safe and speedy recovery was unanimously carried. The morning session was brought to a close by an informal talk by Thomas T. Read on the mineral industry of China, illustrated by lantern slides, which aroused much interest.

At 2 p.m. Wednesday afternoon the party left the City by special train for a trip down the peninsula and a visit to Stanford University. At Palo Alto they were met by the Stanford members of the Institute and the students in mining, and taken by special cars and autos across the beautiful campus of the University. The shops, laboratories, libraries, and museums were inspected, after which on the roomy porches of the Delta Upsilon house the visitors were served light refreshment and informally met the men of the departments related to mining. The return to the City was uneventful and the party scattered for the evening with grateful memories of a memorable afternoon among the tall trees and in the quadrangles.

In a paper on the 'Fritz Engineering and the Coxe Mining Laboratories of Lehigh University,' Joseph Daniels, associate professor of mining engineering in that institution, on Thursday morning told of the founding and equipment of the two laboratories. He remarked that the new ore-dressing laboratories of Lehigh are in the nature of a new departure, as, on account of its proximity to the Pennsylvania coalfields, the principal interest of the university has been in coal mining. With the new facilities it has been found that in spite of the fact that 90% of the students are drawn from coal-mining districts, only 10% of the students after graduation return to the coal-mining industry, the majority preferring metalliferous mining. R. W. Hunt, who was chairman, spoke at the dedication of the Fritz laboratory, remarked Mr. Daniels. In this laboratory, tests were made of concrete material, for the city of Scranton, and it is proposed to provide facilities for testing road material.

In a technical but intensely interesting paper on 'Slime-Filtration' George J. Young, professor of mining and metallurgy in the Mackay School of Mines, which will be presented in abstract in next week's issue, told of the data he had collected.

Reiji Kanda, a consulting engineer of Tokyo, a member of the American Institute of Mining Engineers, arrived on the *Chiyo Maru* on Thursday and spoke at the session as a representative of the Mine Owners' Association of Japan. He bespoke a warm welcome for the American engineers on their coming trip, in which he will act as escort.

A paper by H. Foster Bain, in which he advocated the leasing system of the Alaska coal-lands, and the opening of one mine by the Government, aroused some of the keenest discussion of the Institute. J. W. Malcolmson asked why it would not be advisable to permit the development of Alaska on the individualistic lines which existed during the development of the West. Mr. Bain pointed out some differences in the two problems and asserted that the men most interested in the coal-lands of Alaska were not residents there throughout the year. Edward W. Parker gave some interesting statistics regarding the consumption of coal in the United States and the production of coal in Alaska.

Dr. R. W. Raymond, who was acting as chairman, strongly disapproved of the course advocated by Mr. Bain. He affirmed that the United States Government is not capable of conducting the fuel business with the same certainty of method as private individuals, and said that the Government has no maps which show the mineral land still the property of the United States. The aim of the Government, he continued, has been to give every man a chance to own 160 acres of coal land, and not to interfere with his disposal of the land. But the Government lately has undertaken to add commandments to the decalogue, and to create crimes for which none need blush because denounced by some demagogic reformer. The United States, he asserted, in regard to the Cunningham claims, failed in its trust in not granting title to the claims. The main feature of the new law, he said, had been disregarded, in that stockholders in one coal company could not hold stock in a rival company. In the future some 'Glavis Junior' might discover such ownership and associated stockholders would lose without appeal title in the lands. Federal taxation of any natural resources would subject citizens utilizing the resources to a handicap not experienced by the citizens of Texas, where the State of Texas and not the United States has control of natural resources. The people of the United States are drifting into a policy of opportunism, and the multiplicity of laws has made it impossible for industrious and ambitious citizens to know whether or not they are criminals under the law. We now have a lot of impossible cures for imaginary evils through recent legislation in individual States, but such legislation at least indicates that individual States can be persuaded to remedy evils, while it would be impossible to get a majority of the States to agree on any change in the Federal policy. Mr. Raymond's speech was interspersed with witty stories, and was greeted with applause.

Thursday afternoon the delegates visited the University of California. Dr. Raymond gave in the Greek theatre some 'Reminiscences of the Beginning of the Institute,' and G. T. Becker gave a biographical notice of S. F. Emmons.

On Friday many of the delegates went on an excursion to the gold dredges at Natoma. There they were entertained at a pleasant luncheon by the Natomas Consolidated company. After luncheon the dredges were visited and the rock-crushing plant at Fair Oaks inspected. On the return the delegates were guests at dinner of the San Francisco committee in the dining-car. Many of the ladies and delegates as well were visitors to many factories about the bay, where a cordial welcome was given them.

On Saturday afternoon the delegates will leave the St. Francis hotel at 1:30 p.m. in special sightseeing automobiles for a three-hour trip, stopping at Golden Gate Park to witness the ground-breaking ceremonies for the Panama-Pacific International Exposition in 1915. A number of tickets for grandstand seats have been obtained by E. H. Benjamin for distribution to the visiting delegates.

On Sunday the delegates will visit the Bohemian grove. They will have luncheon at Bohemia, and there will be a concert in the grove under the direction of Wallace A. Sabin. The party will leave the Sausalito ferry at the foot of Market street at 7:45 a.m., and will arrive at Bohemia at 11 o'clock. The return will be made at 3:15.

The following members have registered as present at the meeting at San Francisco: R. M. Atwater, Jr., W. S. Ayres, H. F. Bain, A. S. E. Beall, H. P. Bellinger, E. H. Benjamin, G. B. Berger, F. W. Bradley, S. K. Bradford, S. E. Bretherton, R. A. Bryce, Albert Burch, A. P. Busey, S. J. Cheney, S. B. Christy, W. B. Clark, Newton Cleaveland, F. G. Cottrell, J. J. Crawford, J. B. Cullan, E. S. Cunningham, F. H. Dakin, Jr., Joseph Daniels, G. M. Davidson, W. J. Davis, Jr., Courtenay De Kalb, F. J. Dennis, Francis Drake, E. T. Dumble, E. B. Durham, C. E. Dutton, H. L. Eaton, L. H. Eddy, J. B. Farish, H. C. Farnum, D. M. Folsom, D. L. H. Forbes, E. L. Foucar, G. H. Garrey, G. H. Garthwaite, J. N. Garvin, C. W. Goodale, Meade Goodloe, F. W. Griffin, C. E. Grunsky, W. R. Hamilton, A. A. Hanks, E. A. Hersam, L. Holbrook, R. W. Hunt, D. B. Huntley, J. Hutchinson, W. R. Ingalls, J. W. Ingersol, Murray Innes, Reiji Kanda, M. B. Kerr, E. B. Kimball, S. A. Knapp, J. B. Landfield, Willis Lawrence, Clement Le Boutillier, C. A. Liddell, J. J. Lincoln, Lycurgus Lindsay, Bernard MacDonald, J. W. Malcolmson, F. O. Martin, N. J. Martin, W. R. McIlvain, J. H. Means, W. W. Mein, C. W. Merrill, F. J. H. Merrill, George Mesta, R. B. Moran, F. H. Morley, T. K. Muir, W. S. Noyes, Carl Otto, T. H. Oxnam, E. W. Parker, J. B. Pierce, R. H. Postelthwaite, J. W. Pott, B. R. Putnam, R. S. Rainsford, W. C. Ralston, R. W. Raymond, T. T. Read, M. L. Requa, D. M. Riordan, G. W. Riter, Milnor Roberts, G. McM. Ross, W. L. Saunders, Gustave Schrader, H. J. Sheafe, J. M. Sherrard, L. A. Sisley, F. L. Sizer, H. P. Stow, A. M. Strong, Joseph Struthers, Edwin Thomas, F. F. Thomas, S. Tuelmin, R. C. Turner, B. W. Vallat, A. E. Vaughan, E. C. Voorheis, J. H. Weddle, J. C. West, W. H. Wiley, G. F. Williams, A. W. G. Wilson, J. S. Wilson, N. R. Wilson, W. A. Wilson, O. C. Wolf, William Wood, W. M. H. Woodward, C. G. Yale, G. J. Young.

Copper Producers Association Statement

The Copper Producers' Association September statement shows an increase during the month in accumulation in this country of 7,453,355 lb. The details are as follows.

	Pounds.
Stock of marketable copper of all kinds on hand at all points in the United States September 1, 1911	133,441,501
Stock of marketable copper of all kinds on hand and at all points in the United States October 1	140,894,856

The changes in surplus since January 1, 1911, have been as follows, in pounds:

	Increase.	Decrease.
January	20,409,295	....
February	14,198,280	....
March	5,370,164	....
April	3,547,974	....
May	440,024	....
June	....	8,561,768
July	....	19,695,306
August	....	4,297,357
September	7,453,355	....

There were 2,434,664 short tons of crude ore from Colorado sold or treated in 1910.

Discussion

Readers of the Mining and Scientific Press are invited to use this department for the discussion of technical and other matters pertaining to mining and metallurgy. The Editor welcomes the expression of views contrary to his own, believing that careful criticism is more valuable than casual compliment. Insertion of any contribution is determined by its probable interest to the readers of this journal.

Historical Notes on the Air-Lift Agitator

The Editor:

Sir—In my article entitled, 'Historical Notes on the Air-Lift Agitator,' through an error in typewriting, the cyanide consumption for electrolytic precipitation is given as $7\frac{1}{2}$ lb. This should have been $1\frac{1}{2}$ lb. The consumption now on the same slime is between $\frac{1}{2}$ and $\frac{3}{4}$ lb., the greater portion of which is mechanical loss due to crushing in water. Were the crushing done in solution, the loss would probably be between $\frac{1}{4}$ and $\frac{1}{2}$ lb., so that a consumption of $1\frac{1}{2}$ lb. without mechanical loss is obviously too high.

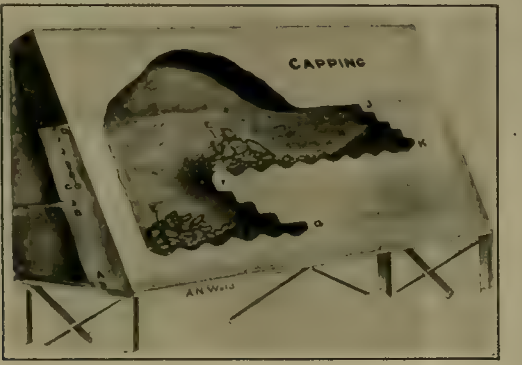
San Francisco, October 3.

Block-Caving and Sub-Stoping

The Editor:

Sir—Referring to Fred C. Roberts' paper on 'Block-Caving and Sub-Stoping' in the *Mining and Scientific Press* of September 2, I would say that I have observed these two methods in use on the Menominee Range for a number of years, and that they are safe and highly economical methods where the conditions are suitable for their application. The block-caving method can be applied to any orebody over 100 ft. in width and with sufficiently steep enclosing walls, so that the broken ore will not 'hang up' on the foot-wall. For the application of the sub-stoping method, the orebody should be, say, from 12 to 100 ft. in width; should have steep enclosing walls; should not be too soft or 'blocky', so that the benches will not break down of their own weakness; and the ore should not be too hard or the cost of driving the subs will be excessive.



MODEL OF BLOCK-CAVING AND SUB-STOPING.

I have thought so well of these methods that I have had models made to illustrate them to my classes in the Michigan College of Mines. I enclose a sketch of the model of the sub-stoping method. A ladder-way between the subs is shown from *A* to *B*, and another from *D* to *C*, on the model. From *J* to *K* the first-level subs are shown; and from *F* to *G*, the second-level subs. *H* and *H* are piles of ore lying upon the funnel-shaped chutes through which the ore is drawn off to the levels at *A* and *B*. At *E* and *E* is shown what would happen if the capping should break into the stopes. Provision could be made to take care of such falls of capping without losing much ore, either by allowing the rock to follow the ore down, or by leaving small pillars of ore to support the broken rock. In the Hiawatha mine, in the same district, pillars are left transversely across the orebody at intervals to support the capping and the hanging wall. The pillars will be mined out after the stopes are finished.

F. W. Sperr.

Houghton, Michigan, September 13.

Inadequacy of Language

The Editor:

Sir—I have read the letter from Mr. E. A. Smith appearing in your issue of August 26. Of course, I sympathize with him, for those who make the most frequent use of written language as a vehicle of thought are the most likely to appreciate the inadequacy of their medium. He quotes the sentence: "From this point to the end of the level the values are low and would not pay to treat unless the mill capacity is increased," and suggests that the word 'values' is correctly employed; then he gives two alternative versions of the above sentence with a view to proving that an academic use of terms would not be advantageous. The idea to be expressed is that the ore exposed in the level is not rich enough to yield a profit now, but that it would be profitable on a larger scale of operations. Mr. Smith insists, most properly, that the term 'ore' should be applied only to metal-bearing rock that will yield a profit at a given time and place. It appears to me, however, that the definition of 'ore' is fulfilled by the reference to the future enlargement of the mill, and that therefore it will be proper to say: "From this point to the end of the level the ore is low grade and cannot be profitable unless the cost is decreased by enlarging the capacity of the mill."

When Mr. Smith, in Mexico, was protesting against the editorial objection to a convenient colloquial term, another gentleman, Mr. W. R. Rumbold, in Northern Nigeria, was seconding the motion in the September issue of *The Mining Magazine*. To the busy man the refinements of language are a nuisance; if he can express what he means, that suffices. But the weakness of the implied argument in favor of colloquial terms is that such terms do *not* express the meaning intended, because they represent the ill-disciplined use of an instrument of precision. If 'values', as applied to ore, always meant the same thing, we who are editors would welcome a term that expressed an idea recurrent in mining affairs. But this is exactly what 'values' fails to do. At Johannesburg the managers speak of a banket seam having a 'value' of, say, 28 shillings per ton, and if the mine contains 1,000,000 tons the shareholders are apt to believe that they have assets worth £1,400,000. The 'value' of the ore, of course, is its assay-value, namely, 28s., less the cost of extraction and realization, 18s., leaving 10s. Ten shillings per ton is the value of the ore. This case is simple. Now suppose the ore to assay in gold 18s. per ton, then, with an identical cost of operation and administration, the ore would have no present value, although it contains 18s. worth of gold per ton. When 'value' is employed in a colloquial way as meaning assay-contents, it soon loses any precise significance. Thus Mr. H. A. Piper, an engineer of the highest reputation, in Rhodesia, wrote in a report that a cross-cut had "come into values, as follows: The west side assays 3.2 dwt., whereas the east side gave only 1.9 dwt., and there is practically no copper." Obviously, a small width of ore assaying from 1.9 to 3.2 dwt. per ton in gold, with traces of copper, in Rhodesia, in 1911, is worthless. The copper is enough to hinder cyanidation. The average cost of operating mines in Rhodesia at the present moment is several times greater than the assay-value of the material mentioned by Mr. Piper. The question then arises how to describe such material. We venture to suggest that Mr. Piper might have said: "The cross-cut has penetrated a lode assaying 3.2 dwt. gold on the west side and 1.9 dwt. on the east side, with traces of copper" or "The cross-cut has passed through the lode at a point where it assays 3.2 dwt. gold on one side and 1.9 dwt. on the other, but without copper." Of course, a very little copper might be a nuisance in the cyanide plant, although itself of no commercial 'value'; on the other hand, the proportion of copper required to attain 'value' would be at least several per cent, in Rhodesia, in 1911. Just as Mr. Piper's phraseology tends to exaggerate the worth of two or three pennyweights of gold, so also his "practically no copper" may fail to indicate the presence of enough of that metal to drive a cyanider to bad language of another sort. The trouble with such terms as 'values' is that they defeat the whole purpose of language. Inadequacy will surely be the mark of technical speech if we adopt slipshod colloquialisms.

Mr. Smith, in his temperate and reasonable protest, says that 'values' "conveys its meaning to the reader"; but this is what it often fails to do, not in his hands, perhaps, but assuredly in the hands of others less careful. As a loose equivalent for the assay contents of metal-bearing rock it serves no duty that cannot be better done by other terms. Surely it is of the essence of mining to distinguish between that which yields a profit and that which does not. He suggests that 'values' should be accepted as referring to "the worth of the marketable contents for a given weight or measurement of an ore deposit, without consideration of the possible profit or loss resulting from mining, treatment, or shipping costs." He means the market price of the extractable metals, without regard to the cost entailed, but he introduces the idea of worth, which is the proper abstract idea signified by 'value.' His definition is easily proved impracticable. Take such an ore as is found in the San Francisco del Oro mine, containing gold, silver, lead, copper, and zinc, in which the presence of some of the metals detracts from the value of the others to such a degree as to reduce the marketable worth of the ore to zero. The 'value,' according to Mr. Smith, might be $35 per ton, but the amount of money realizable therefrom would be nothing in Mexico in 1911.

It will have been noticed that the plural form is generally employed. Messrs. Smith and Rumbold, for example, would say that "the values are low," that 'they' disappear as the level goes northward or southward, that 'they' increase as the winze is sunk or the rise is extended to the next level, and so forth. Why not the 'value'? Because indefiniteness and comfortable vagueness is obtained by pluralizing. If several metals existed in the ore, say, both gold and silver, or copper associated with the two precious metals, it might be inferred that the reference was to the multiplicity of valuable contents; but that is not the case. 'Values' may refer to 2 dwt. of gold where the operating cost is $4, or it may suggest several conflicting metals, so that the metallurgical extraction of one or more of them is obstructed by the presence of one or more of the remainder.

Thus we come to the fundamental fact that 'value' connotes an abstract idea and that it is applied by careless writers to signify a concrete idea. Mr. Piper says that "the values appear to jump from foot-wall to the hanging-wall side," and Mr. Smith says that "the values would not pay to treat" in a mill of small capacity. It would be as intelligible to pursue a quadratic equation in an aeroplane as to "treat" 'values' that jump from one wall to another. Confusion of ideas necessarily leads to inadequacy of language.

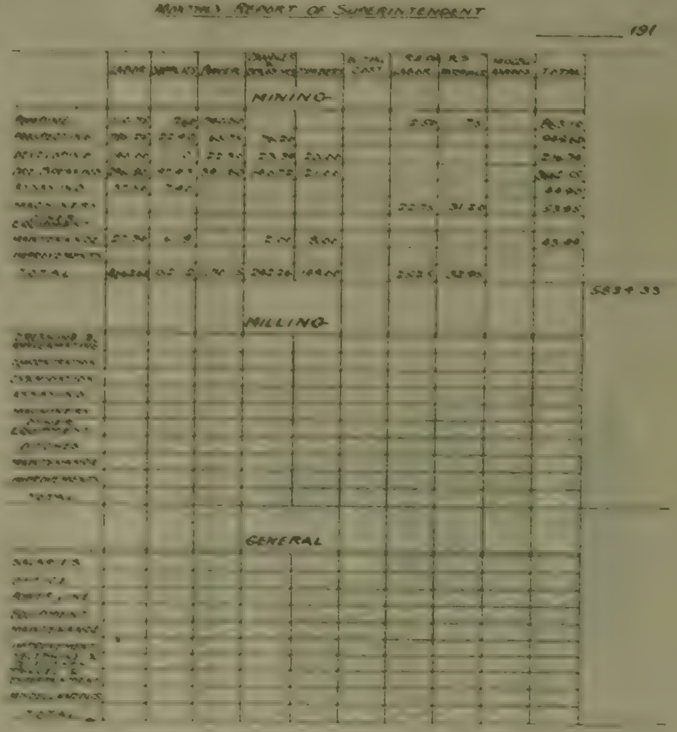
T. A. Rickard.

London, September 18.

Simple Methods of Mine Bookkeeping

The Editor:

Sir—The accompanying tabulated monthly statement has been worked out and is in use at the Gold Hill & Iowa mines. It may be of interest in connection with the discussion on mine accounts appearing from time to time in the Mining and Scientific Press. As used, it is partly of the nature of a financial report, the 'Labor' totals plus the 'Repairs-Labor' totals check with the payroll, and the grand total of the report checks with the sum of the entries on the credit side of the cash book. The expenses apportioned to mining for one month are given as an example of the working of the system. Added horizontally, the costs of the different mining operations are obtained; added vertically, the totals show the expense of labor, supplies, and power. Of course, the sum of the totals of the vertical columns checks with the sum of the totals of the horizontal columns, which in this case is $5834.33.



MONTHLY REPORT OF SUPERINTENDENT
191
MINING
TOTAL
5834 33
MILLING
GENERAL

With the expenditures thus concisely tabulated, the working out of the cost per foot of prospecting and development, and the cost per ton of mining and milling, is an easy matter, as is also the segregation of these costs. Daily record is kept of the work of each employee, and this is apportioned under 'Labor' or 'Repairs-Labor.' All bills are apportioned to the month during which they are incurred, although there are two objections to this: (1) in laying in large quantities of supplies, certain costs will appear abnormally high; (2) it is not always possible to know where the supplies will eventually be used, whether in prospecting, ore-breaking, or development. A yearly report, made up of the sum of the monthly reports, and applied to the total work done during the year, arrives at a close approximation of actual costs. By apportioning the supplies and materials actually used during the month for which the report is made, more definite data can be obtained, but with considerably more work. The only books used are the cash book and expense book. In the latter all bills are copied in full, the details being carefully noted. This enables one to look up quickly any detail of price or dimension of supplies or materials, making it easy to duplicate orders, particularly for machinery parts and extras. This system of keeping accounts has proved simple and adequate.

W. L. Bowron.

Quartzburg, Idaho, August 25.

There were 5,079,446 short tons of ore from Montana sold or treated in 1910, a decrease of 341,739 tons, or about 6%. The production of copper ores, which amounted to nearly 90% of the total tonnage treated, declined 448,684 tons. Only 266,689 tons were treated in gold and silver mills, and 616,596 tons were shipped crude to smelters, but 4,170,124 tons, or 82% of all ore treated, were sent to concentrating mills.

Concentrates

Most of these are in reply to questions received by mail Our readers are invited to ask questions and give information dealing with the practice of mining, milling, and smelting.

BORAX GLASS is ordinary borax which has been fused to drive off its water of crystallization It is much used as a flux in assaying.

ALUNOGEN is hydrous sulphate of aluminum formed in nature by the action of the sulphuric acid of decomposing sulphides upon aluminous shales. It differs from ordinary alum, which it resembles, in containing no potassium.

POLYBASITE is a soft, iron black silver mineral of the composition $(Ag, Cu)_9SbS_6$. It frequently occurs in six sided tabular prisms and before the blowpipe fuses with spirting, giving off heavy white fumes, sometimes of a garlic odor, and yielding a silver-copper button.

TONOPAH is the Indian name for a species of grass often found growing near water holes in the desert regions of the Rocky Mountain States, and, like many other Indian names, has been adopted as the name of a place which in this case later became a noted silver-mining camp.

ELECTRIC induction furnaces for steel production have the disadvantage of not melting the slag thoroughly, as they generate their heat within the metal and the slag is always cooler than the metal, instead of hotter, as it should be. Induction furnaces are not well suited to melting down cold charges, as it is only in a molten charge that the current is readily induced.

TALC quarries are as profitable as gold mines when the product is of good quality and is found in ample supply. In 1909 about 130,000 tons of talc and soapstone were produced in the United States, having an approximate value of $10 per ton. For profitable operation a talc quarry must have excellent transportation facilities, but if on a railway line near a large city is likely to be a steady source of revenue.

QUICKSILVER production is not an especially profitable industry, though an important one. Most of the large mines in the United States treat ore of which the quicksilver content averages less than 1%. The larger part of the production comes from California, with Texas as second, and the total annual production for the United States has had a value of a little less than a million dollars per year during recent years.

SHASTA COUNTY, California, has sent out much good ore, but never furnished a 'single $3,000,000 shipment.' The story to that effect doubtless originated from the fact that during the first year of operation of the Bully Hill C. M. & S. Co., the copper made was held at the mine pending completion of the Delamar refinery at New York. When the refinery was ready the copper was shipped East as fast as cars could be obtained.

SHOSHONE COUNTY, Idaho, furnishes 99% of the lead production of that State. Practically all this lead is derived from argentiferous galena ore from the Coeur d'Alene district, occurring in fissure veins and zones in pre-Cambrian quartzite. Most of the ore is concentrated to a content of 45 to 60% lead. Idaho produces one-third of the total lead of the United States, and, with its silver production, holds an important place in the mining industry.

CRUDE PETROLEUM varies in specific gravity. In Ritchie county, West Virginia, the Prunty pool, Big Injun sand, yields an oil of 0.7701 sp. gr. A sample from the Sun pool, Hardin county, Texas, collected by David T. Day, showed a specific gravity of 0.9352. This corresponds to a variation of nearly 60 lb. in the weight of a barrel of oil. The average specific gravity of Russian crude petroleum, as taken from official reports, is 0.86, approximately, or 301 lb. per barrel.

BARREL is a term of varying significance, as it is used both as a measure of capacity and of weight. The standard oil barrel is 42 U. S. gallons, the standard beer barrel 36 gal., and the standard wine barrel $31\frac{1}{2}$ gal. When used for solid substances a barrel is a measure of weight; for example, a barrel of flour is 196 lb., and a barrel of fish, beef, or pork, 200 lb. The standards differ in some States, and it should be remembered that from their nature it is not possible to construct barrels with mathematical accuracy.

GOLD can be freed from lead in smelting zinc-box precipitate by the use of a flux containing 60% borax, 19% nitre, $11\frac{1}{2}\%$ sand, and 7% soda. Manganese dioxide is said to be more efficient than nitre in oxidizing the lead, and for fusing 100 parts of slime a flux composed of 20 to 35 parts of borax, 20 to 40 parts of manganese dioxide, and 15 to 40 parts of sand, is highly recommended. Gold recovered from alluvial work is usually nearly free from base impurities and can be melted down with a little borax glass and nitre. Fluorspar, when available, is a good flux, as it is very liquid when molten.

SULPHUR production in the United States has increased greatly during the last decade. The production in 1900 was valued at less than $100,000; the present production is over $5,000,000 worth per year. Most of this comes from Louisiana, though there are important producers in Nevada, Texas, Utah, and Wyoming, and sells for about $22 per ton. Considerable amounts of crude sulphur were formerly imported from Italy and Japan, the former country supplying the Eastern United States and the latter the Western States, but by a recent ruling of the customs authorities Japanese sulphur has been classed as a refined product and required to pay a duty of $4 per ton. Domestic production on the Pacific Coast thus will be stimulated.

CRYOLITE is one of the comparatively few useful minerals which has not yet been discovered in commercial deposits in the United States, at least not in deposits such as can compete with those furnishing the imported product. In fact, there is but one important known deposit in the world, namely, at Ivigtut, an Eskimo hamlet on the southern coast of Greenland. Even this deposit is only about three acres in extent. Cryolite is used principally in the manufacture of opaque glass, for enameling iron ware, in the metallurgy of aluminum, and as a flux in the manufacture of white portland cement. According to the U. S. Geological Survey, the imports of cryolite into the United States in 1910 amounted to 36 long tons, valued at $2343. Refined cryolite is relatively high priced, selling in carload lots at about $140 per ton.

A HALF part per million of iron in water is detectable by taste and more than 4 to 5 parts make a water unpalatable. In some mineral springs iron is the constituent which imparts a medicinal value to the water but ordinarily it is undesirable. More than 2.5 parts per million in water used for laundering makes a stain on clothes. Iron must be removed from water from which ice is made or a cloudy discolored product will result. An iron content of over 2 or 3 parts per million in water used in the manufacture of paper will stain the paper. Iron is harmful in water used for steaming, for it is in equilibrium with acids which inside the boiler become dissociated, with the result that the free acids corrode the boiler plates; but the amount of iron carried in solution by most waters is so small that the damage it does to steam boilers generally amounts to little.

Special Correspondence

DENVER, COLORADO

Pumping Project at Leadville.—Method of Finance.—Placers at Newlin Gulch.—Uranium and Vanadium in Colorado.

Leadville is taking another active step in the work of rejuvenating herself. A project has been started by operators which, if successfully consummated, as now seems likely, will render large bodies of ore now under water available for mining. This enterprise has in view the unwatering of the entire 'downtown' sections; also Fryer and Carbonate hills, by means of large-capacity pumping plants. The down-town mines in Leadville were closed late in 1907, when the low metal prices and high pumping costs made mining operations practically unprofitable. Until recently little attempt was made to reopen them. The present agitation for unwatering the properties seems to have been started by officials of the Central Colorado Power Co. The enterprise is backed, however, by the foremost operators and business men of the city; there probably will be no trouble in raising the necessary funds for the project.

The scheme embraces plans for the installation of two pumping plants, one to be a permanent one and the other a sinking plant. A stock company is to be formed, the major portion of the stock of which will likely be subscribed for by the power company. Shares will be sold to mine operators and other business men. It will be the aim of the pumping company to make a reasonable profit from its operations from which to pay interest to the stockholders. For draining the town section and lower Fryer hill, a pumping-plant will be installed in the Penrose shaft, according to the plans. This is the deepest shaft, being down 930 ft., and is believed to be the key to the situation. Carbonate hill will be drained by another pumping-plant, to be placed either in the Greenback or Pyrenees shaft. A huge granite dike between Carbonate hill and the town area prevents the draining of both sections from the Penrose shaft. J. W. Finch and C. S. Thomas, Jr., have examined the enterprise and think it entirely feasible. Their report further states that there are unquestionably large bodies of ore now under water.

The town area alone is said to be capable of producing 1000 tons of good ore per day and giving employment to 500 or 600 men. This estimate is based on what was being produced at the time of closing four years ago. The pumping expenses will be paid for by a tax based on net smelter returns on all ore coming from the mines benefited. This matter is to be determined by mutual agreement among the operators affected. Among the properties which will be drained in this way are the Penrose, Bon Air, Coronado, Midas, Grey Eagle, and the Nicholson mines. The finding of good carbonate of zinc ore on the dump of the Penrose and others of these mines lately has added further inducement to the putting of this project under way at an early date.

A company composed of Denver men has been formed to exploit the old Newlin Gulch placers, 35 miles southeast of Denver. These placers were the scene of the first gold discoveries in Colorado, and have been worked intermittently in a small way since their discovery in 1858. The company controls 300 acres of ground by lease and ownership, and engineers have spent some time in exploration. The yardage of pay-dirt is claimed to be sufficient to warrant the installation of a steam-shovel, or possibly a dredge, which it is expected will be on the ground early in the spring. Near the head of Newlin gulch a porphyry dike has been traced across the country, and this is believed to be the source of the gold which has been found in Newlin gulch and Cherry creek. In places the gravel runs unusually high, assays running anywhere from 40c. to $54 per yard; according to estimates of the engineers the average is over $1 per yard. The average depth of the pay-streak is estimated at 6 ft. for the entire area.

It is reported that vanadium and uranium have been found in Montrose and Rio Blanco counties. Regular shipments of carnotite ore, containing uranium, vanadium, and gold, are being made from San Miguel county to Liverpool and other foreign centres, but the companies now operating give out no information. In 1910 vanadium to the value of $630,000 was produced in San Miguel county, and this year reliable operators say the production will amount to $2,000,000. The Western Chemical Co. of Buffalo, N. Y., and the Crucible Steel Co. have purchased and are developing vanadium claims in this section. The Primos Chemical Co. is enlarging its plant at Newmire and is shipping vanadium concentrate to Primos, Pennsylvania.

Mine operators at Creede, after persistent efforts, have secured substantial reductions in ore-treatment rates from the American Smelting & Refining Co. and similar concessions in freight rates from the Denver & Rio Grande railroad. As a consequence, work in old properties there has been greatly stimulated. The Creede Local Leasing Co. has been formed, backed by Denver and Creede capitalists, and has taken leases on the Creede United, Park Regent, and other properties, which are again being actively developed. The same concern has leased the 250-ton milling plant of the Creede United company for ten years, paying a royalty of 40c. per ton for its use. The Amethyst mine is now solely in the hands of lessees. The Commodore is shipping 1000 tons per month, and the entire dump of the Last Chance mine is being milled.

KETCHIKAN, ALASKA

Renewed Confidence in Government Administration.—Reconstruction of Hedley Smelter.—Development at Jumbo.—Progress at Dolomi.

With the advent of the winter rains work at a number of mines in the Ketchikan district has been somewhat curtailed, though the visit of the Secretary of the Interior and the Director of the Bureau of Mines to Alaska is expected to pave the way for legislation which will result in a more liberal interpretation of the law by both the Forest Service and the General Land Office, and the consequent restoration of public confidence necessary to provide capital for the future industries of the country. Interests said to be those in control of the Granby, B. C., smelter have secured the plant at Hedley, on the east coast of Prince of Wales island, and are rebuilding the dock preparatory to remodeling the smelter in the spring. There is an abundance of water-power in the Ketchikan district, and the present plans contemplate the development of this to smelt by electricity. Bodies of high-grade magnetite ore have been opened in a number of the mines that would be tributary to this plant.

The Alaska Industrial Co., operating the Jumbo mine on the west coast of Prince of Wales island, is driving a cross-cut to the main haulage-adit that will bring the cars directly to the bunkers at mine end of the aerial tram. A station will be cut near the entrance to contain the blacksmith-shop and compressor, which will prevent the recurrence of the damage done to the plant by a heavy snowslide last spring. The company is making regular shipments of chalcopyrite ore to the Tacoma smelter.

On Kasaan bay development is being carried forward on the Rush and Brown, It, and Mt. Andrew properties, though the death of Samuel Lichtenstadter, president of the Mt. Andrew Iron & Copper Mining Co., has somewhat unsettled the policy at the latter. The Princeton Mining & Milling Co. is developing its property at Dolomi from which a number of shipments of high-grade gold ore have been made, and the Lon De Van on Georges inlet is driving a cross-cut adit to open several veins which are exposed on the surface of the property. The assessment work on several of the claims near Hollis will be carried on this winter in order that the ore may be sledded to tidewater over the snow. After a short time now the winter trails will be open, and as in the case just mentioned, the winter snows make interior points easier of access, instead of more difficult.

NEW YORK

REACTIONARY ATTITUDE OF WALL STREET. COPPER SITUATION. TENNESSEE COPPER AND GIROUX. PROGRESS AT GRANBY. REPORT ON RAY CENTRAL.

Wall Street is going through an unusual experience, feeling somewhat uncertainly for solid ground. The fiercest of the storm which broke upon the Street some three weeks ago, seems to have been weathered and the natural lull has come, but does not bring with it any noticeable return of confidence. Wall Street, in many ways, much resembles the late Billy Baxter, whose letters were widely read a few years since. Billy was lamenting his inability to keep abreast of events, and as an illustration declared that "when fifteen thousand people know something about a married lady my number is 14,999 and the injured husband 15,000." Wall Street has never really believed that genuine corporate regulation could be brought about, and its number is now 14,999 as to what is in the mind of the American public, and particularly as to the uncompromising attitude which that public has taken. Wall Street is now the only place in the country that holds high finance in any esteem, and it stubbornly refuses to accept as real the revolution through which the country is passing. There must ensue a period of readjustment in which material progress will be slow and sure and during which, unless cause and effect sever their usual relations, Wall Street's influence will be a diminished factor.

Copper is affected more by the conditions prevailing than any other branch of the mining industry and the dominant factor for the time is the German financial outlook. The Fatherland has been riding on the crest of the wave of industrial expansion, and its position is especially precarious in view of the disturbed conditions prevailing abroad. Germany has been using 33,000,000 lb. of copper per month, an amount nearly equivalent to 30% of our own output. It is not hard to realize therefore that copper producers are much interested in Germany's continued progress. Any industrial smash in that country would allow the surplus to accumulate rapidly, for a time at least. September's production is not expected to reach a high figure, but buying has been slow and prices depressed. Some copper has been offered as low as $12\frac{1}{4}$c., and the increase in surplus, nearly 7,500,000 lb., was much greater than had been expected. The complete domination of the porphyries becomes continually more apparent. At the Ray Consolidated, estimated costs are already being attained and lowered. The concentrator is now handling 3200 tons per day, the product going to Aguascalientes for treatment. The cost-sheet demonstrates that when the plant at Hayden is completed and all the sections of the concentrator in operation, copper can be produced well under 9c., the figure which has been used in all estimates. This will mean some 70,000,000 lb. of copper or more that can, if necessary, be sold considerably below present low prices and show a respectable profit.

While Tennessee Copper officially mentions its output of sulphuric acid as a by-product, it is nearly true that the metal is the by-product rather than the acid. The sulphuric acid plant is now turning out 500 tons per day and, with the advent of winter weather with lower temperatures, the full capacity of 650 tons per day will be reached. The copper output is about 1,000,000 lb. per month, and prospects have so far improved, by reason of the success of the acid plant, that it is expected that there will be an extra dividend in the near future and that regular quarterly dividends of $1 will be paid next year. Among the developing coppers, Giroux remains a vexatious riddle; equipped with what is said to be one of the finest 5-compartment shafts in the world, with stations built of concrete and roofed with steel beams; it is impossible to get any details as to ore development wholly or in part. It is now said that the porphyry ground has proved a disappointment. Some nine million tons of ore has been proved by drill work, but it is so scattered that it is doubtful whether it can be worked at any profit. Giroux has a large public, and the management would do much to allay the uncertainty of the shareholders if the reticent attitude were dropped and a frank detailed statement of underground conditions made.

Tuolumne, which stands out in the list of Butte copper mines as turning out the richest ore in the district, at the quarterly meeting, October 2, passed its November dividend. Market movements showed that the action was anticipated and there was a quick break in the stock. Later in the week there was a quite evident attempt to drive in a supposed short interest and the stock was bid up to $3\frac{7}{8}$, against a ruling price of $3\frac{3}{8}$ prevailing for some weeks before there was any talk of non-payment of the November dividend. The activity in Tuolumne was the feature of the copper list in the open market. The reorganization plans of the Arizona Commercial are being carried along slowly. The joint meeting of the shareholders and the bondholders held this week in Boston ratified the plan for independent reorganization in the form of a new corporation with 300,000 shares of stock, with an assessment of $3 per share. The plan as authorized is to go into effect when three-quarters of the outstanding bonds are deposited and underwriters shall have been found for the assessment.

At the annual meeting of the stockholders of the Granby Consolidated Mining, Smelting & Power Co., Ltd., held this week, E. T. Earle, A. C. Flumerfield, and William A. Payne were elected directors to succeed William A. Nash, Edward R. Nichols, and William Hamlin. The manager's report presented at the meeting had a decidedly hopeful tone. The strike in the coalfields is preventing any production, but the cost-sheet is said to show material reductions, while the purchase and development of the Hidden Creek property is stated to practically double the company's ore reserves. The expenditure of one million dollars for smelter, docks, and other equipment is said to be necessary to bring this mine to the point of profitable production, but an output of 2000 tons per day is possible before the end of 1912 if ample financing can be provided. As yet nothing definite has been determined upon in this direction. The Granby is reaching out for other new mines and bonded the Copper Queen mine, in Stevens county, Washington, near Chewalah. The property consists of six claims and the ores are said to be particularly useful as fluxes.

HIDDEN CREEK MINE.

Ray Central, one of the properties at Kelvin, Arizona, and formerly known as the Kelvin-Calumet is to be equipped with a mill. The property was at one time under option to the General Development Co. and was made one of the features of the copper list in New York. There was a great deal of adverse comment when the Development company, acting upon the recommendation of J. Parke Channing, announced that it would not exercise its option. Marketwise, the issue has never recovered. Frank H. Probert has recently made a report covering the work done up to September 1 last. Developed ore is estimated 7,848,000 tons, averaging 2.51% copper, of which there is something over half a million tons of high-grade ore of 5.83% copper. It is now proposed to expend $1,500,000 in preparing the ground for extraction and in erecting a mill with other necessary equipment.

Aside from the copper shares, the re-awakening of Tonopah is the centre of much interest, especially in Philadelphia, where Tonopah issues are much more largely held than in New York. The transferring of the leadership of the camp from the old Tonopah Mining Co. to the Tonopah Belmont and the evident possibilities of some of the developed properties of the camp has brought back into the market a considerable number of the former multitude that were interested in Tonopah and Goldfield issues. So far as public interest is concerned Porcupine seems to have passed into history as another exploded Canadian gold excitement. The Hollinger is promising to erect a mill and to be producing by July 1912. The Porcupine Gold Mines Co. is ordering a 100-ton mill. There are occasional desultory reports of rich veins, or surface finds, but as a whole the district appears to be decidedly on the wane. The Mines Company of America, which operates the Dolores, the La Dura, the Creston-Colorada, and the El Rayo mines in Mexico, cut its dividend rate from 9 to 6% at its last quarterly meeting. The disbursements were absorbing nearly the whole of the net earnings.

LONDON

Electric Smelting in Sweden.—Treatment of Complex Sulphides.—Results of Operations.—Anchor Tin Mine.—Government Aid for Mine.

One of the most interesting new ventures undertaken in England recently is a company called the Hydraulic Power & Smelting Co. that has been formed to acquire processes and works in Norway and Sweden in connection with the electric smelting of complex ores. These countries have unrivaled sources of water power. Their high waterfalls, and their low waterfalls with tremendous volumes of current, are equally applicable to the production of hydro-electric power on a large scale and at a low cost. Many of these falls are used in providing electric light, heat, and telephone current, and these modern facilities are in wide use on the Scandinavian peninsula. The power is also used in connection with steel-making. During the last two or three years the falls at Sarpsborg and Trollhättan have been employed in connection with the treatment of complex sulphides of zinc, lead, and copper. At both of these installations the electric current is bought from supply companies that have generating stations at low falls. Sarpsborg is at the south of Norway, not far from the Swedish border, and the power station is near the mouth of the Glommen river, which rises in the Dovre Fjeld not far from Trondhjem. Thollhättan is on the river Göta, which runs from Venern lake to the sea at Göteborg. At these two smelting works much experimenting has been done, but many and extensive improvements have yet to be made, for not only are the works badly laid out, but the furnaces themselves are not built of the right material. In addition to these mechanical details, the metallurgical operations require much close study before real efficiency can be claimed. The cost of the electric power is still too high, being from 30 to 40 shillings per horse-power-year.

The English company has also taken over the water rights at Tysse near Odde on the Hardanger Fjord. Here the water-power will be obtained at high head from lakes far above in the mountains. Already one of the carbide companies has a large installation here. It is estimated that the electric power will be obtainable for the extraordinarily low cost of 14 shillings per horse-power-year. The Swedish owners of the Sarpsborg and Trollhättan works have been experimenting on local ores containing finely intermixed sulphides that could not possibly be separated by water or oil, and have also tried similar ores from the San Francisco del Oro at Parral, Mexico, the Terra Nova, in Newfoundland, and slime from Broken Hill. The list of supporters of the London scheme contains many well-known names. Many of the Broken Hill people, such as the Sulphide Corporation and the North and South Mines, the Consolidated Gold Fields of South Africa, the Exploration Company, Percy Tarbutt & Co., the Rothschilds, and hosts of other important people, are in it, and capital has been subscribed on a large scale. Up to now no public issue has been made and practically nothing has been written on the subject. F. W. Harbord, the authority on steel and electric smelting, spent two months recently on the spot investigating the furnaces and the process.

The Trollhättan works are more modern than the Sarpsborg, and they contain 11 furnaces, each capable of treating nearly 3 tons of roasted sulphide per 24 hours. The horse-power used for each furnace is 350, and the energy used per ton of roasted ore is about 2000 kilowatt-hours. The heat is generated by resistance. Most of the zinc and some of the lead is distilled off, and of this about two-thirds is condensed as a crude zinc with high lead content, and the rest forms metallic powder and oxide. The crude zinc is refined in another electric furnace and an unusually pure zinc is produced assaying 99.9% and commanding a premium price. The fume and oxide goes back to a subsequent charge. Most of the lead and silver of the ore is reduced to metal and is tapped, while any copper and iron present forms a matte which carries some lead, zinc, and silver. Some lead is lost in the slag. Skimmings are also obtained containing zinc, lead, and silver. One of the curious points about the process is that the furnace is built of porous brick, evidently of texture similar to the old-fashioned zinc retorts, so that lead and silver oozes through and has to be caught in special vessels or dug out of the ground. Some modification of this structure will have to be introduced to prevent this leakage. The recovery of all the metals from these various products is a task of no great simplicity, and up to the present time the total recovery on Broken Hill slime is less than 70%. The formation of so much powder is a decided drawback. There are, however, a great many improvements already obvious, and the eminent and powerful men at the back of the scheme may be depended on to bring the process to eventual success.

I have written a great deal about Cornish tin recently, but this week I wish to draw attention to a Tasmania venture, financed in London, that is notable because it manages to keep going on extraordinarily low-grade tin ore. This is the Anchor company, which has been working a granite stockwork at Lottah in the northeast corner of the island since 1895. The extraction is about 3⅓ lb. of black tin per ton, averaging 70% metal, and the cost of mining, concentrating, and smelting is about 3s. 6d. per ton. The smelting is done by the Mount Bischoff company at the Launceston smelting works. The company has 100 stamps, the capacity of which is 4 tons per day, so that the normal output of ore is about 150,000 tons per year. During recent years, the work has been greatly impeded by drought, and for the past two years the average number of stamps running has been from 60 to 70. At times the mill has been entirely idle for months on end, and then the men would drift away to other centres. Consequently, when the water-supply became normal once more, the labor was not at hand, so the mine and mill had to work short. The yearly output during the last two years has been just over 100,000 tons, and the production about 155 tons of concentrate. Two years ago a contract was made to work the Australian property three miles away on a profit-sharing basis. Communications between this mine and the Anchor mill were impracticable, and the company had no money wherewith to improve matters. It was impossible to raise any more capital in England, for the shareholders have never yet received any dividends, the capital has been written down, and there are as many debentures as could be floated. Eventually the Tasmanian Government came to the rescue by lending £25,000 for the purpose of building an aerial ropeway. This was completed early this year, and the ore is now being transported to the mill. Writing about the scarcity of labor reminds me that this is becoming a serious question throughout Australasia. In many centres of mining, such as Broken Hill, and Mount Lyell, the position is verging on the acute, and during the next few years general conditions are bound to change greatly from this cause.

TORONTO, CANADA

Reconstruction at Porcupine. Report on the Scottish Ontario. Financial Status of Northern Ontario Exploration Co. Nipissing Dividends. Exploration in Crown Reserve.

Work is in active progress at Porcupine, despite much delay in the forwarding of machinery and material. At the Dome the work of reconstruction is being hastened by a force of 200 men. It was anticipated that the stamp-mill would be in operation by January next, but as orders for steel cannot be filled for some time, the winter will probably be pretty well over before it is in working order. Diamond drilling to the depth of 600 ft. has shown good gold contents. The plant of the Dome Extension is being rapidly set up and will shortly be in operation. The West Dome has been working for the past fortnight, and prospecting work is being vigorously undertaken. The Rea mine has the deepest shaft in camp, being down 260 ft., which is connected at the 200 ft. level with No. 2 shaft, 175 ft. distant. Underground work is being carried on steadily with a 12-drill compressor. The Scottish-Ontario has completed 800 ft. of underground work. Messrs. Dempster and Thornton, of the Forest-McArthur Engineering Co., have just completed a voluminous report on the mine which has been sent to the headquarters of the syndicate in Glasgow. Should it be regarded as satisfactory, $500,000 will be expended. The McIntyre wil shortly install a mill. The number of stamps has not as yet been decided on. Five shafts are going down, and good ore is being mined on the 100-ft. level of No. 4, where the vein has been opened up for 200 feet.

At the Plenaurum, formerly the Armstrong-Booth, the main shaft has reached a depth of 50 ft. A compressor plant has been ordered. Diamond-drilling at the Pearl Lake has proved the continuance of the vein at 925 ft. Important discoveries have been made in the sulphides with high gold content. The Three Nations Mining Co., operating eight claims, is installing a 4-drill compressor plant and boiler. The Swastika's new plant has been installed, including a 12-drill compressor. John Reddington is in charge. At the Miller, west of the Scottish-Ontario, where a vein has been found at 48 ft., core-drilling is being undertaken. In response to numerous requests for information, the Northern Ontario Exploration Co., a Bewick-Moreing flotation, has made an official statement to the effect that there have been issued 119,425 shares of £1 each of the company's capital, with options outstanding on the remaining 280,575 shares. The company still owns 6000 shares of Hollinger stock, together with 165,908 shares of Ontario Porcupine Development fully paid, with smaller amounts partly paid for, and has cash in hand approximately amounting to $425,000.

The Nipissing has declared its usual quarterly dividend of 5% and 2½% bonus. The report showed that on September 16 the company had a total of cash in hand, ore in transit, and ore ready for shipment of $1,250,000. In pursuance of the policy of determining the value at depth, a winze has been put down 346 ft. from the 275-ft. level on vein No. 64, but further progress has been delayed by water, rendering it necessary to order a battery of pumps to keep the workings dry. The orebody continues to show good silver contents at the depth reached. The Crown Reserve has also started to prove the mine at depth and has put a winze down from the 300-ft. level, which is down 165 ft. farther. It will be sunk for another 100 ft. and driving started at that level. A discouraging report has been presented by the Kerr Lake Mining Co. showing a deficit of $400,621 for the fiscal year ended August 30. The cash on hand amounted to $400,621, mining property $55,000, and total assets over liabilities $588,978. John Seward, the manager, stated that he did not feel warranted in presenting an estimate of the ore developed on account of the irregularity of the deposits. Portions of the mine formerly regarded as ore bearing had proved practically barren, whereas other areas from which nothing was expected had yielded well.

SALT LAKE CITY, UTAH

Decline of Consolidated Mercur. Some Mining History. Bingham & Garfield Railroad in Operation. Results at Ohio Copper.—Merger of Ontario and Daly Mining Company.

The prospective passing of one of the most interesting gold mines in the world is brought out in the annual report of the Consolidated Mercur. This famous old producer is evidently on its last legs, and unless the prospecting work results in some unexpected developments in the near future, the property will undoubtedly be closed down. The mine has paid $3,330,000 in dividends, and has written important chapters in the history of cyaniding, but the report for the fiscal year ended June 30 shows that only by a scratch were operations saved from a net loss, the profits for the year, with a gross output of $550,695 gold, amounted to only $496.13. This is on a total tonnage for the year of 239,190. The ores have been steadily diminishing in quantity and quality, and the average value for the year was only $3.21, although this was brought down slightly by the mixture of 12% of old tailing. The recovery was $2.32 per ton. The expense of operation included 5558 ft. of prospecting work, at a cost of $24,484, but the results were not encouraging. For some time the mine has been operated at a close margin, because the management did not wish to throw several hundred men out of work, and was continually hoping that new ore might be developed. Efforts were made to find and purchase another mine, but nothing which was submitted came up to requirements. Consequently, the president, John Dern, says in his report that as soon as future operations begin to show a loss the property will be closed down permanently. There was a balance on hand June 30 of $84,952. This is exclusive of real estate, plant, construction accounts, and supplies in use. The Mercur mine is now a little over 25 years old, the original Mercur Gold Mining & Milling Co. having been incorporated June 7, 1890, and it has had a history fraught with romance and with important developments in the science of metallurgy. The ore was supposed to be free milling, but when it was found that it would not yield to that method of treatment, the owners at that time thought themselves lucky to 'unload' on some Easterners. The new owners, after much experimenting, scored a success. In 1900 the Consolidated Mercur was organized, taking in the Mercur and J. R. DeLamar's Golden Gate and the Brickyard properties. The ore treatmen has presented many problems, among them handling the base ores and the slime, but all of these have been worked out so that a profit would have been shown had not the grade diminished while costs of mining increased. It is still possible that new discoveries of ore may be made, but those most familiar with the property have little hope of any radical change for the better in conditions.

With its new Bingham & Garfield railroad in operation and with the Denver & Rio Grande handling its old tonnage, the Utah Copper Co. is sending more ore from mine to mill than ever before in its history. An unofficial statement is that the company's own road recently has been handling 11,000 tons per dey, while the Rio Grande has been taking care of 7500 tons. Statements emanating from officials sources place the tonnage a little less, at around 15,000 per day, but even this means a big output of copper, which will show in future statements. F. August Heinze has been spending some time in Utah recently, going over Ohio Copper affairs. It is stated that the property is now earning around $20,000 per month net and that the amount will be increased when the new crushing equipment is installed.

The stockholders of the Daly Mining Co., at an adjourned meeting, voted to ratify the proposed merger with the Ontario, a 300,000-share corporation being formed to take over both of these Park City properties. The Daly stockholders are to receive one share in the new company for two in the old, a total of 75,000 shares out of the 300,000. Ontario stockholders are to receive share for share. This will leave in the treasury of the consolidated company 75,000 shares of stock, and about $135,000 in cash.

General Mining News

ALASKA

Prince William Sound

B. F. Millard has taken an option on a group of claims near the Valdez glacier, state reports from Valdez, and will start development work at once.

The Tanana

Much land in the Kantishna district has been staked out. John Lee and Andrew Ness recently filed 64 association claims covering 160 acres each.

Paul Polson, state reports from Fairbanks, on his return from the Kuskokwim, said that ore had been found in that district which paid $35 'to the shovel.' About 50 men were working there.

Walter Fisher and Collon McGillivrey have obtained a 5-year lease on the extension of the Newsboy vein, owned jointly by the Newsboy company and Stiepovich & Baker.

Fourteen miners were entombed at a depth of 170 ft. by a cave-in in the shaft of the Shakespeare claim on Dome creek. The accident occurred September 27.

ARIZONA

Cochise County

The report of the Shattuck-Arizona Copper Co. for the year ended August 1 shows that the company produced in 1911 up to the time in June when smelter shipments were suspended, 4,111,000 lb. of copper, which was sold for an average price of 12.51c. per pound. The output for the calendar year 1910 was 14,751,000 lb. of copper. The company is spending about $5000 per month in development work and probably will not resume shipments until the price of copper advances, excepting for ore removed in connection with the development work. It is believed that this ore will pay for the work. The net profit for the year was $396,687, against $757,782 for the period May 1, 1909, to July 31, 1910. The company will build a $450,000 smelter with two furnaces, each of 400 tons per day. The smelter is to be built at Douglas. The discovery of 17c. copper ore on the 500-ft. level, toward the extreme east end of the property has caused satisfaction among the stockholders.

Gila County

(Special Correspondence.)—W. H. Aldridge, managing director for the Inspiration Copper Co., said recently: "We have decided that before beginning the construction of the mill of 5000 tons daily capacity we will try out in the experimental mill the new flow-sheet proposed by Mr. Callow. This will be on a scale equivalent to one-sixth of a section of the proposed new mill, or about 150 tons daily capacity. During this time work will continue on the plans and specifications of the large mill and other surface equipment." In accordance with the above policy, the experimental mill is now being altered and enlarged. The gauge of the track in the main adit is being changed from 18 to 30 in. preparatory to ore extraction. It is estimated that 4,500,000 tons of ore can be mined through this adit. A tank for the treatment of mine timbers with zinc chloride is being erected at the mouth of the adit. Surveys for pumping stations, reservoirs, and pipe-lines are in progress at Wheatfields and at the Inspiration ranch.

The Keystone Copper Co., whose property lies between Inspiration on the east and Live Oak on the west, is operating one churn-drill on hole No. 38, about 500 ft. west and north of the shaft. This is the only work going on at present. When questioned as to the future policy of the Keystone, J. Parke Channing said recently: "There is no intention to do any mining at the present price of copper. Exploration work will go on and plans for the future development and mining of the ore will be worked out, but it would be suicidal to attempt it now." The last report gave 2,000,000 tons of developed ore averaging 2.25% copper.

The mine of the Arizona Com. Copper Co. at Copper Hill, three miles east of Globe, is still idle, pending acceptance by the Arizona Commercial stockholders of the plan of consolidation recently proposed by the Superior & Boston, or, should this fail, pending the reorganization of the company. The mine is being kept free of water.

Globe, October 6.

At a meeting of the committees representing the security-holders of the Arizona Commercial Copper Co. it was finally decided to reorganize on the plan outlined at a meeting some time ago, with the added provision that the 120,000 shares to be offered to the Arizona Commercial stockholders should be underwritten.

Mohave County

(Special Correspondence.)—Interest is growing in the Secret Pass district, in the northwestern part of the county, lying along the Colorado river. While prospecting for veins the first-comers found the dikes containing free gold. These rhyolite and porphyry dikes are from 80 to 150 ft. wide, and can be traced for about six miles. On the west, or river slope of the dikes is a cement limestone which seems almost impenetrable to any mineral. The east side is called the valley slope. There are three prominent dikes of about equal size, lying parallel to each other. The Gold Road and Tom Reed mines are successful producers.

Kingman, October 7.

Pima County

Gold ore assaying from $87 to $116 per ton has been discovered on the Southern Cross claim, in the Arivaca district, owned by H. R. Bacon and A. T. Luques, according to reports from Tucson.

Pinal County

Immediate steps will be taken for the construction of a 1500-ton mill on the property of the Ray Central Copper M. Co. The mill, according to the estimate of Weed & Probert, consulting engineers to the company, will cost about $1,500,000. It is proposed to mine the rich ore first while preparing the lower-grade ore for caving, states the engineers' report on mine conditions, recently sent to stockholders.

Yuma County

John Martin and associates, owners of the Harqua Hala mine, south of Salome, hae ordered the machinery for a large cyanide plant, state press reports, to treat the tailing in the dump of the old stamp-mill. The tailing is said to average in assay $3 per ton.

CALIFORNIA

Amador County

(Special Correspondence.)—The new 500-hp. Westinghouse motor has been installed at the Argonaut, together with the attendant rope-transmission system. Hitherto water-power has been used for motive purposes, but the hoist will in future be actuated electrically. The Argonaut shaft has a depth of over 3700 ft., including the sump. The mill has forty 950-lb. stamps, crushing 200 tons per day. The stamps are divided into eight batteries, with five stamps to a battery. The ore is broken in a rock crusher before passing to the mill. From the plates the product goes to sixteen 8-ft. Frue vanners. It is rumored that the South Amador company has obtained an option on the adjoining Champion claim. The Kennedy Extension has suspended operations. This property adjoins the Argonaut on the south and a suit has been pending between the two companies over a disputed piece of territory. Rumors of a compromise are in circulation. R. S. Rainsford is manager for the Argonaut.

Jackson, October 7.

Calaveras County

(Special Correspondence.)—A bond and lease has been taken by O. Bergstrom on the Old Homestead mine, which was operated five or six years ago by the Wilbur Womble M. Co., but which closed down on account of the financial difficulties of the latter company. The mine is about three miles from Copperopolis, and Mr. Bergstrom will proceed to drive a 300-ft. adit below the old workings, which should give about a 200-ft. back of ore. The old company had about 3 ft. of $9 ore in its stopes, and if the results of the present prospecting are satisfactory, steps will be taken to construct a mill. At the Lightner pyrite mine, near Copperopolis, Messrs. Mudd, Peyton, and Elsasser are engaged in diamond drilling to explore the orebody, which is a large mass of heavy pyrite, locally containing fair amounts of chalcopyrite. It is expected that the ore will prove valuable for burning in the production of sulphuric acid.

Copperopolis, October 6.

Eldorado County

The John A. Sowell M. Co. has bought the Mt. Gregory Con. gravel mine of Porter Phillips and his associates, according to reports from Georgetown. The mine contains 120 acres of placer ground.

Plumas County

The Neocene M. Co. has decided not to resume operations at the Scales Diggings gravel mine for some time, according to despatches from Quincy, as it will be impossible to finish the restraining dam in time for the rainy season.

COPPEROPOLIS, LOOKING SOUTHEAST.

Siskiyou County

(Special Correspondence.)—C. L. Mattfeldt of San Francisco, and Lee W. Foster, of Trail creek, have taken a bond on the Beaudry-Heinzey quartz property, Fox Creek district. The option was taken on behalf of San Francisco capitalists. Edward C. Reed has concluded an examination of the Big Cliff group, on South Russian creek. The property is owned by Wintering & Osgood of Seattle, but it is understood that a strong Eastern company is planning the acquisition of the mine. The main orebody is an immense vein of low-grade ore. It is announced that operations are to be resumed at the McKein, situated near Callahan. The 100-ft. shaft will be sent 200 ft. deeper, in the hope of striking the old vein below water-level. The Michigan Salmon River Co. is arranging for a busy season. The big hydraulic elevator successfully handled the ground last season, and operations will be conducted along broader lines. At present the company is mining on Hookerfield bar. A small cyanide plant has been installed at the Orfield & Frainer property, on Somes bar. A small vein of rich quartz has been intersected. The Bonally company is reported to have entered the old channel on the Pollaz bar section of the Salmon river. The gravel is said to contain much gold. Milling ore is being stoped on two levels at the Sherwood mine, Blue Lake district. A 5-stamp mill has been installed; also a Frue vanner. About 160 tons of ore is on the dump, with a similar amount blocked out in the mine. At the Highland, near Etna, rich ore continues to be opened. Two shifts are at work.

Etna, October 7.

Tuolumne County

(Special Correspondence.) A cave in the north drift on the 400 ft. level of the Providence mine has exposed a vein of rich ore from 2 to 5 ft. wide. A body of good ore was also found on the 200-ft. level. The shaft has been cleared of obstructions and retimbered to the fourth station. This work will continue to the bottom, and at the same time preparations will be made for the extraction and milling of ore from the new rich vein. The property is owned and worked by the New Providence Gold Mining Co., John F. Bluett, of Oakland, being the president and general manager. J. Chapman is superintendent.

The Carlotta-Pennsylvania mine, one mile north of Tuolumne, was bonded this week to a new company and preparations were at once started for commencing operations. A new head-frame is being erected, and the company also will sink the Carlotta shaft 300 ft. deeper. From the bottom, 500 ft. below surface, a drift will be driven about 400 ft. to the Pennsylvania shaft, which in the meantime will be sunk to 500 feet.

The adit being driven at the Italian Camp mine, near the old Belleview, is in 250 ft., exposing an immense vein containing a large percentage of high-grade sulphide and some free gold. There is a 4-stamp prospecting mill on the property. It is reported that the gravel mining property of Messrs. Keeler, Bennett, and Bates, at Red Mountain bar, on the Tuolumne river, will shortly pass under bond to mining men operating on the Merced river. It is understood that a suction dredge will be used. The Clio mine has been unwatered and development is now in progress. The mill at the Crystalline was started October 1. A large crew of men is employed. Near Camp Relief, which is several miles from the nearest mine of note, a promising quartz claim is being developed. It is owned by J. B. Bovey, of Oakdale, and is called Good Fortune. A shaft has been sunk 47 ft., showing a strong vein of ore 4 ft. wide which assays from $2.50 to $61 per ton. Of the numerous assays made in different parts of the State the majority showed between $40 and $50 per ton. A hoist for next year's work is planned. The vein outcrops in many places within a distance of three miles.

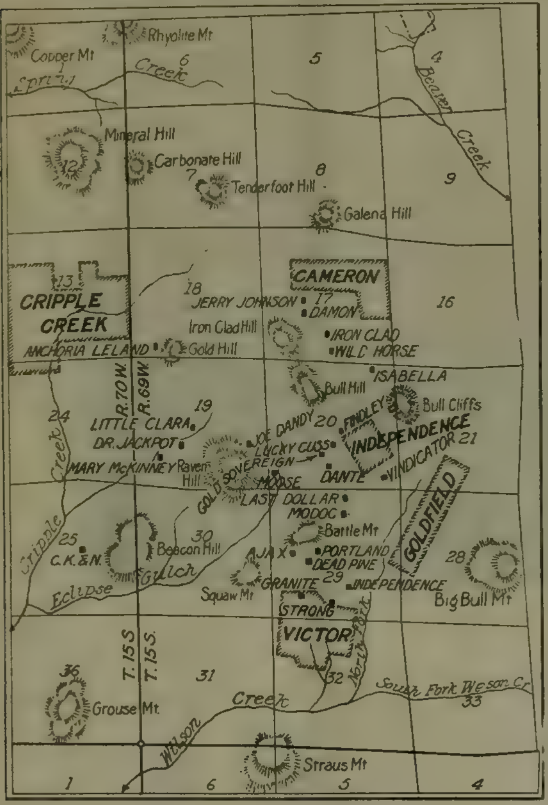
At the New Albany, one of the group owned by the United Mines Corporation, large bodies of high-grade ore are being opened and the outlook is growing better day by day. On the 925-ft. level the vein is 5 ft. wide, some of the ore going as high as $100 per ton.

Tuolumne, October 7.

COLORADO

Clear Creek County

(Special Correspondence.)—It is reported that W. E. Renshaw, representing Eastern capitalists, is negotiating the purchase of the Centennial mine on Leavenworth mountain for $125,000. A 6-in. streak of ore is reported to have been found on the New York property of the Crown Prince Con. M. Co. at Williams Forks. Frank Brady, of Empire, is manager of the mine. An 8-in. streak of heavy lead ore assaying 42% lead and 37 oz. silver per ton has been found in the breast of the Zalmingo adit on Lincoln mountain. The lower adit of Bard Creek M. Co., now in 800 ft., has intersected a vein assaying $67 per ton in gold, silver, and lead. A pipe-line has been laid from the Terrible compressor-plant on Brown mountain to the Smuggler mine to furnish air. B. C. Catren will award a contract in a few days for extending the west drift from the fourth level another 500 ft. The Dives-Pelican & Seven-Thirty M. Co. has obtained a lease on the Mendota power plant to furnish air to the Seven-Thirty and Zero mines. G. W. Tarkington is manager for the company.



MAP OF CRIPPLE CREEK DISTRICT.

Georgetown, October 9.

Gilpin County

(Special Correspondence.)—The Tucker mill has been leased to C. A. Jackson & Co. The capacity is 60 tons per day. Custom ore is being treated. Work is to be resumed on the Sleepy Hollow mine. The workings are clear of water down to the 600-ft. level. J. Tuckfield has put work under way on the Castle Rock property in Quartz Valley district. The shaft is down to a depth of 250 ft. Sinking and driving will be done.

Central City, October 7.

Gunnison County

It is reported in Crested Butte that a mill may be built by the Italian Mt. M. Co. to handle the large amount of low-grade ore already on hand. The officers of the company will visit the property in the near future. They reside in Paris, France.

Ouray County

A. Thompson, receiver for the Red Mountain Railroad M. & S. Co. has announced that work will be done on the Gold Lion and other properties.

Teller County

The Empire State claim near Cripple Creek has been blocked out and will be leased in blocks. Already eight leases have been granted.

A. J. Dell and J. Hammond, operators of the Ocean Wave claim on Battle mountain, have secured a lease on the Corolanus dump, which is said to be rich in silver.

The dumps on the Cresson property, Cripple Creek, have been leased to Denver people who will erect a 100-ton mill. The ore is said to assay from $3 to $5 per ton.

IDAHO

Idaho County

The owners of the Last Chance mine, state reports from Elk City, have purchased the Fudge 2-stamp mill at Newsome, and will erect it on their property. James P. Larsen, one of the owners, is superintendent of the property.

MONTANA

Silverbow County

(Special Correspondence.)—The official figures of the copper production of the Anaconda Copper M. Co. for the month of September shows a decrease of 1,200,000 lb. as compared with August. The figures for the past month are: Washoe smelter, 15,900,000 lb.; Great Falls smelter, 5,400,000 lb. The figures for August were: Washoe smelter, 16,000,000 lb.; Great Falls smelter, 6,500,000 lb. In these figures are included the output each month of the North Butte and Tuolumne mines. During the past month the North Butte company produced 2,100,000 lb. and the Tuolumne 500,000 lb., which would bring the actual amount of copper turned out by the Anaconda company down to 18,700,000 pounds.

It is now definitely stated that work on the Butte & Superior concentrator on the company's property will be commenced within a few weeks.

The Tuolumne company has passed its dividend on account of the heavy expense incurred in building a spur from the mine to the Butte, Anaconda & Pacific railway tracks to do away with the wagon hauling of ore and the expenditure in connection with the installation of the new surface plant. At present sinking and development work are going on on the 1000, 1200, 1400, and 1600-ft. levels and a large quantity of ore is being blocked out. On the lower level the ore will average 10% copper; the body is a large one. When sinking of the shaft was stopped several months ago a depth of 1650 ft. had been reached. It was resumed a month ago and now a depth of about 1750 ft. has been attained. When the 1800-ft. depth is reached a station will be cut and then sinking will be resumed and the shaft carried to a depth of 2000 ft., where another station will be cut. There is no decision yet as to going any deeper at the present time, although there is no doubt that early next year the shaft will be deepened by several hundred feet.

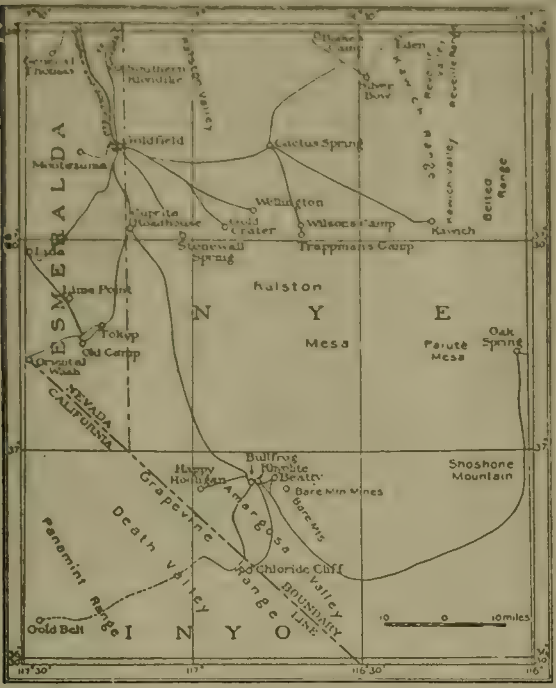
A story published in some Eastern papers to the effect that the North Butte company in cross-cutting on the vein from the 2800-ft. level had struck the Jessie vein, is absolutely without foundation. It will be in the vicinity of a week yet before the station is completed on the 2800-ft. level, and those who are figuring closely on the subject estimate that it will be at least a week and possibly two weeks after the cross-cutting is started before the vein is found.

Butte, October 9.

NEVADA

Esmeralda County

(Special Correspondence.) — Announcement was made Friday evening by J. Ross Clark, president of the Goldfield Deep Mines Co. and of the Las Vegas & Tonopah railroad, at a banquet tendered him at the Goldfield hotel by business and mining men of the district, that operations will start at once on the ground of the Goldfield Merger Mines Co., control of which has been acquired by the Deep Mines Co. L. H. Metzger, for three years past foreman of the Clermont, Red Top, and Laguna mines of the Consolidated, has been appointed general manager for the Merger Mines Co. and for the past month or more has been at Butte, Montana, making a study of hoisting equipment. He will erect a temporary hoist with sinking capacity of 350 to 400 ft., and when this depth is attained the large plant, one of the most complete and powerful in the country and with a capacity of sinking 2000 to 2400 ft., will be installed, together with compressor plant and necessary buildings to house all equipment and a monster steel head-frame. J. B. Fleming, who erected the Consolidated mill and Nevada Hills mill at Fairview, is preparing the plans for the construction of the large surface plant. Mr. Clark stated that it will probably require four months at least to complete the larger plant, but that sinking will begin at once. Mr. Metzger, the manager, has already engaged the greater part of his working force, and the work of preparation for active sinking is now in progress. A four-compartment shaft, 1500 or 2000 ft. deep, is planned. At a meeting of the Merger Mines Co. directors here it was decided to effect, arbitrarily if necessary, the final exchange of St. Ives Mining stock for that of the Merger Mines Co., of which the former is one of the components. November 6 was named as the last day upon which the St. Ives stock will be received in exchange.



MAP OF SOUTHWESTERN NEVADA.

The Florence Goldfield continues its established production of 170 tons per day, and is making a satisfactory recovery of gold from a comparatively low-grade ore.

Preliminary estimates of production by the Consolidated Mines Co. in September place the gross recovery from 26,766 dry tons at $650,000, total costs at $225,000, and net profits at $425,000. The preliminary estimates have almost invariably been well below the final returns. At the Vernal, driving is in progress at a depth of 115 ft. on the vein from which the adjoining Goldfield Belmont is extracting and shipping ore of excellent quality on its 300-ft. level.

Goldfield, October 7.

Nye County

(Special Correspondence.)—The Mineral Hill Consolidated is now in complete control of the Mineral Hill, St Paul, and Minneapolis properties, comprising nine full claims. The company will operate the leases formerly controlled by the East Side M. & L. Co., and is the only owning concern in Manhattan to operate on its own acount. The new company is controlled by San Francisco people. Alexander Hamilton, of Baker & Hamilton, is president.

Manhattan, October 7.

Storey County

The north end of the Comstock district in September produced ore valued at more than $160,000, of which the Ophir produced $94,562 and the Mexican $66,895.

C. & C. SHAFT, VIRGINIA CITY.

Washoe County

(Special Correspondence.)—The Trojan M. & M. Co. has taken a lease on the Bargo M. & M. Co.'s property and mills at Jumbo. Unwatering the mine is under way and active operation will be started in the near future. W. E. Turley, of Reno, is superintendent of the property. The post-office address of the company is Washoe.

Washoe, October 9.

White Pine County

The settling of the labor strike at the Veteran mine will not make possible the immediate resumption of work there, acording to a statement by C. B. Lakenan, general manager for the Nevada Con. Copper Co. Timbers and supplies will have to be obtained, and it will not be until the latter part of this month that ore shipments will be commenced.

NEW MEXICO

Socorro County

(Special Correspondence.)—A considerable flow of water was found in the face of the main drainage and transportation adit of the Oaks Co., and it is now thought that this bore will furnish more than sufficient water to supply the central milling plant to be built near the portal. Arrangements have been completed for the operation of the Pacific mine, adjoining the Confidence on the north.

Another contract for 2500 cords of wood was recently let by the Socorro mines to fortify against possible shortage prior to the completion of their high-compression oil-engine plant, work on which is under way. The final equipment for the latter will not be received until February.

A contract has been let to drive 300 ft. south on the 300-ft. level of the Deadwood mines, in the face of which a fine grade of milling ore is exposed. The mill is running steadily.

Mogollon, October 7.

OREGON

Baker County

The Ben Harrison M. Co. has made its second payment of $10,000 on the Ben Harrison mine. The price is $40,000, of which half has been paid. Further sinking will be done to a depth of 300 ft., when a mill will be erected.

Curry County

A No. 3 giant and 10-in. pipe have been ordered by the Winkle Bar M. & D. Co. A 4-ft. ditch, about one and half miles long, has been completed and it is believed that this will give plenty of water for mining from January to the end of May. The property is on Rogue river and is reached by going over a mountain trail. It is twenty miles from Dotham. R. G. McDonald, of Seattle, is secretary and treasurer of the company.

JOSEPHINE COUNTY

George E. Sanders, manager for the Chicago-Rogue River company, has purchased the Old Channel mine in the Galice district. The Old Channel mine is a large low-grade placer property with valuable water-rights and many miles of ditches and flumes, according to press reports, and when in operation employs a large force nine months of the year. Mr. Sanders will start work in the near future. He is now in Chicago.

UTAH

JUAB COUNTY

The Centennial-Eureka M. Co. paid a dividend of $3 per share on September 30. A similar dividend was paid last April. The United States S. R. & M. Co. owns 99,864 of the 100,000 shares of the Centennial-Eureka company, which since its organization in 1906, has paid dividends amounting to $33 per share. Two $3 dividends were paid last year.

The Opex Con. M. Co.'s report for the year ended September 30 shows that $254,449 was spent during the year. Part of the expenditure was on cross-cuts driven for neighboring companies, on contract, for which $33,667 was received. Five assessments were made during the year, from which $132,000 was received. Thus far the prospecting done has not found the vein within the Opex limits, although hopes are held that more efforts may be successful. While there was an overdraft of $5251, it is believed that if the balance of the assessment is paid there will be about $1500 in the treasury. The salary of the general manager is reported to be $15,000. At the annual meeting in Provo, Jesse Knight was re-elected president.

The Gemini M. Co. has paid a dividend of $6 per share, its first since August 1907. The present payment makes a total of over $2,000,000 paid in dividends. The company is planning to buy a new pumping plant, preparatory to deep mining.

SALT LAKE COUNTY

The Utah Con. M. Co. has declared a dividend of 50c. per share payable November 14 to stockholders of record October 21. This is the first dividend since January 1910, when decreased reserves and earnings stopped returns to stockholders. Roscoe H. Channing, consulting engineer for the company, was elected president. The company ships its copper ores to the International S. & R. plant at Tooele, and when the latter company is prepared to do lead smelting, will ship from the lead ore already already developed on the property. The annual meeting of the company was held October 7.

TOOELE COUNTY

The gross value of the gold produced by the Con. Mercur G. M. Co. in the year ended June 30, acording to the annual report recently issued, was $550,695. With dividends from the Gold Water Belt Co., ground rent, sale of base bullion, and money from other sources, the gross receipts of the company were $558,629. Operating expenses amounted to $558,133, the net profit being $496. The total assets are $85,112. The Mercur mine, originally operated by the Mercur G. M. & M. Co., organized in 1890, is about exhausted. In accordance with a plan formed a year ago to find a new mine so that the company need not go out of existence, several properties have been inspected, but none hsa been purchased.

WASHINGTON

FERRY COUNTY

(Special Correspondence.)—The Ben Hur Leasing Co. has sunk the Ben Hur shaft 74 ft. below the 300-ft. level and plans to have it down and timbered to the 400-ft. level by September 12.

On the 400-ft. level of the Quilp mine a stope 9 ft. wide is yielding ore that assays about $45 per ton. From the vein on the 500-ft. level the ore during the past week has not been as good as usual, the shipments having averaged only about $40 per ton.

The Republic Mines Corporation has been mining ore on the 300-ft. level of the Surprise mine the past week that averaged about $22 per ton in the south drift and raise and better than $80 per ton in the north drift.

The Imperator-Quilp M. Co. is building a new blacksmith and machine-shop; the one formerly used is to be made into the miners' changing room.

Republic, October 7.

H. J. Lefevre of Spokane acquired the Keller & Indiana smelter and sawmill at Keller, for $2686.60 at a sheriff's sale recently. The property has been valued at $250,000. The smelter, which is of 150 tons, and the water-power available, will be of advantage to the Keller mines, of which Mr. Lefevre is one of the owners. Mr. Lefevre also secured several hundred tons of ore and 60 tons of coke now at the smelter. Repairs on the plant will be made at once.

STEVENS COUNTY

The Granby Con. M. S. & P. Co. has bonded the Copper Queen mine, in Chewelah camp, for $400,000 and will erect bunk and boarding-houses and office rooms and will employ a large force of men on the property.

A contract has been let to drive 200 ft. of the lower adit on the Chickamun group, in Orient district, owned by the Michigan M. Co. Work has been suspended on the Alice E. mine.

CANADA

ONTARIO

(Special Correspondence.)—A meeting of the directors of the Porcupine Gold Mines Company was held in New York yesterday. The secretary of the company announced that sufficient treasury stock had been sold to provide ample funds for thorough mine development and the construction of a 100-ton mill.

The manager of the company was instructed by wire to rush the delivery and construction of the mill. The secretary also stated that all outstanding indebtedness of the company had been fully paid.

John M. Godfrey of Toronto, who represents the original owners of the Vipond mine, was elected to the Board.

Porcupine, October 4.

The Pearl Lake M. Co. is planning to sink a 3-compartment shaft to a depth of 600 ft., according to late reports. Four mineralized zones were discovered in a 900-ft. hole made with a diamond-drill. At the 400-ft. level dark schist mixed with quartz, assaying $21 per ton, was found. Above that level ore assaying as high as $58 per ton was found with the diamond-drill.

MEXICO

CHIHUAHUA

The Tajo mine will be reopened October 15 by the Arizona-Parral M. Co., state reports from Parral. H. H. Utely is manager of the property.

An electric hoist is to be erected at the Eureka mine, near Parral, and other improvements will be made. Development will be rushed in the Providencia mine, where high-grade ore recently was found. Work also will be resumed on the 23rd of July property. Edmund Putnam, of Parral, is in charge of the mines.

Work will be resumed in the near future at the Iberia mine, according to reports following a meeting of the company in charge at Jiminez recently. The mine has not been operated for some time.

(Special Correspondence.)—The Rio Plata M. Co. in August received a net return on shipments of $38,714. The stamp-mill crushed 1110 tons of ore, from which 43,636 oz. of silver was obtained, and 14 tons of concentrate. The cyanide plant treated 1783 tons of tailing, which contained 62,087 oz. of silver. The operating profit was $23,560. Expenditures on development amount to $834.

Chihuahua, October 5.

Decisions Relating to Mining

Specially reported for the MINING AND SCIENTIFIC PRESS

POWER OF MINING CORPORATION TO GIVE MORTGAGE

The statute of California prohibits the directors of any mining corporation from mortgaging any mining ground unless ratified by the holders of two-thirds of the outstanding stock. The ratification contemplated by the statute may be made either in writing or by resolution. The want of authority of the directors of a mining corporation to mortgage mining ground without the consent or ratification of the stockholders, may be raised by anyone who connects himself with the title of the corporation, as well as by any stockholder. This ratification or consent of the stockholders cannot be presumed from the mere fact of the conveyance made by the corporation, as the ratification contemplated by the statute is made after the mortgage is executed. And a mortgagee who accepts a mortgage from a mining corporation and who does not show a ratification by the stockholders, cannot question the validity of another mortgage on the ground that the stockholders did not consent to it.

Bennett *v.* Red Cloud Mining Co., (Cal.) 113 Pacific, 109. Jan. 1911.

INJURY TO MINER—ASSUMPTION OF RISK

A mucker in a mine in a gravel formation discovered a crack in the top of a drift or tunnel running lengthwise of the tunnel. This crack was some five or six feet in length and large enough for the miner to put his fingers in. The attention of the mine-owner was called to the crack, who examined it and said that it looked bad. He then picked at the crack with the miner's pick and afterward said to the mucker: "It is all right. You must shift all loose dirt. You keep working until six. When you quit I will put props under it and hold it up." The miner continued work and in a few minutes a chunk of hard gravel fell from the roof of the tunnel and injured the miner. On appeal from a judgment in favor of the injured miner, it was insisted he had assumed the risk of the danger by continuing the work in a dangerous place. In answer to this the Supreme Court of Washington says that where a question of danger arises and there is a difference of judgment between the master and the servant, and the master assures the servant that it is safe to proceed with the work, the servant proceeds at the risk of the master, and the servant in such case does not assume the risk, unless it appears that there is a new condition following the assurance of the master. The rule of law on this subject is that "where the menace is so uncertain as to cause discussion between the employees and the employer, with the result that the employer dissuades the employee from his apprehension," then the employer is not exempt from liability for injuries to an employee. The miner in this case also had a right to rely upon the promise to repair. The rule on this subject is that where an employer's promise to repair is an inducement to the employee to continue work, he can do so without assuming the risk, unless the danger is sufficient to deter a man of ordinary prudence from continuing the work.

Beseloff *v.* Strandberg, (Washington) 113 Pacific, 250. February, 1911.

LOCATION OF MINING CLAIM—MARKING OF BOUNDARY LINES

The United States statute provides that a mining claim located on the public land shall not exceed 1500 ft. in length alongside the vein or lode, and shall not be more than 300 ft. on each side of the centre of the vein on the surface. Another section provides that locators of mining claims, so long as they comply with the law and local regulations, shall have the exclusive right of possession and enjoyment of all the surface included within the lines of their location, of all veins, lodes, and ledges throughout their entire depth, the top or apex of which lies inside of such surface lines extended downward vertically. Another section requires the locations to be distinctly marked on the ground so that the boundaries can be readily traced. The statute also provides that the owner may obtain a patent from United States by procuring the Surveyor General to survey and plat the same, filing his application in the proper land office and giving the required notice. Under these statutes the grant of the exclusive right to possession on the ground included within the lines of a location is a present grant, and takes effect from the date of the location, and the locator who has established his side lines in good faith is protected against subsequent locators on the land included within the lines as originally located, though it may subsequently develop that by reason of an inaccuracy in the location of the vein or lode, the side lines at the end were more than 300 ft. distant from the centre of the vein. The rule preventing a locator from claiming the excess as against a subsequent locator of adjoining ground, where the side lines are more than 300 ft. from the apex of the vein, does not apply where a claim of the statutory size is originally located in good faith, but through a mistake as to the actual location of the vein as discovered by subsequent exploration, the side lines are in fact more than 300 ft. from the centre.

Harper *v.* Hill, (Cal.) 113 Pacific, 162. Jan. 1911.

Book Reviews

Any of the books noticed in these columns are for sale by, or can be procured from, the MINING AND SCIENTIFIC PRESS.

PRECIOUS STONES. By John Mastin. Pp. 114. Index, pocket size, flexible back. E. & F. N. Spon, London, 1911. Price $1. For sale by the *Mining and Scientific Press.*

This little booklet treats in simple language of the chemistry, properties, and tests of precious stones. The tables of hardness and specific gravity are full and convenient, and to those outside the trade the discussion of imitations and their detection will be of particular interest. The book is un-illustrated and not comparable to the well known work of G. F. Kunz—occupying, indeed, quite a different field. Exception will probably be taken by geologists to Mr. Mastin's conclusions regarding the origin of precious stones. We believe that, while it is true there is room for difference of opinion, investigators generally consider them related to deep-seated igneous and metamorphic agencies rather than to surface waters, even allowing that the latter have penetrated deep into the earth's crust.

THE COPPER HANDBOOK, Vol. X, 1910-1911. By Horace J. Stevens. Houghton, 1911. 1897 pp. + index. Price $5. For sale by the *Mining and Scientific Press.*

The 'Copper Handbook' is so well known as to merit a welcome rather than a review. The tenth volume differs from the ninth chiefly in the additions and alterations made in the descriptions of the copper mines and copper mining companies throughout the world, 8130 in number, which are treated at length in the case of important producers, or dismissed with few lines in the case of dead companies. In this field it is a standard of reference. The first twenty-three chapters, dealing in an admirable way with the history of copper production, the geology, chemistry, and mineralogy of the metal, mining, milling, and smelting, the mechanical technology of copper, and the occurrence and distribution of copper deposits throughout the world, are identical with those of the preceding volume. The technology of the milling and smelting of copper ores has made such rapid progress of recent years that a description prepared two years ago is likely to be *passé,* and it is a tribute to the care with which the volume has been prepared that this is not markedly the case. Much of the general information contained in the volume is not easily available elsewhere, and in the field of detailed information regarding companies engaged in the production of copper, this publication is without a rival. The policy of publishers in sending the volume on approval is an excellent one, and the latest volume deserves and is likely to receive the welcome accorded its predecessors.

Personal

Professional men are invited to send news of their engagements and travels. This news is interesting to friends.

F. J. H. Merrill is in [illegible].

F. [illegible] is in San Francisco.

[illegible] Moore has returned to Los Angeles.

George H. [illegible] has returned to San Francisco.

G. [illegible] was in San Francisco last Saturday.

[illegible] has returned from Austin, Nevada.

F. M. [illegible], of Virginia City, is in San Francisco.

W. G. [illegible], of Los Angeles, is in San Francisco.

H. A. [illegible] has been examining mines in California.

[illegible] has been examining properties in Tuolumne county, California.

[illegible] T. [illegible] has moved his office from Denver to 42 Broadway, New York City.

T. [illegible] recently examined some properties in the Tombstone, Arizona, district.

Sumner S. Smith was at Ketchikan recently, and will spend this month in the vicinity of Juneau.

B. R. Bayne is now manager for the [illegible] Extension Syndicate, Ltd., at Guadalupe y Calvo, Chihuahua.

Victor G. Hills is on his way to Colorado to make an examination there and will return to the [illegible] Mining Co., Nova Scotia, about October 20.

J. Malcolm Maclaren and W. J. Loring were in San Francisco last week and have gone to the Mother Lode region for an extensive tour of inspection.

Gelasio Caetani and Robert MacBoyle went to Humboldt county, Nevada, on Monday. Mr. Caetani will go on to Colorado, and Mr. MacBoyle will remain in Nevada for three or four weeks.

South Dakota's Metal Output, 1910

The mine production of gold, silver, and lead in South Dakota in 1910, according to C. W. Henderson, of the U. S. Geological Survey, was valued at $5,467,[illegible], against $[illegible],319, which included also the value of the copper output in 1909. The gold production decreased from $[illegible] to $5,402,557; the silver production from 144,273 oz., valued at $[illegible], to [illegible] oz., valued at $[illegible]; and the copper output from [illegible] lb., valued at $[illegible], to nothing; but the lead output increased from 1512 lb. in 1909 to 14,[illegible] lb. in 1910. The amount of ore sold or treated decreased from 1,794,141 short tons in 1909 to 1,[illegible] tons in 1910. Of the total State output in 1910, Lawrence county produced all but a small part of the gold and silver, and all of the lead. The famous Homestake mine alone produced over 75% of the precious-metal output. Labor conditions in the Black Hills in the early part of 1910 were the cause of the decreased production, and an increased output may be expected for 1911. The total production of gold in South Dakota since the discovery in 1877 and to the close of 1910 has been $[illegible].

Gold, Silver, and Copper in Wyoming, 1910

The total value of the production of gold, silver, and copper in Wyoming in 1910, according to C. W. Henderson, of the United States Geological Survey, was $[illegible], against $[illegible] in 1909. The gold yield was $[illegible], against $[illegible] in 1909; silver 1478 oz., valued at $[illegible], against 1767 oz., valued at $[illegible]; and copper 222,[illegible] lb., valued at $[illegible], against [illegible] lb., valued at $[illegible]. The amount of ore sold or treated was [illegible] tons, against [illegible] tons in 1909. There were 12 producing mines in Wyoming in 1910, of which 4 were gold placer mines. Copper has been the most important metal produced in Wyoming, and the State is to be credited with a total output of [illegible] lb. of copper from 1881 to 1910, inclusive.

Company Reports

ALASKA TREADWELL GOLD MINING COMPANY

The twenty-first annual report, for the year ended May 31, of the Alaska Treadwell G. M. Co., which has mines and works on Douglas island, Alaska, shows a net profit for the year of $710,312. Operating costs amounted to $1,177,253, of which $857,813 was paid for mine development, $157,263 in milling expenses, and $88,777 for treatment of sulphides by the Tacoma Smelting Co. and in the cyanide plant. Construction and repair costs amounted to $18,696. After deducting the Alaska United G. M. Co. gross returns from the 700 Ft. Claim, ore crushed in Treadwell mills, the company received by bullion account $1,811,285. It received in interest $8405, and in commercial profits from supplies, foundry, butcher-shop, boarding-house, and coal, $86,572, making total receipts for the year of $1,906,262. No sulphides are on hand. A surplus of $86,294 was carried over. No work was done in the open pits, but in the eight levels of the mine a total of 9150 ft. of development and exploration work was done, divided as follows: drifts, 1287; cross-cuts, 2249; raises, 3261; intermediate drifts, 1167; and stations, 1186 ft. The year before the company did 13,011 ft. of development work. In addition to this work, the company, during the year just closed, did 590 ft. of development work in the Alaska United G. M. Co.'s 700 Ft. Claim mine, against 979 ft. the previous year. A total of 770,084 tons of ore was sent to the mills, the figures including 600 tons of ore from the 700 Ft. Claim mine. The ore broken in both mines amounted to 996,368 tons, and the waste to 25,722, making a net increase in ore broken of 226,284 tons. The ore reserves, above the 1600-ft. level on May 15 were as follows: ore in place, 5,408,960; broken ore in stopes, 1,228,410; making a total of 6,637,370 tons. The ore above the 1750-ft. level is not sufficiently developed to estimate. The estimated ore reserve for the previous year was 744,226 tons. The ore sent to the mill the previous year amounted to 744,226 tons and had an average assay value of $2.95 per ton, including the value of the tailing. The ore for the year just closed had an average assay value of $2.53 per ton. The total number of feet drilled in the mine for the year was 920,545, and the number of tons broken, 1,021,765, making an average of one ton broken per 0.9 ft. drilled. The average costs were: for labor drilling, $6.86; explosives, $2.62; supplies, power, and repair, $4.02. The figures are for both the Treadwell and the 700 Ft. Claim mine of the Alaska United. An average, in both mines, of 43.87 machines per shift of 10 hours was used during the year. The average drilling of one machine per shift was 29.4 ft., and the average amount of ore broken per machine per shift was 32.74 tons. The average assay value of 3444 samples taken in the Treadwell mine during the year was $3.04. The mill-record of the 240-stamp mill shows that it was operated about 182 days on steam-power, 168 on water-power, and was idle 15 days. The ore crushed amounted to 395,332 tons, an average of 4.71 tons per stamp per 24 hours, from which 7339 tons of sulphides was saved. The quicksilver used amounted to 75,345 oz. The free-gold output in value was $566,639, and concentrate output was $371,377. The total value of tailing was $86,391. The gross output was $1,024,407. The quicksilver lost in the retort and mill was 27,188 oz., or 36.08%. The 300-stamp mill worked about 210 days on water-power, and 17 days on electricity, and lost 138 days, crushing 374,752 tons of ore, an average of 5.5 tons per stamp per 24 hours, from which 6607 tons of sulphides was saved. The quicksilver used amounted to 83,234 oz. The free-gold output was $510,255, and the concentrate output was $352,859 in value. The value of the tailing was $61,858, making a total gross output of $924,971. The quicksilver lost in retort and mill was 30,956 oz., or 37.19%. All dies for this mill were cast in the Treadwell foundry, but some of those used in the 240-stamp mill were chrome-steel, and some were from the Treadwell foundry. The stock of chrome-steel dies, which had been in stock for several years, is now exhausted. The Westinghouse-Parsons steam-turbine plant, and the hydro-electric plant on Sheep creek have been completed and are in use. A water-power site on Nugget creek, about 14 miles from Treadwell, has been purchased. The company's share in the above power properties is $147,841. After three years experimenting, a cyanide plant with a capacity of 100 tons per day has been built. With it the treatment of concentrate is cheaper than by shipping to the Tacoma smelter. The company's total expense to date for this is $123,333, of which $78,369 was spent last year. Owing to the press of the company's work, a large amount of outside business has been turned away from the machine shop. In the office-building a reinforced concrete, 2-story vault was constructed at a cost of $1398. A wharf for receiving explosives and other merchandise cost $6783. A 10,000-bbl. salt-water tank and pipe-line, for supply during the winter water shortage, cost $7236. Profit on merchandise sales amounted to $51,788. For the Treadwell club-house a tank and baths were built. During the year there were 19 accidents, of which 11 were fatal, giving a fatal-accident rate of 5.69 per 1000 for the 1935 employees exposed to risk. There has been a satisfactory labor supply for all departments. Wages range from $3 per day for mine laborers and blacksmiths' helpers to $120 per month for amalgamators; the average wage for the 740 men per day employed being $3.39 per day. The property and plant of the company, after writing off $100,000 for depreciation, are valued at $4,706,818.

WAIHI GOLD MINING COMPANY, LTD.

This company, which is capitalized at 500,000 shares of £1 each, owns 915 acres at Waihi in the Thames district, New Zealand. Three stamp-mills are in operation, the Victoria of 200 stamps, the Waihi of 90 stamps, and the Union of 40 stamps, a total of 330 stamps and 15 tube-mills. The report for the year ended December 31, 1910, shows that during the year 442,020 tons of ore was treated, yielding £926,100. The operating costs were as follows:

Mining	£142,776
Development work	20,071
Tramming ore to mills	5,609
Milling	55,146
Cyaniding ore and concentrate	78,947
Repairs to plants	10,510
Export duty on gold and rent to Government	19,162
Other expenses	47,556
Total	£379,777
Operating profit	£559,192

For depreciation on plant and machinery, £36,761, corresponding to 10%, was written off; £30,730 was expended on the construction of a hydro-electric plant; £18,474 was expended on capital account; £44,281 was paid as income tax; £10,000 was transferred to the reserve fund; four dividends of 4s. each, amounting to £396,725, were paid; a bonus of 2s. per share was paid on June 1, or a total of 18s. per £1 share, and £57,700 was carried forward. In its balance-sheet the company has an investment account of £242,195, chiefly in Government bonds. Since the formation of the company, 71 dividends have been paid, a total of £4,251,554. As the progress of development in the deep levels indicates that some of the veins are becoming impoverished in depth, and as the development work was not adding to the reserve an amount of ore equal to that being extracted, upon the recommendation of R. E. Williams, who was engaged to make a special report upon this question, the rate of milling will be reduced to 1000 tons per day until development work shows the necessary increase in ore reserve, which now amounts to 1,063,000 tons, not including a possible 600,000 tons in pillars. A hydro-electric power-plant is in course of construction at Hora Hora on the Waikato river, to utilize a fall of 24 ft. The power station will contain 6 turbines of 1500 hp. each, and the current, at 50,000 volts, will be transmitted 49 miles to the mine at Waihi.

McCaskey, Advance Chapter from 'Mineral Resources,' pp. 20; The Production of Abrasive Materials in 1910, by W. C. Phalen, pp. 17.

Steel Corporation Pacific Coast Department

The United States Steel Products Co., which handles the export trade of the United States Steel Corporation subsidiaries, has organized a Pacific Coast department, which will have charge of selling and distributing its products on the Pacific Coast. The enlargement of the corporation's operations in that territory and the carrying of much larger stocks of finished material than heretofore were indicated some time ago by the acquisition of the Risdon Iron Works, with their extensive water frontage. It was then stated that the building of large warehouses was contemplated, particularly stocks of sheets and tin plates, pipe and tubes, wire products, structural steel and bars. The new department will not only sell from warehouse stock but for direct shipment from mill the product manufactured by the American Bridge Co., the American Sheet & Tin Plate Co., the American Steel & Wire Co., the Carnegie Steel Co., the Illinois Steel Co., the Lorain Steel Co., the National Tube Co., the Shelby Tube Co., and the Tennessee Coal, Iron & Railroad Company.

The warehouse business of the corporation on the Pacific Coast will also be consolidated under the jurisdiction of the new department, which will take over, carry, and handle the stocks of the subsidiary companies at the established distributing points in that territory. These offices and warehouses are at San Francisco and Los Angeles, California, Portland, Oregon, and Seattle, Washington. The executive officers of the United States Steel Products Co. in charge of the new department are: A. T. De Forest, vice-president; W. A. Ross, assistant treasurer; H. F. Wilson, auditor and assistant secretary. The headquarters will be in the Rialto building, San Francisco.

Commercial Paragraphs

The PACIFIC FOUNDRY CO., San Francisco, has recently shipped two Kilker matte tapping cars to the Mason Valley Mining Co. in Nevada, and three to Chile.

The LALLIE SURVEYING INSTRUMENT & SUPPLY CO., of Denver, has moved to larger offices at 1710 Champa St., and is in better shape to handle its increasing business.

T. D. SMITH, formerly with the Commercial Electrical Co. of St. Louis, Mo., is now with the electrical department of the Mexico Mine & Smelter Supply Co., at Mexico City.

HENRY R. WORTHINGTON, 115 Broadway, New York, announces the opening of a district office and warehouse at Eighteenth and Blake streets, Denver, Colorado. C. L. Newcomb, Jr., is in charge.

The LUNKENHEIMER CO., of Cincinnati, Ohio, entertained the delegates and visitors to the National Association of Stationary Engineers which recently met in that city, with a river ride and outing. Nearly 3000 guests enjoyed the company's hospitality.

'The Labor Saver' is published monthly by STEPHENS-ADAMSON MFG. CO., Aurora, Ill. The September issue contains, among other things, an interesting article on a 'Conveyor System for a Modern Stamp-Mill,' and describes the equipment furnished by Stephens-Adamson Mfg. Co. for the Goldfield Consolidated mill.

The GOULDS MANUFACTURING CO., Seneca Falls, N. Y., has just placed a new high-pressure Triplex power pump on the market. This pump, known as Fig. 1585, is similar to the Fig. 1283 type, which is in general use in mines, water-works, and with hydraulic elevators, fire-protection systems, hydraulic presses, oil pipe-lines, etc. The chief difference is in the gearing. The new pump has only one gear and pinion, which are located between the standards. Fig. 1283 has two sets, one on either side of the standards. Placing the gearing between the standards necessarily lengthens one side of the pump somewhat, and increases the distance between the two valve-boxes on that side. Instead of lengthening the pipe connection between the valve-boxes on one set and making each set of a different shape as they are in many pumps, a distance piece is put in. In this way the three sets of valve-boxes are kept identical in form and interchangeable. This duplication of parts is a feature of Goulds pumps which is greatly appreciated by the purchaser, and one that saves valuable time when repairs are needed. It also reduces the number of parts kept in stock by the large user who may be located at a great distance from the factory.

Catalogues Received

COCHISE MACHINE CO., Los Angeles. Bulletin C. S. 1, 'Cochise Stoping Machines.' 8 pages. Illustrated. 7 by 10 inches.

THE MORAN CO., Seattle, Wash. 'The Little Giant Stamp Mill and the Christensen Concentrator and Slimer.' 40 pages. Illustrated. 6 by 3½ inches.

THE GOULDS MFG. CO., Seneca Falls, New York. Bulletin No. 102. 'Single-Acting Triplex Plunger Pumps.' 12 pages. Illustrated. 8 by 10 inches.

TRENT ENGINEERING & MACHINERY CO., Salt Lake City, Utah. Catalog No. 6, 'The Monadnock and Other Chilean Mills.' 36 pages. Illustrated. 8½ by 11 inches.

ALLIS-CHALMERS CO., Milwaukee, Wis. Bulletin No. 1068 (Reprint). 'Direct Connected Corliss Engines.' 8 pages.

Bulletin No. 1074. 'Direct Current Motors and Generators.' Types 'H' and 'H-I.' 12 pages.

Bulletin No. 1083. 'Direct Current Motors and Generators.' Type 'K.' 20 pages. All illustrated. 8 by 10½ inches.

BUSINESS transactions are often an index of political conditions, and the confidence in the government established in Mexico under the newly elected president, Francisco I. Madero, Jr., is exhibited by a recent transfer of some 50,000 acres of land in Sonora to American interests.

MASSACHUSETTS Institute of Technology will remove to Cambridge. Like Columbia University when at Forty-ninth street, New York, it has found its situation in the heart of the city too circumscribed and must seek larger space for growth. And at Cambridge it will have the best of neighbors.

MANY members of the American Institute of Mining Engineers sailed for Japan on Tuesday, the party numbering about eighty. While in Japan they will be the guests of the Japanese Mine Owners Association, and, having experienced Japanese hospitality, we can predict for them a most delightful experience. H. Foster Bain is a member of the party, and will return to San Francisco with them early in December.

ONE of the effects of smelter fume is seen in the closing of the post-office at Coram, Shasta county, California. This was an important town when the nearby smelter was in operation, but since the local agriculturalists secured the shutting down of the smelter hardly anything is left of the once prosperous community, and even the farmers can scarcely claim that the increase in agriculture counterbalances the loss to the commonwealth by the abolition of a town and the cessation of the production of a useful metal.

BANKING and currency reform are issues of such vital importance as to warrant even more widespread interest and discussion than they now receive. Mr. James J. Hill has recently traversed the views of Mr. Nelson Aldrich in an address before the Illinois Bankers' Association, asserting that centralization can be better attained through the initiative of the bankers, rather than by Federal enactment. The readjustment of a system that extends throughout the body politic offers so much difficulty that many will re-echo the utterance of Mr. J. P. Morgan: "How can you unscramble scrambled eggs?"

TONOPAH geology has been the subject of much discussion and even more study, the final views on the structure of that district put forth by Mr. J. E. Spurr being the result of protracted investigation underground. At the San Francisco meeting of the American Institute of Mining Engineers Mr. Augustus Locke presented a paper, of which we give an abstract this week, reviewing the conclusions of Spurr and Burgess. Having the benefit of the large amount of previous work by other investigators, Mr. Locke's conclusions are of much interest, but in fairness to himself it would perhaps have been wiser to have presented more evidence rather than conclusions. The question of persistence of the orebodies in depth is so largely bound up with a correct interpretation of the geologic structure of this interesting area, that we need offer no apology for reopening its discussion.

REBELLION is rife in China and it appears not unlikely that the Manchu dynasty will be overthrown, the seriousness of the situation being evidenced by the masterly way in which international complications are being avoided by the revolutionary leaders as well as by the success which has so far attended their arms. Meanwhile the daily journals, which struggled manfully with the difficulties imposed upon them by the Turkish-Italian war, have met their Waterloo in the Orient. Even the well informed and accurate *Chicago Tribune*, publishes a supposed photograph of the Emperor Hsuen Tung, showing a boy of three times his age, and another of some unrecognizable person as Prince Ching, whom it designates as the Prince Regent. Other journals take seriously the schoolboy talk of a republic put forth by the Young China Association, and the bombast of that erstwhile reformer, Sun Yat-sen, but cablegrams direct from Peking are usually reliable, being sent by reliable correspondents.

AMONG the many interesting and valuable exchanges which come to our desk, *The National Review* of Shanghai is one of the most appreciated. Published in a country where the journals are notoriously ill informed, and partisanship and bias, both national and individual, are rampant, it shows itself in possession of the essential facts and discusses them with commendable fairness. It also furnishes us a convenient way of keeping track of the mails between San Francisco and Shanghai by observing the time which elapses after the publication of an issue of the *Mining and Scientific Press* before material taken from it appears without credit in *The National Review*. 'Lifting' of material from our columns is so common an experience that it does not greatly disturb us, and affords, indeed, a convenient way of securing the opinions of our contemporaries as to what is most valuable and interesting in our columns. But in its issue of September 9 *The National Review* 'lifts' one of our editorials of the early summer, and by a slight change in the opening sentence and the addition of another at the end, converts it into an argument for its own purposes. Ethics, both social and journalistic, are lax in the Orient. In this respect, Mexico also appears to be an Oriental country, and *The Mexican Herald* has the habit of reprinting signed articles taken from the columns of the *Mining and Scientific Press* in such a way as to lead its readers to believe them original contributions to its own columns.

CYANIDATION offers problems as many faced as a diamond, and one of the sides that recently have been to the fore presents the questions involved in the cyanidation of concentrate. In his well written and interesting paper, which we print in abstract this week, Mr. W. P. Lass describes the careful experimental investigations carried on at the Alaska Treadwell and the final successful carrying out of the operation, and the many ingenious modifications introduced to meet the special conditions there existing will be of much interest to our readers. It is interesting to note further that in the beginning of the cyanide process the development of the chemical theory was far in advance of its mechanical development. But in recent years the many and varied mechanical problems have been attacked with so much energy and ingenuity that there is now more likelihood of the mechanical equipment being in advance of the chemical development of the process. The chemical side has recently been touched upon by Mr. J. E. Rothwell, who calls attention to the fact that the process is essentially a chemical one, and that mechanical equipment, though enormously important, is in reality subordinate to the chemical reactions involved. It is safe to predict that the most notable steps in the advance of the application of the cyanide process during the next few years are likely to be chemical rather than mechanical. We are accustomed to look to the technical schools and universities for the theoretical development of technical subjects, but in this respect the results have of late been singularly disappointing. One of the exceptions is a notable paper of slime filtration by Mr. G. J. Young, which we will present in abstract next week.

Pragmatism

The necessary adjustment of means to ends is clearly recognized in philosophy, but in its pragmatic application does not always receive the careful attention it deserves. In a broad way the principle is recognized, of course; no one employs a locomotive to propel a baby-carriage, nor attempts to move freight trains by muscular power. But where the incongruity is less obvious, and especially in the manifold applications of physical and mathematical formulae and constants to the affairs of everyday experience, intelligent insight and nice discrimination are more infrequent. Even engineers can at times be detected in dividing a number, known to be accurate only to the first decimal place, by another equally inaccurate, and carrying the quotient out to several places of decimals. Estimates of ore reserves carried out to the first or second decimal place of tonnage and to the last cent of value, appear so frequently in reports that the critical reader is driven to wonder whether it is possible to pass the mathematics courses of our universities without acquiring the fundamental concepts of mathematics. In the case, for example, of determining the extent and value of a nearly horizontal orebody of fairly uniform character by churn-drilling it is easily apparent that under ordinary circumstances it will not be practicable to measure the depth of ore found in the hole more closely than to the nearest tenth of a foot. This error, distributed over a block of ground, corresponds to a necessary plus or minus error in estimates of several tons. The two distinct steps in estimating the tonnage should be clearly distinguished; the measurement of the depth of the ore is an experimental observation subject to a large number of experimental errors, both constant and accidental; the subsequent computation is a mathematical operation which may be carried out with any desired degree of precision; with a slide-rule or by the use of six-place logarithms, for example. But it must be remembered that the use of the six-place logarithms cannot educe from the approximate data a precise result any more than the minting of lead into dollars will transmute the base metal into silver, and the application of a method of which the precision is greatly in excess of the precision of the data employed is as obviously a waste of time and effort as the action of the assayer who was accustomed to estimate the amount of flux required in his assays and then weigh out the estimated amount to the nearest tenth of a gram. The further steps in obtaining an estimate of the value of an orebody will likewise repay analysis. The chemical determination of the content of each sample is performed with great exactness and the average result of a large number of samples will have a high degree of precision. If, for example, from the analysis of several hundred samples it is determined that the orebody, estimated to contain 100,000 tons of ore, has an average content corresponding to metal worth $9.75 per ton, the estimate is a precise one, so far as the chemical work is concerned and an investigation of the limits of error would possibly show that this result was subject to a ± error of $0.03. On the other hand, the samples taken may fail to represent the average of the orebody by as much as $0.80. Similarly, when we say that the ore has the mineral content mentioned, corresponding to an operating profit of $1.50 per ton, we have taken a change of venue that entirely shifts the limits of accuracy. That the profit will be $1.50 per ton may be either the merest guess or a reasonably accurate deduction, according to the method by which that result was obtained. To use a metaphor, we may laboriously scale the cliff of investigation holding fast by one assured fact after another, but if we trust ourselves to the loose and crumbling rock of insecure data, or if we let go of fact at any point disaster will follow. And precise computations cannot educe accurate results from approximate data any more than a stable structure can be built of granite blocks upon a foundation of sand. One practical feature must not be overlooked here, one which we may perhaps call the bookkeeping of mathematics. When it is necessary to add together a number of results, some of which are precise while others are only approximate, the resulting total will exhibit an appearance of accuracy which is not in keeping with its true character. The true sum should contain no more significant figures than the least precise of its components, and we are obliged to choose between a total which is not the mathematical sum of its components and a total which exhibits a false appearance of accuracy. This is frequently a problem in the keeping of accounts, books must balance, and the convenience of having them balance is so great that it may well be judged desirable to secure it at the expense of a due regard for the errors inherent in the results dealt with. Careful consideration of the factors involved will disclose the proper adjustment of means employed to results desired.

Panama and the Nations

Such an occasion as a presidential visit celebrating the commencement of material preparation for the great Panama-Pacific Exposition has deep significance. It constitutes an opportune moment for announcements of Governmental policy. It is natural to scrutinize the words of President Taft at these exercises to ascertain something more than they seem openly to tell. There necessarily must be veiled meanings in any diplomatic utterance; the world is too closely knit in these days to admit of one nation venturing to establish policies that disregard the interests of others, save when there is peculiar stress, and when the risk of war has not to be regarded.

For three hundred years the world has realized that a canal must be cut across the Isthmus; for three hundred years there have been maneuverings among the nations to obtain advantage in determining the future political status of the isthmian countries; to gain a foothold on Central America if possible; to prevent a selfish domination by any single power. Twice America trembled on the verge of war with England over the difficulties growing out of rivalry for control of the Isthmus. Once, to the great pain of Lord Palmerston, an American naval officer undertook to emphasize his opinion of political propriety by opening fire upon the city of Greytown, despite the fact that the British flag was waving over its ramparts. Happily such incidents as these can not now be repeated. The Mosquito Coast has lost its strategic importance, and only a few years ago we saw the tripartite treaty which guaranteed the British protectorate under Nicaraguan sovereignty ruthlessly torn to shreds without even calling for the landing of British marines.

It had become plain that it was the destiny of America to build the American canal. It has become evident that only America could be trusted to effectively hold and guarantee the neutrality of such a waterway. America is great, America is big, but America is not aggressive in international politics. The American people have a habit of attending to their own domestic affairs, and in the spirit of good husbandry they are equally determined that no one shall disturb their domestic tranquillity. It was less the fear that the United States would unduly benefit by special privileges in a trans-isthmian canal than that other nations might by hook or crook secure discriminative advantages, that a cobweb of treaties was woven around any future canal guaranteeing its use to all nations under equal terms. Thus were we bound to use our birthright with careful regard to the interests of other nations, but there exists no such treaty as that which specifies the regulations governing the Suez Canal to embarrass us at Panama. We have been allowed large liberty, though we have not been permitted a free hand. This the American people seem not to fully understand, just as they forget why a certain clause in the tariff laws has remained inoperative for generations, so that no merchant has yet applied for the rebate of ten per cent which these laws accord him on goods imported in American bottoms; they forget the little 'joker' which recites that nothing in the law shall conflict with existing treaties, conventions, or agreements with foreign powers. In passing we may mention that some very interesting history lies back of that little 'joker'; also some very interesting history precedes the weaker shackles which have been put upon us in regard to the Panama Canal.

With keen interest, therefore, we have listened to the utterances of President Taft at the opening of active work upon the Panama Canal. With perfect logic, like a mathematical necessity, he touched upon the three vital points: the Monroe Doctrine, preferential Americanization of the Canal, and arbitration. In somewhat undiplomatic manner he tells us that he will make the Central Americans stop cutting each others' throats, which we suppose will mean the doing of what our European friends have so long asked us, if we intend to be consistent, namely, to assume the responsibility of policing Latin America. Heaven defend us from annexation! We do not wish to see the corruption that would occur to some generations of men through an attempt to do again what we did in California and the Southwest.

The significance of a firm re-assertion of a Monroe Doctrine properly applied, lies in giving us the excuse to insist upon preferences in the use of the Canal. Existing treaties recite that the Canal must be neutral; the President was silent upon this point; in fact it was needless to mention it, for if Europe objects to fortifications it is perfectly easy to maintain adequate fighting fleets convenient to either entrance. The late Secretary Blaine remarked that "any trans-isthmian canal would be essentially an extension of our coast-line." The American people believe this; President Taft believes it; he tells us that in some way American ships must have the free use of the Canal. There is some humor in it, because there is only one way in which it can be done, unless we wish to be unnecessarily disagreeable to our friends across the water, and that is doing as a government what the Government has denied the railroads the right to do—to grant a rebate in the form of a subsidy to American ships which may use the Canal, sufficient to offset the tolls collected. There are times when a rebate is necessary, which shows us how unmoral ethics is. There seems no reason why this method should not succeed. Any other nation may grant an equal subsidy to its ships passing through the Panama Canal, and thereby enjoy its use under equal terms with us. All these matters are parts of a delicate international mechanism, and a false move of the hand of the engineer might precipitate disaster. Some one's clothing might be caught by a set screw on the shaft and wind him around it, to the consternation of the world. In short, Mr. Taft is pleasantly disposed toward general arbitration treaties, because . . . it is so transparent, we need say no more!

The Cyanide Plant at the Treadwell Mines, Alaska

By W. P. Lass

*The purpose of this article is not only to describe the plant and method of cyaniding the Treadwell concentrate, but to present some of the results of experimental work during the past three years for the Alaska Treadwell Gold Mining Co., at Douglas island, Alaska, under the direction of F. W. Bradley, consulting engineer, and Robert A. Kinzie, general superintendent, of the affiliated companies.

At the time the experimental work was undertaken the concentrate was being shipped to the smelter at Tacoma, and the cost for treatment of 3-oz. (gold) concentrate was $11.95 per ton.

From the experimental work it was estimated that 96% extraction could be made by treatment at the plant, and that the cost, when treating 80 tons per day, would be $3.25 per ton. Adding to this the 4% treatment loss, which on 3-oz. concentrate amounts to $2.48, gives a total cost of $5.73 per ton, a net gain of $6.22 per ton by the local treatment. In addition to this saving, the cyanide tailing would have an economic value due to the sulphur and iron content, as well as the value of the residual gold after oxidation.

The concentrate, amounting to 1.8% of the original ore, contains: Fe, 40%; S, 1%; SiO_2, 11%, and carries from 2.5 to 4 oz. gold and 0.75 oz. silver per ton. The gold and silver amount to about 37% of the original content. The figures in the following table are assays and averages of sizing tests on concentrate from the various mills.

Assay Sizing Tests of Treadwell Gold and Silver Ores

Size of material.	Wt. %	Assay value per ton.	Value %	Value in 1 ton of original.
On 20-mesh screen...	0.44	$70.35	0.48	$0.31
Through 20, on 40.	8.23	203.96	26.05	16.83
Through 40, on 60.	10.96	143.89	24.39	15.76
Through 60, on 80.	12.49	94.88	18.34	11.85
Through 80, on 100.	10.38	60.85	9.78	6.32
Through 100, on 120.	13.37	39.27	8.14	5.25
Through 120, on 150.	7.69	26.61	3.17	2.05
Through 150	36.46	17.10	9.65	6.23
	100.00		100.00	$64.60

Preliminary tests were made in glass jars, after which 50-lb. composite samples were ground to 200 mesh in a clean-up barrel provided with iron balls, the pulp passed over amalgamated plates and then agitated in small Pachuca tanks, 4 ft. high and 14. in diameter. The results showed that 75% of the gold could be recovered by fine grinding and amalgamation and 96% by amalgamating followed by cyaniding. The next step was the construction of an addition to one of the mills and the erection of a 4 by 12-ft. Abbé tube-mill. Various forms of classifier were tried, the Dorr proving most satisfactory. Callow cones were used for dewatering, and the agitation was carried on in a Pachuca tank 10 ft. diam. and 22. ft. high. The complete results of the first 25 experimental runs are seen in the table given below. Throughout this paper the ton of 2000 lb. is used, with gold at $20.67 per oz.; no account is taken of the value of the silver.

* All values are in gold at $20 per ounce. Tests 2, 6, 8, 9, 10, 16 and 17 given preliminary alkali agitation.
All solutions contained an excess of lime.

RESULTS OF FIRST 25 EXPERIMENTS ON CYANIDING CONCENTRATE.

The results of the tests showed that 75% of the gold could be recovered by grinding and amalgamating, or 96% by the combined method of amalgamating and cyaniding. Results also showed that during the process of grinding in 1.5-lb. (0.075%) cyanide solution, a similar extraction could be obtained without amalgamation. Thus a satisfactory extraction was obtained either by amalgamating and cyaniding or by cyaniding direct. A preliminary agitation with an alkali solution was found to shorten the time of cyanide treatment and save 25% in the cyanide consumption. Passing the air used for agitation through a receiver filled with a solution of caustic soda or milk of lime also decreased the cyanide consumption, presumably by the removal of oil and CO_2 from the air. When grinding in solution over 1 lb. per ton (0.05%), followed by amalgamation, it was difficult to keep the plates bright, due to a dull white surface deposit, which if allowed to remain turned to a dull gray. A muntz-metal plate was substituted for a copper plate, but as all the plates were coated no variation in the result was noted, and there did not appear to be any essential advantage gained from its use.

The results obtained from this extended period of investigation, lasting over two years and costing $27,794, justified the building of a plant of 100 tons daily capacity. The preliminary cost was largely offset by the ability of the final plant to treat the concentrate without the usual altera-

---

*Abstract of a paper presented at the San Francisco meeting of the American Institute of Mining Engineers.

tions necessary in starting a new mill. It also produced the nucleus of the final mill crew. As the abandonment of amalgamation in favor of direct cyaniding seemed a somewhat radical change, the new mill was planned to operate either way, and ultimately nearly 5000 tons was treated by each method before deciding to cast out the time-honored amalgamated plate. All of the equipment purchased for the experimental work was used in the permanent plant, which was completed in September 1910.

The cyanide plant consists of three buildings situated on a hillside 200 ft. above the stamp-mill. The upper building contains the grinding and amalgamating plant, with a lower floor for solution storage tanks. The lower contains the cyanide equipment proper, while the refinery is in a concrete building at one side, as shown in the illustration. The five mills on Douglas island contain a total of 900 stamps, and crush approximately 5000 tons per day. The crushed ore after amalgamation is concentrated on 360 Frue vanners, yielding an average of 90 tons of concentrate per day, of from 2.5 to 4 oz. gold per ton. The flow-sheet of the operations is given on the next page.

From the vanner-boxes the concentrate is shoveled into specially constructed flat-bottomed steel cars. These cars, each holding two tons of concentrate, are made up into trains at the mills, and brought by locomotives to the foot of the incline below the cyanide plant. This incline is 900 ft. long with 14° rise. A Union Iron Works geared hoist, driven by a 75-hp. electric motor, brings the train to a switch above the upper building. Beginning with this switch, the entire plant is in duplicate throughout. Leaving the switch by gravity, the cars are weighed, sampled, and run into revolving tipples. Upon releasing the brake the tipple revolves, turning the car bottom up and dropping the load from the car. The change in the centre of gravity then causes the tipple to right itself, and the empty car is weighed and returned to the main switch.

Most of the water is removed from the concentrate while in the vanner-boxes by the aid of a bumper, which is simply a large air-piston machine mounted on a truck and moved from box to box. This bumping causes the particles to readjust themselves and pack in the bottom of the box, while the water runs off, leaving about 12% of moisture in the concentrate. It is considerably easier to shovel the concentrate into the cars after the bumping. The concentrate is sampled while in the car by means of a long ship-auger. With the ordinary long spoon it was impossible to obtain satisfactory checks in the samples, as the concentrate is usually covered with water. Unslaked lime is added to each of the empty cars as it leaves the tipple in order to reach the concentrate at the earliest possible stage. It also forms a line of cleavage, causing the concentrate to dump clean from the bottom.

From the cars the concentrate falls into 100-ton steel storage-bins, 15 ft. diam., with 55° conical bottoms. The concentrate in the bins is kept covered with water, which effectually prevents oxidation of the sulphides while lying in the bins. From this point until the cyanide treatment begins the concentrate is in strong lime solution at all times. At the apex of the conical bottom of each bin tight fitting gates control the outflow, which is at once sluiced directly into Dorr classifiers. The sluicing medium is the coarse return product referred to later. There are three Dorr classifiers driven by one 7.5 hp. electric motor, one feeding into each tube-mill and making 21 strokes per minute. This rate of speed, causing greater agitation, was found necessary to separate the large bulk of the fine from the coarse.

The coarse product of the classifiers falls into the spiral feeders of the tube-mills. These mills are of the Abbé type, 5 by 22 ft., lap-welded, trunnion bearings, with corrugated sectional liners; 3-in. Danish flint pebbles are used for the grinding. Two 75-hp. motors on three-phase circuit at 2200 volts are belted to an overhead central line-shaft, which in turn is belted to the pinion shaft of the tube-mills. The tubes are driven from the discharge ends and make 27 rev. per min. The mills are controlled by friction-clutch pulleys on the central line-shaft. For the period from May 15 to July 15, 1911, one tube-mill ground at the rate of 88.75 tons of concentrate per 24 hours actual running time, the power consumption averaging 64 hp. By replacing each 75-hp. motor with a 100-hp. motor, and substituting leather for canvas belts on the main drive, the power consumption was reduced to an average of 59 hp. for the same tube duty. This was with the tube just half filled with pebbles, the normal running load. By increasing the pebble load to 6 in. above the centre of the tube, the power consumption rises to 75 hp., and both the quantity of tube feed and the fineness of the product discharged are increased.

CYANIDE PLANT OF ALASKA TREADWELL G. M. CO.

The following is an average screen analysis of the feed and discharge of one 5 by 22-ft. mill, when grinding an original feed of 88.75 tons per 24 hours:

	On 100 mesh.	On 200 mesh.	Through 200 mesh.
	%	%	%
Feed	48.7	41.5	9.8
Discharge	10.1	26.4	63.5

The pulp contained 38.5% moisture.

When the concentrate is amalgamated previous to cyaniding, the product discharged from the tubes is distributed over 10 copper amalgamating plates, each 4 ft. 8 in. wide by 10 ft. long, plated with 2 oz. of silver per square foot. The pulp flows from the plates into launders built into the floor. No traps are used, as they are quickly clogged by the metallic iron which accumulates in the concentrate from the wear of the various machines used in the processes of mining and milling. This iron, if allowed to accumulate in the coarse return-product, will amount to as much as 15% of the total. Experiments are now being carried on with a magnetic device for removing the iron from the pulp. From a sump in the launder an air-lift elevates the pulp to a spitzlutte, from which the coarse material is continuously drawn into a Dorr classifier, the coarse from which feeds a 4 by 12-ft. Abbé tube-mill, similar to the larger ones described above. The discharge from this mill joins the overflow from the spitzlutte, and is elevated by air-lifts to two settling-cones, so situated that the spigot-discharge from them becomes the sluicing medium for the original feed referred to above.

Two points will be observed here: (1) that the Dorr classifiers are at present doing all the classifying for the mill; and (2) that the concentrate is carried around in a closed circuit from which there is no escape until the particles have become fine enough to join the overflow from the back of the Dorr classifiers. The Dorr overflow, which is the product cyanided, is more than 98% through 200-mesh. The remaining 2% is silica from the wear of the pebbles. Of the concentrate, the entire product will pass a 200-mesh screen. The overflow from the Dorr classifiers passes into two Callow dewatering cones, the spigot product of which is distributed over 10 amalgamating plates similar to the coarse amalgamating plates previously described. From the plates the pulp flows into launders, thence into a 6-in. pipe, 37 ft. long, having a fall of $^3/_4$ in. per foot, which conveys the pulp directly to the lower or cyanide building. In the lower building the pulp is received into a wooden distributing-box, from which it flows through two Pierce amalgamators into four 8-ft. Callow cones. The spigot-product from these cones discharges into four similar ones placed lower than the first set.

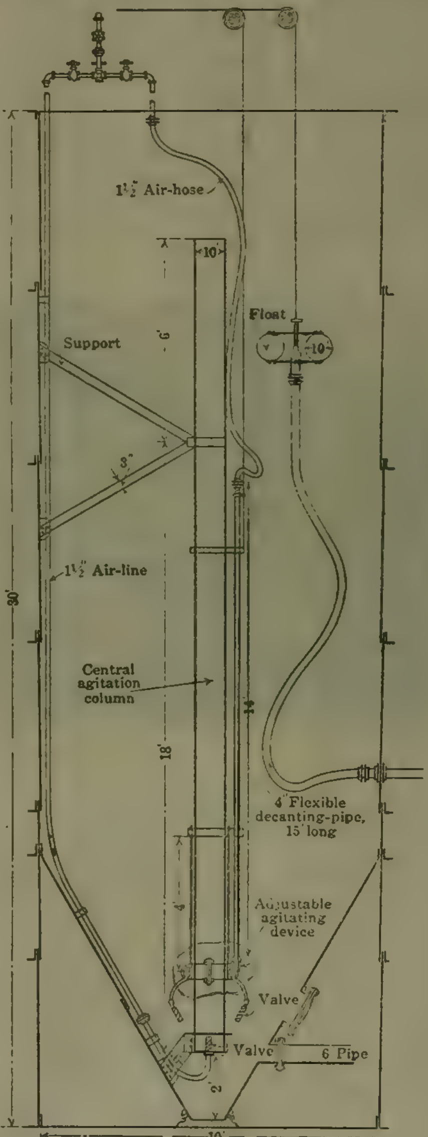
FLOW-SHEET, 100-TON MILL.

The spigot-product from the lower cones enters one of four Pachuca tanks, where it receives a preliminary treatment of 3 hr. agitation in a solution containing 2 lb. of lime per ton (0.1%), after which it is allowed to settle and the clear solution is decanted. The filling, agitating, settling, decanting, and discharging of a 25-ton charge of concentrate, which includes 46 tons of lime solution, requires somewhat less than 24 hr. This preliminary treatment saves in the subsequent treatment at least 1 lb. of cyanide per ton of concentrate. The overflow lime-water from the Callow cones enters the same sump with the decanted lime-water from the preliminiary treatment, and is pumped by an Aldrich triplex 7 by 9-in. electric pump into a reservoir of 75 tons capacity situated in the upper building. The thickened pulp, ranging from 1.8 to 2.2 specific gravity, is drawn into one of eight Pachuca tanks, where it is given the cyanide treatment. All Pachuca tanks in the mill are 10 ft. in diameter and 30 ft. high, with 60° conical bottoms. When filled to the level found best for agitating (which is 6 in. below the top of the central column), each tank holds a volume equivalent to 50 tons of water. This is equal to the regular charge of 30 tons of concentrate with 40 tons of solution, although as high as 40 tons of concentrate has been treated as one charge without any difference in extraction results. The floors under the Pachuca tanks, as well as all other floors in the building, are of smooth concrete, sloping to a central sump, supplied with small pumps to return any escaped solution or pump to the proper tanks.

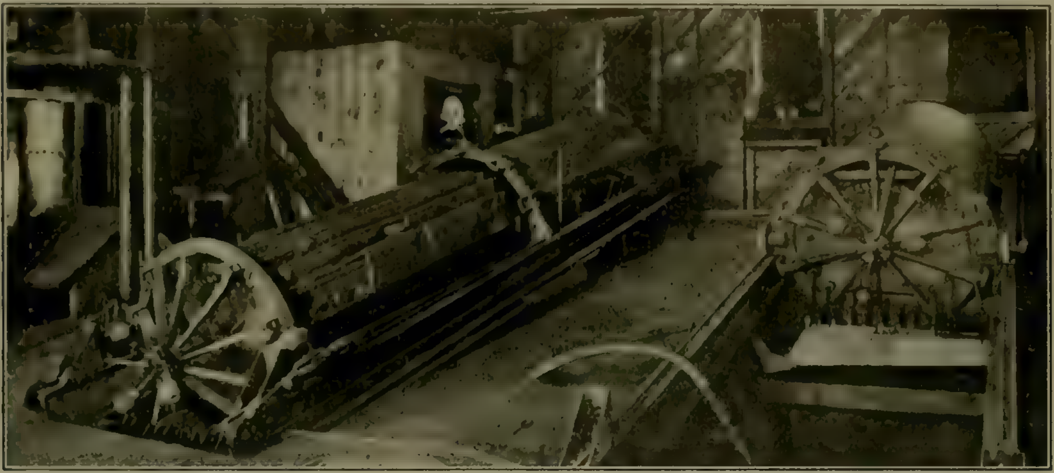


PACHUCA TANK.

The first cyanide treatment consists of 8 hr. agitation in a 2-lb. (0.1%) cyanide solution; either potassium or the mixed cyanides being successfully used. Alkali is kept at 1.25 lb. (0.063%) of lime (CaO) per ton of solution. Lime is added during the treatment if the titrations show below that figure. 18 hr. is allowed for settlement and decantation of this solution. Decantation takes place through a flexible hose, which is made as follows: Canvas coated with tar is wrapped around pieces of old boiler tubing 3 in. in diameter and 4 in. long, spaced ¾ in. apart. The canvas between the short lengths of tubing is wrapped with wire, making the diameter of these spaces slightly smaller than that of the tubing, thus insuring flexibility as well as avoiding the shifting of the tubing. Attached horizontally to the top of the flexible hose is a 3 in. slotted pipe. In operation this slotted intake floats by the aid of two adjustable air-cylinders. The arrangement of these cylinders is such as to allow the vertical adjustment of the intake-pipe to any depth of submergence desired.

The long settlement allowed, with the excessively fine condition of the concentrate, its high specific gravity, from 4.6 to 5.0, and the high alkalinity of the solution, leaves a 30-ton packed mass in the bottom of the Pachuca. This is brought into agitation within 15 min. by a device designated as the 'spider,' which is an adjustable hollow annular casting with radiating fingers, the whole encircling the central agitation-column. When the charge is to be put into agitation the spider is lowered by a small hand-windlass until it rests on top of the settled charge. Air is then turned through the fingers, and at the same time the solution for the next treatment is run into the tank. The device rapidly bores its way to the bottom of the Pachuca, leaving a boiling, churning pulp above, and clearing the way to the bottom opening of the central 10-in. agitating-column. As soon as this is opened and air has been admitted to the inner pipe, the spider is raised from the tank and full agitation of the charge proceeds.

The second cyanide treatment of the charge is with solution drawn from the barren-solution storage-tanks or the wash-solution storage, the cyanide strength being 1.5 lb. (0.075%) per ton of solution. After 2 hr. agitation the air is shut off and almost immediately decantation is started. This decanted solution is pumped directly on to an incoming fresh charge, being strengthened in cyanide as it enters the tank, and becoming the first cyanide solution for the new charge. This cycle in handling solution—barren to wash-solution, then to second cyanide treatment at 0.075% cyanide, then to first treatment at 0.1% cyanide, thence to precipitation and back to barren—gives at each step just the conditions best suited for that step, and is very satisfactory in practical operation. The settled pulp after the second decantation has a specific gravity of 1.8, and is readily agitated by means of the spider, and then discharged into the pulp-storage tank by a Byron Jackson 4-in. centrifugal pump, from which it is drawn to the Kelly filter-press. This thick pulp holds in suspension the sand which would settle through a lighter medium. The storage-tank is conical bottomed, 15 ft. in diameter, and situated at such an elevation that a static pressure of 30 lb. per square inch is exerted at the filter-presses. The pulp in the tank is kept in constant circulation by an air-lift, drawing from the conical bottom and carrying the pulp down close under the filter-presses and back up again over the top of the tank. The pulp as pumped from the Pachuca tanks enters the bottom of this same line, and the whole is thus kept in suspension and circulation past the presses, into which it is intermittently drawn for filter-treatment. The illustration shows the Kelly filter-presses installed to work under a gravity head as described. Above the pulp-storage tank is placed a similar tank for the storage of wash-water, from which a hydrostatic pressure of 25 lb. per square inch is obtained at the presses. This solution is kept in circulation, using the same method as applied to the pulp. The higher gravity of the pulp in the lower tank results in a greater pressure at the presses than that obtained from the wash-solution, although the latter carries a higher head.



KELLY FILTER PRESSES.

Filtering is done in two type 1-B Kelly presses. By opening valves in the circulation-lines directly under each press it is filled with either pulp or wash-solution as desired. The excess pulp or wash-solution from the press-cylinder is returned into its proper line by displacing with compressed air admitted into the cylinder. The amount of wash given depends upon the comminution of the concentrate, the usual pulp being washed with 0.5 ton of solution per ton of concentrate. The cake formed during decantation of the first treatment-solution, being very fine slime and more impervious to wash-solution than the regular pulp, is given 1 ton of wash per ton of concentrate. When filling the press, the contained air is allowed to escape through an overhead pipe attached to the highest point of the press-cylinder. The change in sound of the exhaust indicates to the pressman when the press is full. After drying the cake with compressed air until it contains not more than 10% of moisture, the press is opened and the cakes shaken off with wooden paddles, and then sluiced with water to the tailing-dam. A distributor below the press-launder sends the gold-solution to two gold-sumps and the wash-solution to the two wash-solution storage-tanks. These four tanks, as well as a clarifying-tank which is in the same group, are built of 3-in. redwood, 15 ft. in diameter by 16 ft. deep, and each holds 75 tons of solution.

The wash-solution is pumped to a Pachuca tank as needed, becoming a second-treatment solution. From the gold-tank the solution is drawn into the clarifying-tank, in which are suspended vertically six canvas filter-leaves, all connected to the suction of a triplex 7 by 9-in. Aldrich electric pump, used exclusively for pumping gold-solution through the precipitation-presses. A traveling-belt, driven by ratchet-gears and a pair of eccentrics connected to the pump-drive, feeds zinc-dust into a cone. Here the dust is emulsified with a small stream of gold-solution tapped from the discharge-column of the same pump, and is then drawn into the suction-line. An automatic float in the cone prevents the introduction of air into the pump-suction. The pump raises the solution with the zinc-dust to the upper part of the building and forces it through two 36-in. triangular, 16-frame Merrill presses. An average of 145 tons of solution is precipitated daily, with a consumption of $\frac{1}{3}$ lb. of zinc-dust per ton of solution, equivalent to 0.86 lb. of zinc-dust per ton of concentrate. The average strength of solution before precipitation is 1.25 lb. (0.0625%) of cyanide; 1 lb. (0.05%) of lime, and $9.50 (9.2 dwt.) gold. The barren or precipitated solutions are kept at 10 cents (2.3 grains), or less, gold per ton, and are used for wash-solution or returned to the Pachuca tanks, as desired.

pensating for that received as moisture in the concentrate delivered to the bins. All the solution used in grinding and classifying is drawn directly from the mill-reservoir. The overflow of fine pulp from the back of the Dorr classifier flows at once to the Callow tanks in the lower building, the spigot-product of which empties into one of the 12 Pachuca tanks for treatment.

The specific gravity of the pulp as it enters the Pachuca tanks is 1.5, or a ratio of 1 of concentrate to 1.18 of solution. The charge is agitated for 8 hr., the necessary cyanide and lime being added to bring the cyanide content of the solution to 1.5 lb. (0.075%) and the lime content to 2 lb. (0.1%) per ton. After agitation and settlement, the clear solution is decanted to the gold-tank through the clarifying-press described later, and a fresh charge of barren solution, the same as that used in the grinding, is drawn from the mill-reservoir, brought to the same strength as the previous treatment, and the charge agitated for 4 hours. This is then settled and the solution decanted. Both solutions decanted from the agitators, together with the overflow from the Callow settling-tanks previously mentioned, are drawn by gravity through the clarifying-press before emptying into the gold-tanks. The settled pulp in the bottom of the Pachuca tanks, having a specific gravity of 2, is then agitated by means of the spider and pumped to the pulp-storage tank, from which it is drawn to the Kelly presses for filter-treatment.

(a) During the first period the refinery had not been completed and the precipitate was shipped to a smelter, cost of which is not given.
(b) Assays are made at the central assay office of the combined companies at Treadwell, and charged against the cyanide plant at a proportionate rate per assay.
(c) Electricity, compressed air, and steam are purchased from central power plants, at cost of generation.
(d) Labor, first period, 20 men at $3.75 average wage.
(e) Labor, second and third periods, 22 men at $3 781 average wage. (18 men in mill, 4 men in refinery.)

COST OF CYANIDE TREATMENT, ALASKA TREADWELL G. M. CO.

The Merrill presses are opened when filled or when the pressure exceeds 25 lb. per square inch. Forcing the solution through at higher pressures caused a mechanical loss of precipitate through the canvas. The precipitate is dropped from the press-frames into steel pans and lowered by an electric elevator to the floor below, and thence conveyed by trucks through a concrete passage into the refining-room.

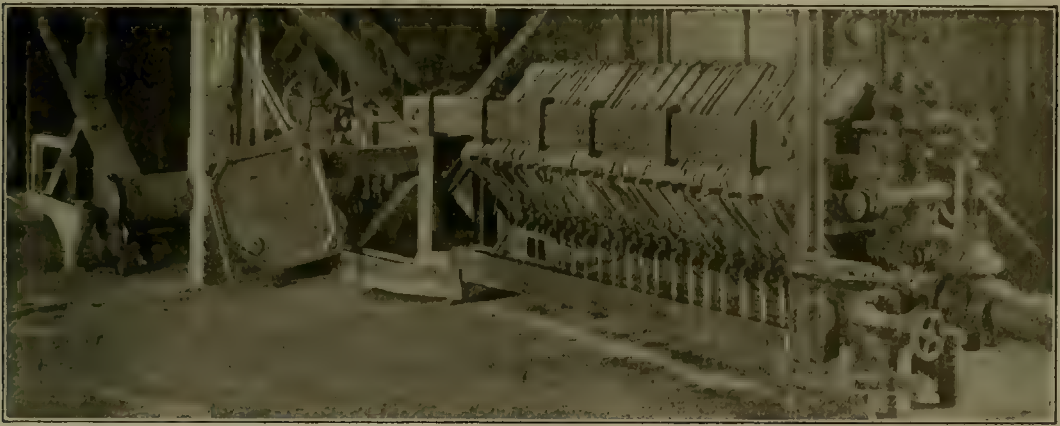
On account of the work required to look after and collect the amalgam, as well as the greater danger of amalgam loss from the pipe-lines and launders, the plates were removed after the first three months' run, and the whole product is now being cyanided directly without amalgamation. In order to handle the larger amount of solution made necessary when grinding in cyanide solution, two 1800-ton steel tanks have been erected, one above and one below the plant. All the precipitated or barren solution flows by gravity from the precipitation-presses to the lower tank. This solution, having an average value of $0.08 in gold, 1.14 lb. of cyanide, and 1.70 lb. of lime per ton, is pumped to the second of these tanks, which is situated 25 ft. above the mill-bins, and acts as the mill-reservoir. Thus at no time is there any cyanide solution run to waste, the solution discharged as moisture in the tailing, plus that absorbed or evaporated in the mill, com-

This method of operation, depending upon the one barren solution for all purposes, keeps the gold-content of the solution to the lowest possible value, which, although contrary to the usual practice, is the object sought in this mill. The solution overflowing from the Callow settling-tanks (containing gold, $10; cyanide, 1 lb.; and lime, 2 lb. per ton) flows by gravity through a special clarifying-press built in the Treadwell shops, the same as receives the decanted solution. This press is of the ordinary plate-and-frame type, yet with a series of ports or channels so arranged as to allow of discharging or sluicing-out a cake without the necessity of opening the press. This sluicing-out press consists of 20 square frames, each 3 in. thick, with the corresponding plates 1 in. thick. The upper channels and two side channels extending through the press have small holes opening into the frame side of the leaf.

The upper small channel allows the introduction of compressed air behind the leaves. The lower triangular channel connects with a 6-in. sluicing-out pipe. The press, with connections, is shown in the illustration with one of the plates standing to the left.

To discharge a cake, water is introduced at the back end of the press through the large triangular opening on the bottom, and flows through the under side to the discharge end, where it empties into the launder leading to the tailing dam. With this passageway clear, compressed air is introduced through the portholes on the plate side of the leaf. The plate corrugations being depressed 0.5 in. leaves a concave surface, in which the cake forms. The air now being introduced behind the leaves by a series of separate knocks or bumps causes the cakes to drop off into the sluicing-out channel, where they are carried away by the stream of water. For the final washing of the leaves, water is introduced through the three upper channels, and, passing through the tapered holes, is sprayed on the two filter-cloths, which bag together by reason of the compressed air introduced from the plate side.

The method of feeding the zinc-dust has been changed somewhat from that originally installed. The reasons for these changes were to create a more even feed of zinc, to do away with the air previously used in the emulsion-cone, and not only to break up any lumps, but to brighten the zinc and grind it even finer. To do this, the drive from the zinc-belt was taken from the Aldrich pump to a small counter-shaft, which was, in turn, belted to a worm-gear for the drive of the zinc-belt, the belt discharging its zinc directly into a small tube-mill 6 ft. long, made from 10-in. pipe, the cast-iron caps of which were turned to run in rollers. This tube is filled with rods of cast zinc 2 inches in diameter. These rods not only grind the zinc to a more uniform product, but may themselves aid precipitation to a slight extent.



TREADWELL SLUICING CLARIFYING FILTER.

Considerable annoyance is occasioned by the clogging of the cloths in the Merrill gold-presses and by the accumulation of precipitate in the entire line from the zinc-feeder and pump to the presses. Filter-cloths of several kinds—heavy duck at 31c. per yard, various grades of drilling at from 9 to 15c., and muslin sheeting at 7c.—have been tried. The lightest and cheapest muslin is now in use, with results no worse than obtained with the more expensive grades.

From the moment of contact of the zinc-dust with the gold-solution, trouble is caused by the slime or precipitate incrusting everything touched. The interior of the pipes gradually becomes smaller in area, even though the solution is driven through at a constantly increasing velocity. After three months' use a 6-in. pipe of 28 sq. in. area was so filled with caked precipitate that only a triangular opening of 4 sq. in. remained. From 80 ft. of this pipe, $25,898 was recovered. Being desirous of operating the Merrill presses more or less intermittently without the necessity of each time closing the cocks to retain the solution, which if allowed to drain not only oxidizes the zinc, but causes the precipitate when the pressure is removed to settle in a mass at the bottom of the press frames, consequently not allowing the greatest amount of solution to pass through the unoxidized zinc, the discharge cocks were removed from the plates, and open pipes discharging into a launder on top of the presses were substituted, as shown. The result of the several changes is a more uniformly low tailing solution, with the consumption of less zinc, while the gold value of the precipitate has been raised from $15 to $25 per pound; hence a corresponding lowering of refining charges.

MERRILL PRECIPITATION PRESSES.

The refinery, adjoining the mill, is 30 by 76 ft. in area; constructed of reinforced concrete with steel-truss roof covered with corrugated iron. The precipitate entering the refinery is crushed through 0.5-in. screen, made up into lots of from 1000 to 1200 lb., weighed, sampled, and charged into one of two redwood tanks, 8 ft. in diameter and 9 ft. deep, conical bottomed, and lined with sheet lead. The tanks are built on the plan of a Pachuca tank, with a central column of wood fitted with lead pipes carrying steam and compressed air for heating and agitating the solutions.

In these tanks the precipitate is treated with acid to dissolve out the zinc, lime, etc. About 1 lb. of 66° sulphuric acid is required per pound of precipitate, and is added in the following manner: About 2 tons of water is introduced into the tank, steam turned on, and the water brought to the boiling-point. Air is turned on the central air-lift, and the acid-valve opened. The acid flows in by gravity, while the precipitate is shoveled in at the rate of 2 lb. of precipitate to each pound of acid. When all the precipitate and from 50 to 60% of the acid have been added, the acid valve is closed and the charge agitated until the acid is entirely neutralized, which generally occurs within 30 min. The tank is then filled with water, and the charge allowed to settle for about 2 hr., after which the clear solution is siphoned off into a filter-tank. The latter is 8 ft. in diameter and 4 ft. deep, having a false bottom of 1-in. strips, placed 12 in. from the bottom of the tank and 1½ in. apart. The strips are covered with heavy iron screen, 1-in. mesh, on which is a bed of burlap 1 in. thick, one thickness of mill blanket, one thickness of light canvas, and a bed 1 in. thick of quartz sand screened between 20 and 80-mesh. The sand is divided into sections of 8 by 10 in. by a light wooden frame, covered by a single thickness of drilling, the latter forming the working-surface of the filter. The solutions filter freely through this medium, the clear filtrate being run into one of three storage-tanks, where it is held until a sample has been assayed, and then run to waste through a series of zinc-boxes. All solutions and wash-waters from the refinery are disposed of in this way.

After decanting the first acid the precipitate in the tank is given two washes of boiling water. Just enough water to enable the charge to be agitated is then added, and the remainder of the acid run in rapidly. This gives a solution containing from 15 to 18% of acid, agitation being continued until the acidity ceases to decrease, which usually leaves about 1% of free acid. The tank is then filled with water, settled and decanted as before. This solution, containing from 50 to 75 lb. of free acid, is at present run to waste.

The charge now receives three or four washes of boiling water followed by washes at about 30°C. temperature, until the wash-water gives no reaction for sulphates with barium chloride, which is generally after 15 washes. After decanting the last wash, the charge is sluiced through a valve in the bottom of the tank on to the filter, which has been thinly covered with silica sand to aid filtration, where the excess water is removed by means of a vacuum-pump. The slime is removed to a large wrought-iron pan, placed upon a 4 by 8-ft. steam-table, inclosed by a sheet-iron hood. When nearly dry but still damp enough to prevent dusting, the slime is rubbed through a ½-in. screen, weighed and sampled, the weight of the acid-treated product being from 25 to 33% that of the original precipitate. Each lot of precipitate is analyzed before and after the acid treatment, which enables a close calculation to be made of the amounts of fluxes required for the monthly melting.

The percentages of the principal substances contained in an average analysis of the precipitate before and after acid treatment are:

	Before, %.	After. %.
Au	5.08	17.34
Zn	42.93	5.15
Pb	8.08	20.09
Cu	6.19	14.28
CaO	10.51	1.89
Fe	1.10	0.52
S	1.41	7.62
Insoluble	3.48	22.85

The high percentage of insoluble after treatment is due to the silica added to the lot just before filtering.

At the end of the month the various lots of acid-treated precipitate are united and the various fluxes added. The melting is done in a specially constructed oil-burning furnace. For melting purposes the furnace is fired with a reducing flame. The crucible of hearth used for the melting is 4 by 3½ ft., lined with either magnesite brick or fire-clay, according to the fluxes used. This hearth is placed on a steel car and run under the furnace. Jackscrews, operated by hand-wheels at the four corners of the car, allow of raising the hearth to form the furnace-bottom.

From the fire-box at one end of the furnace the heat is drawn across the top of the charge, being reflected downward by the arch roof and the down-draft to a dust-condensing chamber. The furnace is charged with precipitate hourly, the slag and lead bullion being tapped off intermittently from opposite sides of the hearth. The month's clean-up, amounting to 1450 lb. of acid-treated precipitate, or a total charge, including fluxes, of 2600 lb., is melted on this hearth in 36 hr., and requires the attention of but one man per shift. A typical mixture of fluxes is:

	Pounds.
Acid-treated precipitate	100
Borax glass	22
Sodium carbonate	25
Old slag	80
Iron-turnings	15
Powdered graphite (old retorts)	3

Such a charge will produce about 35 lb. of metal, from 10 to 15 lb. of matte, and from 160 to 180 lb. of slag. From 150 to 300 lb. of high-grade copper matte is produced each month. This matte is roasted and allowed to accumulate until there is sufficient to make up a charge, when it is mixed with litharge, fluxed, and melted to produce lead bullion, which is the work-lead used for the removal of copper in cupellation. After melting either precipitate or matte, the slag is tapped into conical pots holding about 200 lb., with a tap 4 in. from the bottom, through which the molten core is drawn off. The shells, containing most of the metallic content, are dumped, crushed, and used in fluxing a later charge. The cores, constituting 75% of the total slag, are sampled, sacked, and stored for shipment to the smelter.

The cupellation is done on a limestone test the same size as the melting-hearth, it being run under the furnace on the car previously described. For cupellation the furnace is fired with an oxidizing flame, while free air is introduced over the test by means of a connection from a compressed-air main through a needle-valve discharging into the open end of a 4-in. pipe. This produces low-pressure air, which is introduced into the furnace on the opposite side from which the molten litharge is tapped off. The fine bullion resulting from this cupellation is drawn off and remelted in Faber du Faur tilting-furnaces into bars of 1000 oz. each. The average fineness of the cupelled gold is 880. The retorts of the Faber du Faur furnaces are supported on two 1½-in. iron pipes built into the furnace, through which cold water is kept circulating. These pipes have proved very satisfactory.

In conclusion, the cyanide-plant has now been in operation one year, using the machines and equipment originally installed, with the exception of the abandoned amalgamation plates, the substitution of larger tube-mill motors, and the addition of the 'Treadwell' clarifying-press, with results summarized in the table. During the month ended August 15, and not included in cost-sheet, 2010 tons was treated, at a cost of $2.8764 per ton, and an estimated extraction of 97.025%, as compared with the experimental estimates of $3.25 per ton and 96% extraction.

Classification at the Portland Mill

The work of the new mill of the Portland Gold Mining Co. at Victor is of much interest, and Thomas Crowe, the superintendent, has recently given out the results of a series of tests on the Dorr classifiers, employing a greatly increased feed. By feeding a pulp containing 5 solution to 1 of solid to the classifier at the rate of 145 tons per day the following interesting results were obtained. The feed had the following screen analysis: +40, 12.2%; +60, 16.8; +100, 9.3; +200, 13.4; −200, 47.1.

	1.	2.	3.	4.
Slime.	%	%	%	%
+100	0.2	0.7	1.6	1.7
+200	6.4	9.4	5.4	9.7
−200	93.4	89.9	92.9	90.3
Sand.				
+ 40	26.5	28.0	25.8	36.9
+ 60	29.1	30.0	30.5	30.6
+100	13.2	17.6	16.4	13.8
+200	18.5	14.8	17.6	12.8
−200	12.0	9.6	8.5	6.1

Gold Production of California

By Charles G. Yale

*A few years ago somebody connected with one of those self constituted bodies of unofficial character Chamber of Commerce, Board of Trade, or State Development Board started a catch phrase referring to California as 'The Land of Sunshine, Fruit, and Flowers,' and the railroad magazines and folders keep it steadily in use, working day and night. Yet it altogether ignores the substance which brought California into the Union, which peopled it, and which made it famous throughout the world. All you who come from what we out here call 'the East,' have in your own States, no matter which, sunshine, fruit, and flowers. But your Eastern States, though having these things as we do, have not the gold that we do. Therefore, the old designation of the 'Golden State' applied to California, should be revived, as being the most distinctive term. It is worthy of remembrance, too, that during the dark days of the Civil War this State produced $172,000,000 in five years in yellow gold, and saved the credit of the Nation.

Gold mining has been carried on in California since

"The days of old,
The days of gold,
The days of '49."

and still continues. Since that historic year, and up to the end of 1910, the State has produced, in gold alone, $1,527,930,062. Since 1792 the entire United States' production of gold has been $3,065,631,000, so that the single State of California has, during that period, produced approximately one-half of all the gold from Alaska, Arizona, Colorado, Idaho, Montana, Nevada, New Mexico, Oregon, South Dakota, Utah, Washington, and the Southern and scattering States. In other words, in 118 years all the other twenty-five gold-producing sections of the United States combined have only produced about the same amount as the single State of California has. Moreover, it has taken California but 62 years to produce its quota; which it has done at the average rate of $24,644,033 per year, or an average gold yield of $2,053,669 per month for the last 62 years. Has not California earned its title of the 'Golden State'?

It is to be noted, moreover, that California is still the leading gold producer among the States of the Union, and there are still a larger number of producing gold mines here than in any other State. Gold is being mined here in larger or smaller quantities in 34 of the counties of the State. Among other mining States of the Union, California has, as a gold-producing region, the distinction of holding the record on all counts. It has made by far the largest aggregate product; made the largest output in any single year; made the highest annual average, although its mines have been worked over 62 years; kept the lead as a gold producer the greatest consecutive number of years; has the largest number of individual gold mines; pursues the greatest number of varied branches of gold mining; and has the widest geographical distribution of its gold deposits. These are reasons why California deserves its title of the 'Golden State', and why all other designations seem absurd and trivial.

The gold belt of the State extends from Oregon on the north to Arizona and Mexico on the south—its extreme length. Gold is mined in the highest parts of the Sierra Nevada mountains, the foothills, the valleys, and on the beaches bordering the ocean. The gold is taken from quartz, placers, pockets, seam diggings, hydraulic, drift, ocean-beach sand, by dredging, wing-damming, dry-washing, and other forms of mining. The snowy ranges, the river beds, the beaches, the desert sands, the ancient buried rivers, the superficial gravel deposits, all yield their quota. The climatic conditions in all except the higher ranges are favorable to work the year round. In some of the foothill counties, the men work their orange or olive orchards and vineyards in the summer and drive for gold under them in the winter months. It is to be noted that today the three great dredging fields are at points where citrus fruits first ripen. The county producing the most gold is in the valley, below the foothills, and not in the snowy mountains.

It is not my intention to read you a statistical paper or bore you with many figures, but rather to endeavor to convey an idea of the present condition of the gold-mining industry in the State, so far as it may be done in a brief paper, and a few figures are necessary. It may be stated that the record year of gold production in the State was 1852, when the placer miners dug out $81,294,700. In 1883 the yield was $24,316,873, and then the annual product gradually declined, owing largely to the closing down of hydraulic mines, until in 1889 the output was only $11,212,413. For seven of those years, between 1883 and 1904, it was less than $13,000,000 annually. Since 1904, the gold yield has averaged about $19,000,000, sometimes over $20,000,000, and it is to be confessed there is not much prospect of an increase at present. With labor at $3 per day, and an 8-hour day law, it is difficult for the quartz miners to make much profit on ore of ordinary grade, unless large orebodies are worked, and many have been compelled to cease operations. Still the tonnage from the deep mines continues to be of considerable proportions, having been 2,697,885 tons last year, of which 1,963,296 tons was silicious, or gold ores. The average content in gold of this ore was $5.20 per ton. In some counties, where the veins are comparatively small, the content reaches to $8 per ton. Taking a typical large mine in one of these counties where nearly 100,000 tons were milled, the average yield per ton was $13.68, and the profit $7.51 per ton, above all costs of operation and development.

In the Mother Lode counties, where the orebodies are very wide, the ore is low grade. In one of these counties last year 547,873 tons of ore was milled, yielding an average of $4.69 per ton. But taking all five of the Mother Lode counties, where 1,170,497 tons was milled, the average yield per ton was only $3.78.

It may be a surprise to some to know that, contrary to general supposition, the placer mines of the State are now yielding 45.09% of the entire gold product, the deep or quartz mines producing 54.91%. About this proportion has prevailed for several years. It is true that the ordinary surface placers, where they use rocker, tom, and sluice, now cut but a small figure, but the drift and hydraulic mines are still yielding, and the dredges are now producing 84.94% of all the placer gold. This comparatively new system of surface mining has given renewed life to placer work. The hydraulic mines, formerly highly productive, now, owing to adverse legislation, are yielding only 7.15% of the placer gold, the drift mines 5.82%, and the surface or sluicing mines only 2.09%. Since 1899 the dredges have dug out $40,318,775 and are now producing at the rate of $7,550,000 per annum, with 71 machines in operation. The details of this dredging work have been given by Charles Janin in another paper. The largest production of gold in California last year came from Yuba county, mainly from dredging. The most productive in gold from deep mines is Amador, one of the Mother Lode counties. The leading hydraulic mining county is Trinity, and the leading drift mining county is Placer. The largest production from dredge mines was from Yuba county.

It is to be confessed that little progress is being shown in the deep mining for gold, or even in the placer fields, aside from dredging operations. There are only three large dredging fields in the State, these being at points where the Feather, American, and Yuba rivers leave the foothills to enter the valley lands, after having, in their course, cut through beds of auriferous gravel, and depositing the fine gold with the soil carried down when the streams are suddenly arrested from their swift flow by reaching level ground. There are numerous isolated points, however, in

---

*A paper presented at the San Francisco Meeting of the American Institute of Mining Engineers.

other counties, where the circumstances permit the operation of one or more dredges within restricted areas. For this reason dredging is being carried on in 10 counties of the State.

The speculative era of gold mining has almost entirely disappeared from this State. The stock of not a single gold mine of California is listed on the Stock and Exchange boards, or publicly dealt in. The mining work is now almost entirely carried on by organized companies which provide capital for the enterprise. The day of the nomadic miner is virtually at an end, and the men are now nearly all employed at daily wages. Of course, there are still many prospectors, but most of the miners live in permanent thriving towns near the larger properties, far different from the old-fashioned primitive mining camp. High-priced officials have been dispensed with, office force and expenses reduced, and only skilled men employed. More railroads, better wagon-roads, cheaper supplies, improved methods of transportation, better machinery at lower cost, greatly improved reduction methods and appliances, adoption of proved modern processes, careful saving of concentrate, stronger powder, power-drills, electric and water-power, heavier and larger milling plants, more extensive development, and generally improved systems and appliances have all contributed in recent years toward a change for the better in gold mining in California.

Utah Metal Production in 1910

The total value of the mine output of gold, silver, copper, lead, and zinc in Utah in 1910, according to V. C. Heikes, of the United States Geological Survey, was $32,199,185, against $31,380,092 in 1909.

The total gold production in Utah in 1910 showed a decrease in value of $174,463, or 4.3%. The largest producer of gold was Salt Lake county, which yielded $1,776,058, against $1,780,573 in 1909. The West Mountain or Bingham district produced $1,767,992 of the gold credited to Salt Lake county and 43.8% of the 1910 Utah gold output. Juab county produced $1,181,366 in 1910, against $1,448,096 in 1909, and Utah county $193,234 in 1910, against $276,314 in 1909. The Tintic district, which is partly in Juab county and partly in Utah county, produced $1,370,320, or 34% of the gold production of Utah in 1910. Tooele county produced $721,361 (of which all except about $5000 came from the Camp Floyd district) in 1910, against $820,486 in 1909.

The silver production of Utah in 1910 showed a decrease of 1,250,201 oz., or 10.7%. Juab county produced 3,835,062 oz. in 1910, against 3,544,918 in 1909, and Utah county 1,500,625 oz. in 1910, against 2,995,658 in 1909. The Tintic district silver yield declined from 6,404,847 oz. in 1909 to 5,222,742 in 1910. Salt Lake county produced 2,006,131 oz. in 1910, against 1,780,572 in 1909. Of the Salt Lake county yield, the West Mountain or Bingham district contributed 1,800,410 oz. in 1910 and 1,615,394 in 1909.

The silver output of the Park City mining region in 1910 was 2,571,771 oz., a decrease of 253,614, or 10%, from that of 1909.

Copper production increased in Utah 18,649,261 lb. in 1910, a larger increase than in any other of the copper-producing States. The Bingham district produced 113,725,280 lb. of copper in 1910, against 92,560,340 in 1909, 71,155,740 in 1908, and 45,431,964 in 1907. The Tintic district yielded 8,993,036 lb. in 1910, against 5,915,669 in 1909, an increase of 3,077,367 lb. The Park City district, in Summit and Wasatch counties, produced 1,423,629 lb. in 1910, against 1,655,749 in 1909.

The production of lead in Utah in 1910 was 123,324,635 lb., valued at $5,426,284, against 148,486,463 lb., valued at $6,384,918, in 1909. Of the 1910 output, 30.9% was derived from mines in the Park City district, which produced 38,129,761 lb., against 46,350,390 in 1909. The Bingham or West Mountain district produced 30,271,016 lb. in 1910, about the same quantity as in 1909, and 24.5% of the total Utah lead output. The Tintic district, which yielded 56,502,209 lb. of lead in 1909, produced only 37,553,455 in 1910. This district yielded 38% of the Utah lead in 1909, and only 30.4% of that in 1910.

The zinc production of Utah was 16,367,104 lb., valued at $883,824, in 1910, against 9,860,778 lb., valued at $532,482, in 1909. This shows an increase of 6,506,326 lb., or 66%. The Park City mining district alone produced 9,437,992 lb. of zinc in 1910, against 6,737,237 in 1909. This district yielded in 1910 over 57.7% of the total zinc production of Utah. The Bingham district was also a large producer and increased its output from 649,542 lb. in 1909 to 3,572,347 in 1910. Tooele county, which produced 2,843,032 lb., and Beaver county, which produced 513,733, were the only other counties in Utah reporting a production of zinc in 1910. The zinc in concentrates, amounting to 12,959,422 lb., all came from Salt Lake, Summit, and Wasatch counties.

There were 183 mines producing gold, silver, copper, lead, or zinc in 1910, against 179 in 1909. Of these, 8 were small placers. The number of producing mines in the Bingham district was 31; Tintic, 40; Big and Little Cottonwood, 17; Park City, 17. The total quantity of ore sold or treated in Utah in 1910 was 6,389,398 short tons, an increase of 1,266,809 tons. The average total recoverable value per ton was $5.02 in 1910, against $6.12 in 1909. The lower average value per ton was caused by the large increase in copper ores, of which 5,417,558 tons were sold or treated in 1910. This quantity was 84% of the total ore treated and an increase of 1,201,332 tons over the 1909 production of copper ores.

Of the total tonnage of all classes of ore 263,041 tons, mostly from Tooele county, went to gold and silver mills, 5,182,057 tons, of which 4,937,285 tons were from Bingham district, went to concentrating mills, and 896,834 tons were sent to smelters. It is interesting to note that Salt Lake county produced over half of the total metal production, by value, chiefly from its copper, having furnished 90% of the total production of that metal and $^6/_7$ of the total tonnage of ore treated.

MINE PRODUCTION OF GOLD, SILVER, COPPER, LEAD, AND ZINC IN UTAH IN 1910, BY COUNTIES.

[By Victor C. Heikes, U. S. Geological Survey.]

Counties.	Ore treated, Tons.	Gold.*	Silver,* Fine ounces.	Copper, Pounds.	Lead. Pounds.	Zinc, Pounds.	Total value.
Beaver	83,748	$17,114	339.881	1,128,785	6,235,535	513,733	$646,111

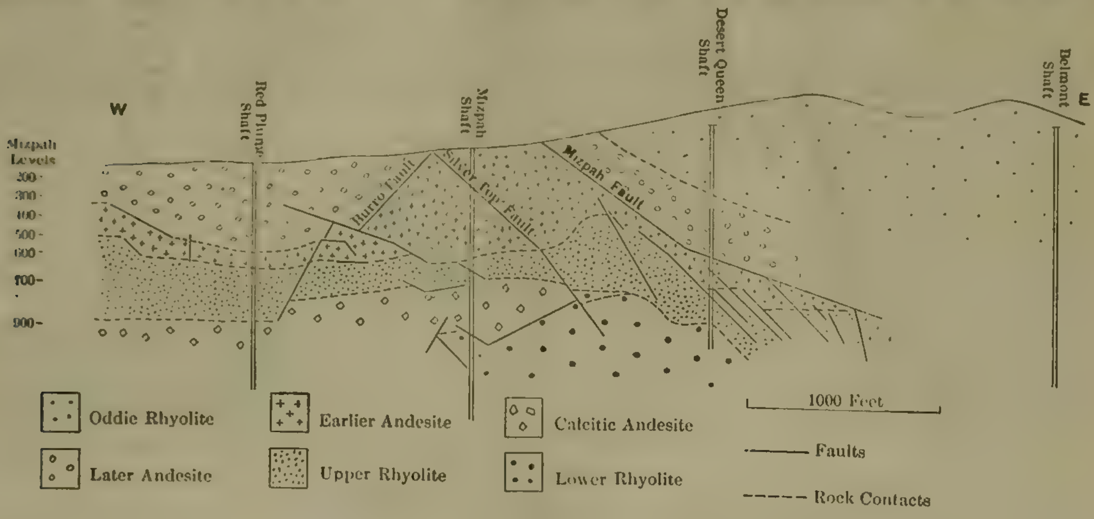
The Geology of the Tonopah Mining District

By Augustus Locke

*The important geological publications concerning the Tonopah mining district are those of Spurr and of Burgess. In these publications are presented fundamental differences of interpretation, which are the more interesting because both authorities have had ample opportunity for observation, and because both are geologists of proved ability. The general geological features of Tonopah are shown in Fig. 1, and the differences of interpretation referred to are outlined in the accompanying notes. Briefly, Burgess regards the various rocks as flows, lying in the order of their deposition. Spurr regards them in part as flows, and in part as flat-lying intrusives. The disagreement, then, concerns the rocks regarded on the one hand as intrusives, and, on the other hand, as flows. These rocks are chiefly the so-called calcitic andesite, the upper rhyolite, and the lower rhyolite. The economic importance of the question of interpretation is, of course, limited to its bearing on the probable distribution of undiscovered ore. The later andesite is generally conceded to be barren—a 'cap rock,' at whose lower contact the productive veins apex. The earlier andesite has so far yielded the bulk of the production. As has already been suggested, both Spurr and Burgess regard it as a flow, and both have essentially the same conception of its distribution. Above the bottom of the earlier andesite, therefore, the conception of the ore distribution is the same, whichever interpretation be adopted. Below the bottom of the earlier andesite, however, the matter of interpretation assumes supreme economic importance; for, while Burgess regards all the underlying rocks as older than the earlier andesite, and older than the chief ore mineralization, Spurr regards them as younger than both. Under Spurr's hypothesis, exploration in these rocks is emphatically discouraged; under Burgess', it is to a certain extent encouraged.



Geologic column of rocks shown in section (youngest at top).

Spurr (1910).		*Burgess.*
Oddie rhyolite (partly intrusive).		Oddie rhyolite.
Lower rhyolite.		Later andesite.
Later andesite.	} probably identical.	Earlier andesite.
Calcitic andesite (intrusive).		Upper rhyolite.
Upper rhyolite (intrusive).		Calcitic andesite.
Earlier andesite.		Lower rhyolite.
